The preparation, properties and uses of glycerol derivatives. II. Acetals, amines and resins. A. Fairbourne, G. P. Gibson and D. W. Stephens. *Chemistry and Industry* **49**, 1069–70(1930).—The acetals were prepared from glycerol and aldehydes or ketones in the presence of HCl. These compds., mainly mixts. of isomers, are obtained in good yields, and are good solvents for cellulose esters, resins, gums, and org. substances generally. The following gives b. p., d_4^{25}, n_D, soly. in H_2O: Methylideneglycerol, b_{760} 195°, b_{20} 95–7°, 1.215, 1.450 (19°), miscible. Ethylideneglycerol (from $C_2H_4(OH)_2$ + glycerol), b_{760} 180–197°, b_{40} 96–116°, 1.131, 1.442 (25°), miscible. Isopropylideneglycerol, b_{760} 201°, b_{40} 107–8°, 1.063, 1.435 (25°), miscible. Benzylideneglycerol, b_4 145–52°, 1.190, 1.536 (23°), less than 1%. A mixt. of mono-, di- and triglyceryl-amines is obtained from $CH_2(OH)CH(OH)CH_2Cl$ and $NH_4OH + NH_3$ (15° for 24 hrs.). The product contains 10–11% N. The dichlorohydrin gives analogous results. These bases combine with fatty acids to give soaps sol. in org. liquids. Treatment of these amines with Ac_2O, abietic or phthalic acids gives resins, sol. in C_6H_6. These may be

valuable in lacquers. Rosin may be rendered fit for use in lacquers by addition of a little glycerylamine to neutralize acidity. G. R. YOHE

The preparation of some dimethylamino fatty acids. V. PRELOG. *Collection Czechoslov. Chem. Comm.* **2**, 712–22(1930).—*Dimethylammonium acid succinate*, $C_8H_{15}O_4N$, m. 159–60°, was prepd. from a mixt. of equiv. amts. of aq. Me_2NH and $C_4H_6O_4$. *Dimethylammonium acid adipate*, $C_8H_{17}O_4N$, obtained similarly, m. 75°. These salts were heated just below the decompn. point to complete loss of H_2O vapor, and the product was distd. *in vacuo*. *Succinic bisdimethylamide*, $C_8H_{16}O_2N_2$, m. 80–1°, and *adipic bisdimethylamide*, m. 85°, were isolated from the distillates. The distillates subjected to electrolytic reduction gave about 40% of the *monoamide* and about 10% of the *diamine*, *N,N,N',N'-tetramethyl-1,4-diaminobutane*, b_{740} 168° (*picrate*, m. 198–9°; *chloroplatinate*, m. 233.5° (decompn.); *chloroaurate*, m. 207°); *N,N,N',N'-tetramethyl-1,6-diaminohexane*, b_{732} 208.5° (*picrate*, m. 163–4°; *chloroplatinate*, m. 222°; *chloroaurate*, m. 169°). The reduction of succinic dimethylamide also yielded *4-dimethylaminobutyric acid*, $C_6H_{13}O_2N$ (I), b_{10} 135–7°, b_2 145–50°, m. 102–4°; *HCl salt*, hygroscopic, m. 145–7°; *chloroaurate*, m. 151–2°. Crude I (50 g.) treated with 250 g. EtOH, satd. with HCl and the product dried and distd. gave 70% of the Et ester of I, d_{15} 0.9187, n_α 1.42414, n_D 1.42640, n_β 1.43226, n_γ 1.4371. Crude I (1.3 g.) in 10 cc. MeOH was treated 24 hrs. with 1.7 g. MeI and the I pptd. with Ag_2O. From the filtrate concd. on the H_2O bath there was obtained *4-dimethylaminobutyric acid methohydroxide*, $C_7H_{15}O_2N$, m. 77°; *chloroplatinate*, m. 225–6°; *chloroaurate*, m. 184.5° Prolonged desiccation at the fusion point gave the corresponding *betaine*, m. 219° The reduction of adipic dimethylamide similarly yielded *6-dimethylaminocaproic acid* (II), m. 107–9°; *HCl salt*, hygroscopic; *chloroaurate*, m. 97–9°. The *methohydroxide* (III) of II m. first 115°, and after solidification 254–5° and had the compn. $C_9H_{19}O_2N$, *chloroaurate*, m. 149°. The distn. of III gave the *Me ester* of II, b. 209–10°. R. B.

Tautomerism of α-diketones. H. MOUREU. *Ann. chim.* [10], **14**, 283–405(1930); cf. *C. A.* **23**, 1339, 2705, 4214, 4215, etc. A connected account is given of previously published results. BEN H. NICOLET

Acetoacetic ester condensation. II. Reaction of aliphatic esters with sodium. JOHN M. SNELL AND S. M. MCELVAIN. *J. Am. Chem. Soc.* **53**, 750–60(1931); cf. *C. A.* **23**, 5468.—A study is reported of the action of Na and AcOEt (I), $EtCO_2Et$ (II), $PrCO_2Et$ (III), iso-$PrCO_2Et$ (IV) and Me_2CO_2Et (V) in Et_2O, C_6H_6 and excess of the ester, at the b. p. of the solvent. The Na salts were decompd. by 35% H_2SO_4 and the acid fraction was extd. with 20% Na_2CO_3. The following fractions were dctd. and the yields (in g.) are given in this order: RCOCOR, RCH(OH)COR, higher-boiling products, RCO_2H and higher acids. In Et_2O: I (88 g.), 3, 10, 23, 2, 7; II (102 g.), 5, 30, 14, —, —; III (116 g.), 5, 52, 7, 3, —; IV (116 g.), 3, 54, 2, 4, 4; V (100 g.), 21, 41, —, —, —. In C_6H_6: II (102 g.), 4, 17.5, 10, 1, 3; III (116 g.), 5, 44, 13, 3, 2; IV (116 g.), 6, 48.5, 3, 4, 9; V (50 g.), 5, 20, —, 3, —. Data are also given when an excess of the ester is used as the solvent. There is no perceptible difference in the rate at which the 3 esters, III, IV and V, react with Na nor is there any great difference in the completeness with which they react in the inert solvents to form diketones and acyloins. The need, therefore, of a special mechanism to account for the slowness and incompleteness of reaction of those esters which cannot enolize does not exist (cf. Scheibler and Emden, *C. A.* **18**, 389). It is also evident that the diketone is an intermediate product in the formation of the acyloin rather than the result of an oxidation of the acyloin (cf. Egorova, *C. A.* **23**, 2935). The reaction is therefore formulated as: $2RCO_2Et + 2Na \longrightarrow [RC(ONa)OEt]_2$; $[RC(ONa)OEt]_2 + 2Na \longrightarrow [RC(ONa):]_2 + 2EtONa$. With an excess of ester as the solvent, the acetoacetic ester condensation takes place with I and II; with III very little of the diketone and acyloin, but considerable higher-boiling material with the characteristic yellow color of the diketones is produced; with IV, the combined yield of diketone and acyloin is only about 13% lower than those obtained when C_6H_6 was used but the amt. of higher-boiling material is correspondingly higher; the very high yield of the acyloin and the absence of any diketone in the case of V must be due to the favorable conditions for the reaction when the ester is used as the solvent. The fact that the diketones are readily polymerized and rearranged by EtONa indicates that they are responsible, in part at least, for the high-boiling materials. The acids, RCO_2H, may be due to the hydrolysis of the salt of the ortho ester; this is supported by the fact that high yields of acids were obtained in each case when an excess of the ester was used as a solvent. C. J. WEST

Ethyl aminomalonate and its derivatives. R. LOCQUIN AND V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1274–9(1930).—After many unsuccessful attempts to reduce HON C-

$(CO_2Et)_2$ (I) with the object of prepg. *Et aminomalonate*, $CH(NH_2)(CO_2Et)_2$ (II), the reduction was finally accomplished as follows: 5/3 of the theoretical quantity of Al foil (0.3 mm. in thickness) was amalgamated and added to I in Et_2O. To the agitated mixt. maintained at the b. p. of the Et_2O, water was added, little by little, in a quantity equal to 6 times the wt. of the Al. The Al was in this way obtained as a powder; it is due to this that the reduction was successful. The Al and Et_2O were removed by filtration and distn., resp., leaving a 65% yield of II, b_{12} 116–8°, b_{16} 122–3°. Because of the instability of II, it is advisable to isolate it in the form of the *oxalate*, $H_2(CO_2H)_2$, m. 138°, which may be converted into II by means of K_2CO_3 soln.

I. M. LEVINE

Mercuration of compounds containing the reactive methylene group. K. G. NAIK AND C. C. SHAH. *J. Indian Chem. Soc.* 7, 655–62(1930).—$CH_2(CO_2Et)_2$, mercurated by the method of Neogi and Chatterjee (*C. A.* 22, 4112) gives *Et dichloromercurimalonate* (I), m. above 300°. I boiled with HCl yields *Et monochloromercurimalonate* (II), which turns grey at 192–5°. II is formed from I and aqueous KI; boiling I with alc. KI 0.5 hr. removes both Hg atoms. Mercuration of malonamide yields *dichloromercurimalonamide* (III), which shrinks at 191–2° and m. 220° (decompn.). III and Br water give dibromomalonamide. The following *dichloromercurimalondialkylamides* were prepd. similarly: *methyl*, m. 241° (decompn.); *ethyl*, yellows at 191°; *propyl*, m. 173–5°; *butyl*, m. 90°; *isobutyl*, m. 108–9°; *amyl*, m. 143° (decompn.); *isoamyl*, m. 105°; *heptyl*, (IV) m. 117°. IV boiled with alc. KI loses both Hg atoms; heated with HCl it gives malondiheptylamide. *Malondiamylamide*, prepd. by the method of Backes, West and Whitely (*C. A.* 15, 2070) in 80% yield, m. 126°; *malondiisoamylamide*, prepd. similarly in 20% yield, m. 55°.

A. F. SHEPARD

Synthesis of diisopropylmalonic acid and some related compounds, with observations on the polar character of the isopropyl radical. FREDERICK C. B. MARSHALL. *J. Chem. Soc.* 1930, 2754–61.—The mixt. of 90% of the mono- and 10% of diisopropylcyanoacetic ester produced by Hessler's method (*C. A.* 7, 3506), treated with more Na and Me_2CHI gives 95% of the diiso-Pr deriv., b. 238–41°. $NCCH_2CO_2Et$ with 2 equivs. of EtONa and Me_2CHI give a mixt. contg. 40% of the dialkylated ester. Hydrolysis of the ester with 33% KOH gives *diisopropylcyanoacetic acid*, m. 97.5° (*Ag salt*); KOH fusion gives *diisopropylacetonitrile*, b. 170–1°, d^{23} 0.8105, n_D^{23} 1.4158; hydrolysis with concd. H_2SO_4 at 100° for 20 hrs. gives *diisopropylmalonamic acid* (I), m. 168° (decompn.) (*Ag salt*). *Diisopropylacetamide*, m. 149°. I and CH_2N_2 or Me_2SO_4 on the Ag salt and MeI give the *Me ester* of I, m. 105°; with nitrous fumes this gives the *Me H ester* of II, m. 110°, hydrolyzed by 45% KOH in 36 hrs. to *diisopropylmalonic acid* (II), m. 197° (decompn.); Ag salt; Cu salt, deep blue; heating gives *diisopropylacetic acid*, b_{760} 214°, d^{20} 0.9106, n_D^{20} 1.429 (*Ag salt*). *Et isopropyl-α,γ-dimethylisopropylmalonate*, b_{760} 258–9°, d^{20} 0.9594, n_D^{20} 1.4380; *Et H ester*, b_{20} 152–8°, d^{20} 1.015, n_D^{18} 1.455. The inability to introduce a 2nd iso-Pr radical into Et isopropylmalonate under the usual conditions may be due to steric hindrance depending on the bulk of the groups about the central C atom or to the polar effect of the iso-Pr group.

C. J. WEST

Dehydration of citric acid and the technical preparation of anhydrous citric acid. FILIPPO PERCIABOSCO. *Atti III congresso naz. chim. pura applicata* 1930, 509–12.—Citric acid loses nearly all its water of crystn. at 70°. The loss is completed at 90° and decompn. begins at 130°. The anhyd. acid can be prepd. by either drying at 70–80° for 12 hrs. or by crystn. from solns. at approx. 100°.

E. G.-F.

The synthesis of agaric acid. MARIO PASSERINI AND GASTONE BANTI. *Atti III congresso naz. chim. pura applicata* 1930, 343–6.—In order to prove that agaric acid actually has the structure of 1-cetylcitric acid the following synthesis was accomplished: The mono-Na deriv. of $CO(CH_2CO_2Et)_2$ is treated with cetyl iodide: only a small portion of cetylacetonedicarboxylic acid ester could be isolated for identification. After hydrolysis from NaI the raw product was treated in ether with PhNC and AcOH (cf. *C. A.* 19, 822) in equimol. proportions and kept in the cold for 40 days. The condensation product was not isolated but was hydrolyzed with alc. KOH. The evolution of CO_2 is noticed upon acidifying and a ppt. is formed. The ppt. is treated with NaOH, Me heptadecyl ketone, m. 81–3°, remaining undissolved. The small sol. part is reppted with acid and washed with cold benzene. The benzene-sol. part, finally crystd. from MeOH, m. 33°, was identified as cetylmethylfumaric anhydride. The benzene-insol. part, recrystd. from water, m. 130–2°. It analyzed for cetylcitric acid with 1.5 mols water. It represents the *dl*-product.

E. GEBAUER-FUELNEGG

The oxime of carbonyl bromide. I. DE PAOLINI. *Atti accad. sci. Torino* (Classe

di sci. fis., mat., e mat.) **65**, 196–200(1930).—In a previous paper (*C. A.* **24**, 1632) it was mentioned that by the action of Br_2 on hydroxyglyoximecarboxylic acid, $HO_2C[C(:NOH)]_2OH$ a product was formed which was identical with that formed by the action of Br_2 on monohydroxyglyoxime, $H(C:NOH)_2OH$. This same product also results from similar reactions with oximinoacetic acid, $HC(:NOH)CO_2H$, and dihydroxytrioxime, $HO[C:NOH]_3OH$. The compd. is *carbonyl bromide oxime*, $Br_2C:NOH$. Its constitution is proved by the fact that this compd. also results from the action of Br_2 on fulminic acid: $CNOH + Br_2 \longrightarrow Br_2C:NOH$. It is best prepd. by the action of Br_2 on $HC(:NOH)CO_2H$ at 0°, CO_2 being evolved. Extd. with Et_2O and crystd. from petroleum ether, it m. 70.1°. It has a high vapor pressure even at low temps., the vapors being strongly irritant. The aq. soln. gives a red color with $FeCl_3$, green with $Cu(OAc)_2$. Treated in soln. with $Hg(NO_3)_2$ and distd. with steam, the dibromofuroxan is formed, $Br[(C_2N_2O)O]Br$. A. W. C

The structure of nitroamides and the points of view of Professor Hantzsch. A. Angeli. *Gazz. chim. ital.* **60**, 665–8(1930).—Several weaknesses in the arguments of Hantzsch (cf. *C. A.* **24**, 4001) are pointed out. C. C. Davis

Degradations in the sugar group. Venancio Deulofeu. *J. Chem. Soc.* 1930, 2602–7.—*d*-Arabinose oxime was converted into tetraacetylarabononitrile (**I**), which gives with Ag_2O after 36 hrs. at room temp. 40% of *d-erythrosediacetamide*, m. 210°; hydrolysis with H_2SO_4 gives *d*-erythrose. The production of triacetyl-*d*-erythrose by the action of Ag_2O on I and also of erythroseimine (Wohl, *Ber.* **32**, 3671(1889)) has been confirmed. Degradation of I by Zemplen's method (MeONa or $Ba(OH)_2$ and Ag_2CO_3) gave only a small amt. of erythrosazone (II). Tetraacetylxylononitrile treated in the same way, gave only small amts. of II. The sirup obtained by the action of MeONa, on oxidation with HNO_3, gives tartaric acid. *l*-Rhamnonoamide, m. 135°, with NaOCl, gives methylerythrose, isolated as the osazone. Degradation by Zemplen's methods gave small quantities of the same deriv. Pentaacetylgalactononitrile with MeONa gives 30% and with Ag_2CO_3 and $Ba(OH)_2$, 22% of lyxose. *Pentaacetylmannononitrile*, m. 94°, with Ag_2O, gives 32% of *d* arabinosediacetamide, m. 187°; Zemplen's methods give 61 and 56%, resp., of arabinose. Degradation of Ca mannonate gives only 23% by Ruff's method (H_2O_2 and $Fe(OAc)_2$). C. J. West

Glucose and the structure of the cycloses. A. L. Patterson. *Nature* **126**, 880 (1930).—A hypothesis is advanced to explain the fact that although there are 50 theoretically possible cycloses with 4, 5 or 6 hydroxyl groups, only 7 have been discovered in nature. An assumption that all the natural substances of this class originate from glucose and contain the configuration characteristic of that sugar, limits the no. of isomers to 14 and perhaps tends to explain the small no. which have been found in spite of the large vol. of work which would naturally lead to their discovery. R. C. H.

Reactive form of glucose oxime. M. L. Wolfrom and Alva Thompson. *J. Am. Chem. Soc.* **53**, 622–32(1931).—Aldehydoglucose pentaacetate (10 g.) in 100 cc. EtOH to which is added a mixt. of 2.3 g. $NH_2OH \cdot HCl$ and 5 g. AcOK in the dry form, gives 7.3 g. of the *oxime* (**I**), m. 99–9.5°, $[\alpha]_D^{24}$ 57.2° (0.2096 g. in 10.02 cc. MeOH); no rapid or appreciable mutarotation was observed in MeOH contg. 0.005% dry HCl. I (10 g.) 30 cc. Ac_2O and 60 cc. C_5H_5N at 0° give 8.9 g. of the *oxime hexaacetate* (**II**), m. 79°, then solidifies and m. 119.5°, $[\alpha]_D^{24}$ 41° (0.2029 g. in 10.06 cc. MeOH), $[\alpha]_D^{25}$ 45.9° (0.4022 g. in 10.06 cc. $CHCl_3$), does not show mutarotation. The lower-melting form is very unstable and changed spontaneously into the other, after which all attempts to obtain the 79° isomer failed; these are considered the *syn-* and *anti*-forms, although the possibility of an unstable pseudomorph is not excluded. II forms elongated prisms of the orthorhombic system, α 1.460, β 1.497, γ 1.504; other crystallographic data are given. β-Glucose oxime hexaacetate, prepd. according to Behrend (*C. A.* **1**, 2374), m. 113–5°, $[\alpha]_D^{25}$ 7.3° (0.4018 g. in 10.06 cc. $CHCl_3$), $[\alpha]_D^{24}$ —1.3° (0.4026 g. in 20 cc. MeOH); this is the ring form, corresponding in structure to glucose oxime; from the low rotation this is probably the β-isomer. *Mannonic acid nitrile pentaacetate*, from the oxime, Ac_2O and AcONa at 85–90°, m. 92–3°, $[\alpha]_D^{30}$ —1.1° (0.3525 g. in 10.06 cc. $CHCl_3$). Gluconic acid nitrile pentaacetate (**III**), m. 83–4°, $[\alpha]_D^{31}$ 48.3° (0.3505 g. in 10.02 cc. $CHCl_3$). β-Glucose oxime (**IV**), m. 142–3°, $[\alpha]_D^{25}$ —8.9°, final value —1.9° (1.0200 g. in 25 cc. H_2O). I and MeOH-NH_3 at 0° for 24 hrs. give **IV**. I at 200° begins to decomp.; only unchanged I was isolated from the partially decompd. product. II, heated at 135–40°, decomps. to III; the β-isomer did not form III on heating alone or with Ac_2O and AcONa. IV, Ac_2O and AcONa, heated at 75–80° for 1 hr., give mainly III but some II is also found, showing that the ring form of glucose oxime shifts to the

open-chain form on undergoing nitrile formation. AcOH and not H_2O is split off on nitrile formation from the oxime. C. J. WEST

Structure of carbohydrates and their optical rotatory power. I. General introduction. WALTER N. HAWORTH AND EDMUND L. HIRST. *J. Chem. Soc.* **1930**, 2615-35.—H. and H. discuss the validity of the "principle" of optical superposition, as proposed by Hudson (*C. A.* **24**, 2726), especially since optical rotations of sugars have usually been recorded for 1 solvent only and for light of one selected wave length. Hudson recognizes at least 2 categories of sugars, (a) those in which the additive principle seems to hold on the supposition of 1 general structure and (b) those in which different additive relationships seem to hold; H. and H. ask what exptl. justification has Hudson for suggesting that structural and not configurational differences are responsible for the lack of uniformity in the possible application of the principle of optical superposition to all the 6 common aldoses and confess that they find no such sanction in any of his writings. H. and H. point out (see part V) that where rotational values so remote from one another as 65° and —50° are given by 1 simple deriv. of mannose (in various solvents) any attempt to establish a fixed arithmetical or additive relation for the individual asym. centers of mannose derivs. will have a doubtful validity. H. and H. also criticize the nature of the structural proofs accepted by Hudson; they point out, *e. g.*, that he can provide no evidence for the 1,5-ring in any of the sugars to which he assigns it, except from the methylation data which he discards. A fundamental thesis in Hudson's recent scheme is the denial of structural identity to α- and β-mannose and to all their derivs.; this is based on differences in the sp. rotations in H_2O of α- and β-mannose and α- and β-glucose (47° as compared with 94°). However, when the rotations of tetramethyl-α- and β-methylmannosides are detd. in EtOH, the discrepancy of the mol. rotational differences disappears almost entirely and these 2 substances fall into line with the H_2O or EtOH values for several other methylated glucosides. A study of several pyranosides (1,5-ring) and furanosides (1,4-ring) shows that the glucosides preserve, in general, the same order of stability in their methylated forms and that, for glucosides of the same sugar, the furanoside form is much more easily hydrolyzed than the corresponding pyranoside form. When the true ring structures of α-Me glucoside and α-Me mannoside are compared, constancy of "epimeric differences" ceases to have any rational meaning. In commenting on Hudson's new formulas for di and polysaccharides, it is shown that a scheme of approx. accurate rotation values can be calcd. upon assumptions which are directly opposed in essential features to the structural views of Hudson. The elasticity of the methods of "proving" the ring structures of carbohydrates by rotational data is obvious. The rotational data of derivs. of 4-glucosido and 4-galactosidomannose are compared, and the ring structure of the 2 Me derivs. established by their cleavage with emulsin to the normal α-Me mannoside, which makes invalid Hudson's assumption that the α-mannose residue is the hypothetical variety for which he has calcd. the rotation to be $[\alpha]_D$ 77°. H. and H. conclude that the interpretation of the data on which they based the pyranose (1,5) structure of α-Me mannoside remains sound and receives further confirmation from these facts. **II. 4-Glucosido-α-mannose and its derivatives.** W. N. HAWORTH, E. L. HIRST, HARVEY RICHARD L. STREIGHT, HARRY A. THOMAS AND JOHN I. WEBB. *Ibid* 2636-44.—Details are given for the prepn. of cellobial (I). If the temp. rises to 30.5° during the reduction of heptaacetylcellobiosidyl bromide, there results *hexa-ac-2-deoxycellobiose*, m. 196°, $[\alpha]_D^?$ −15° ($CHCl_3$, *c* 1.5); it reduces boiling Fehling soln. and shows no unsatn. when tested with Br in $CHCl_3$. I with BzO_2H in MeOH-Et_2O gives *4-glucosido-α-methylmannoside* (II), m. 227-8°, $[\alpha]_D^{17}$ 46° (H_2O, *c* 1.0); hydrolysis with emulsin gives α-Me mannoside in 46% yield. I gives a *hepta-Ac deriv.* (III), m. 184°, $[\alpha]_D^{18}$ 30° ($CHCl_3$, *c* 1.0), 36° (Me_2CO, *c* 1.4), 21.5° (C_6H_6, *c* 1.5); deacetylation gives **II**. 4-Glucosido α-mannose was prepd from I and BzO_2H in Et_2O; it m. 175.6°, $[\alpha]_D^{18}$ 20° (H_2O, initial value), 12.5° (equil. value); in reducing power 155% of the sugar are equiv. to 1 g. of glucose. The rate of mutarotation is of the same order as that of α-mannose but rather slower. The value of $[\alpha]_D^{18}$ —1° was calcd. for the 4-glucosido-β-mannose. Octaacetyl-4-glucosido-α-mannose was transformed into heptaacetyl-4-glucosido-α-mannosidyl bromide, which gives **III** with Ag_2CO_3 in MeOH; quinoline gives the same compd. The mol. rotational difference of the α- and β-forms of the biose is similar to that of the α- and β-forms of mannose itself, although it was the supposed anomaly of this difference which led Hudson to ascribe different ring structures to the 2 mannoses. **III. 4-Galactosido-α-mannose and its derivatives.** W. N. HAWORTH, E. L. HIRST, MILLICENT M. T. PLANT AND REGINALD J. WM REYNOLDS. *Ibid* 2644-53.—The following results furnish a proof of the presence

of the ordinary α-mannoside residue in derivs. of 4-galactosido-α-mannose and demonstrate that the 1,4-ring structure cannot apply to the normal α-Me mannoside; these results are diametrically opposed to the contention of Hudson. Lactose was converted through its acetobromo deriv. into lactal, m. 191–2°, $[\alpha]_D^{23}$ 27.5° (H_2O, *c* 1.6); BzO_2H in MeOH-EtOH gives *4-galactosido-α-methylmannoside* (I), m. 207°, $[\alpha]_D^{19}$ 66° (H_2O, *c* 0.7); Ac_2O and AcONa or Ac_2O and C_5H_5N give the *hepta-Ac deriv.*, which could not be crystd., $[\alpha]_D^{18}$ 36° ($CHCl_3$, *c* 1.5), $[\alpha]_D^{28}$ 19° (C_6H_6, *c* 1.6). Hydrolysis of I by emulsin gives α-Me mannopyranoside and galactose, for which a method of sepn. is given; Lactal and BzO_2H in Et_2O give 70% of *4-galactosido-α-mannose* (II), crystg. with 1 mol. H_2O, m. 150–60°, $[\alpha]_D^{20}$ 38° (H_2O, initial), 27° (equil. value); in reducing power 162 parts of II are equiv. to 100 parts of glucose; the rate of mutarotation is of the same order as that of α-mannose. The rotation of the β-form of 4-galactosidomannose is calcd. to be $[\alpha]_D$ 16° in 76% EtOH, which is about that given by Bergmann. IV. Derivatives of α- and β-methyl mannopyranoside. HAROLD G. BOTT, W. N. HAWORTH, E. L. HIRST AND ROBERT S. TIPSON. *Ibid* 2653–9.—Contrary to Hudson (*C. A.* **24**, 2726), mannose (I) undergoes condensation by heating with 2% MeOH-HCl with the formation of both the α- and β-forms of Me mannopyranoside (II); 10 g. I and 95 cc. MeOH-HCl were boiled 1 hr. and kept at —10° for several hrs.; 6.1 g. α-II crystallizes out; after removing the acid with $PbCO_3$, the resulting gum is acetylated with C_5H_5N and Ac_2O, giving 3.7 of the tetra-Ac deriv. of β-II, m. 161°, $[\alpha]_D^{18}$ —46.8°; excess of Me_2NH in MeOH, heated 4 hrs. at 100°, gives *β-Me mannopyranoside* (III), yellow glass, $[\alpha]_D^{21}$ —66° (H_2O, *c* 1.05); 0.5 *N* NaOH gives the same product The rate of hydrolysis of III in 0.01 *N* HCl at 100° is very slow; $[\alpha]_D^{20}$ —64° (initial) changes to —59°, —55°, —50° and —46° after 2, 4, 7 and 10 hrs., resp.; even with 0.1 *N* HCl 15 hrs. were required for complete hydrolysis, 15° (final value). III, or the tetra-Ac deriv., with Me_2SO_4, Me_2CO and aq. NaOH gives the *tetra-Me deriv.* (IV), $b_{0.08}$ 90°, $b_{0.1}$ 110–2°, m. 36–7°, n_D^{17} 1.4535 (supercooled), $[\alpha]_D^{20}$ —79° (MeOH, *c* 0.52), —80° (H_2O, *c* 1.0), —87° ($CHCl_3$, *c* 0.46), —72° (C_6H_6, *c* 0.7), —82° (EtOH, *c* 0.4); the equil. rotation in 1% MeOH-HCl is 60°. Hydrolysis gives tetramethylmannopyranose, identified as the anilide. Methylation of I with Me_2SO_4 and 30% aq. NaOH and finally with Ag_2O and MeI gives a mixt. of the α- and β-forms of IV, contg. 32% of the β-form. Simultaneous deacetylation and methylation of tetraacetyl-α-methylmannopyranoside give almost quant. tetramethyl-α-methylmannopyranoside, also obtained by methylation of α-Me mannopyranoside. Thus, the normal forms of α- and β-Me mannoside give rise on methylation and hydrolysis to one and the same tetramethylmannose and this yields the tetramethyl-δ-mannonolactone, which has been shown to undergo epimerization to tetramethylgluconolactone. The rotations for tetramethylmethylmannopyranoside are (α- and β-forms): H_2O, 43°, —80°; $CHCl_3$, 57°, —87°; EtOH, 75.5°, —82.5°; C_6H_6, 77°, —72°. Although the discrepancy in mol. rotation values, noted by Hudson, is shown in H_2O, it almost disappears when the rotations are taken in EtOH. V. Optical rotatory powers of methylated lactones derived from the simple sugars. W. N. HAWORTH, E. L. HIRST AND JAMES A. B SMITH. *Ibid* 2659–63.—Those sugars which have *cis*-HO groups situated on the 2nd and 3rd C atoms, *viz.*, mannose, lyxose and rhamnose, display rotational relationships different from those observed with glucose, galactose or xylose. Since Hudson holds the view that these rotational divergences have their origin in differences in ring structure and not in configurational effects, it was important to obtain definite information concerning the presence or absence of such effects in cases where both the structure and the configuration of the substance under consideration have been established beyond doubt. With H_2O, $CHCl_3$, Et_2O and C_6H_6, resp., as solvents, the following results were obtained: *Mannose series.*—δ-Mannono-(*d*) 150, 59.5, 35, 20; γ-mannono-(*d*) 65, —10, —36, —50; δ-lyxono-(*d*) 35.5, —60, —87, —102; γ-lyxono-(*d*) 82.5, —28, —70, —70; δ-rhamnono-(*l*) —130, —68, —39, —15; γ-rhamnono-(*l*) —56.5, 13, 65, 87. *Glucose series.*—δ-Glucono-(*d*) 98, 103, 123, 121; γ-glucono-(*d*) 62, 42, 67, 68; δ-xylono-(*d*) 0, 9, 12, 17; γ-xylono-(*d*) 88, 81, 84, 106. *Galactose series.*—δ-Galactono (*d*) 153, 101, 96, 128; γ-galactono-(*d*) —34, —13, —11, —11; δ-arabono-(*l*) 181, 125, 105, 166; γ-arabono-(*l*) —44, —9, —3, 16. These results indicate that *cis*-MeO groups, when present in the mol., have a profound influence on the optical rotatory powers of substances which cannot alter their ring structure under the influence of solvents; it is thus clearly impossible to say with any degree of security that configurational effects play no part in the anomalous rotations of α-mannose and its derivs.

C. J. WEST

Ring structure of mannose. The optical rotation of 4-glucoside-α-mannose. HORACE S. ISBELL. *Bur. Standards J. Research* 5, 1179–87; *Proc. Nat. Acad. Sci.* 16, 704–7(1930).—4-Glucosido-α-mannose monohydrate was prepd. by the method of Brauns and its properties redetd.; $[\alpha]_D^{20}$ initial 14.7°, final 5.7°. The mutarotation approximated the monomol. course, $k_1 + k_2 = 0.016$ at 20°. A comparison of the initial mol. rotation with that of β-cellobiose gave an epimeric difference of 16,900. This agrees approx. with the value (14,900) obtained from the pair α-*d*-glucose (113) and α-*d*-mannose (30) and that (15,300) from the pair α-Me *d*-glucoside (157.9) and α-Me *d*-mannoside (79) but deviates from that predicted by Hudson (6700) (*C. A.* 24, 2726) who considers that the members of these pairs of monosaccharides have different rings while the disaccharides should have the same ring since the 1,4-linking is excluded in their case. The epimeric difference calcd. from the rotations of 4-galactosido-β-mannose and -lactose is approx. 5130 which agrees fairly well with the value obtained (6480) from the rotations of the pair β-*d*-glucose (19) and β-*d*-mannose (−17). Thus it appears that the derivs. of α-mannose and α-glucose parallel one another throughout while the derivs. of β-mannose and β-glucose also parallel one another, but no decision between the rival ring classifications of Hudson (*loc. cit.*) and Haworth (Constitution of Sugars, London, 1929) can be derived. An improved method for deacetylation with $Ba(OMe)_2$ in abs. MeOH is given. R. C. HOCKETT

New crystalline calcium chloride compound of α-*d*-gulose and its rotation and mutarotation in aqueous solution. HORACE S. ISBELL. *Bur. Standards J. Research* 5, 711–55(1930); cf. *C. A.* 24, 2726.—Pure gulose has never been crystd. but its rotation has been detd. by means of the cryst. $CaCl_2$ addn. compd. ($C_6H_{12}O_6 . CaCl_2 . H_2O$) (I) (cf. *C. A.* 23, 4932). The latter exhibits mutarotation and gives $[\alpha]_D^{20}$ extrapolated initial 37.7°, at equil. −15.4° + 0.78 *C*, where *C* is the concn. of the compd. in g. per 100 cc., $k_1 + k_2 = 0.0193$ at 20°. When the $CaCl_2$ is removed from a freshly prepd. soln. of I by means of dry $(CO_2Ag)_2$ the resulting soln. of pure α-*d*-gulose (II) shows a rate of mutarotation ($k_1 + k_2 = 0.0206$) close to that of I and near to that of mannose. The mol. rotation of II is 11,100 which differs very little from the value of 11,650 for I. The equil. rotation of II in the absence of $CaCl_2$ is not appreciably altered by small changes in the concn. of sugar, but that of I is greatly altered by small changes in concn. Concd. solns. of I on diln. with water exhibit a mutarotation rate approx. equal to that of II, showing that the salt changes the equil. rotation of *d*-gulose by altering the relative amts. of the different forms of the sugar in soln. R. C. HOCKETT

Synthesis of a methoxyketose. ERIC FRANK HERSANT AND WILFRID H. LINNELL. *Nature* 126, 844(1930).—A *5-methoxyketohexose* was prepd. by condensing $CO(CH_2OH)_2$ with *α-methoxyglyceric aldehyde* (I) in 5% aq. soln. contg. 0.25% of $Ba(OH)_2$ for 3 weeks at room temp. I was prepd. by methylation of *α-chloro-β-hydroxypropiondiethylacetal* with NaOMe to give *α-methoxy-β-hydroxypropiondiethylacetal*, b_6 100–2°, which was hydrolyzed with dil. mineral acid to I. The condensation products were converted into osazones, and fractionated from AcOEt into a product m. 183° and one m. 130°. The former was converted through the osone to a ketose, m. 80–5°, which analyzed correctly for a monomethoxyketohexose. It required 48 hrs. to condense with MeOH to *monomethoxymethylketoside*, thus confirming the supposition that because of the position of the MeO group it cannot be a γ-form which would condense in 1 hr. On complete methylation to *tetramethoxymethylketoside*, the product behaved like a normal fructose deriv. toward alk. $KMnO_4$ and was converted by hydrolysis with 3% aq. HCl for 3 hrs., to a cryst. *tetramethoxyketose*, m. 95–6°, which did not depress the m. p. of an authentic specimen of tetramethoxyfructose. HNO_3 oxidation of the product m. 130° gave *trimethyllactol acid* which was converted by alk. $KMnO_4$ to a *trimethylarabonolactone*, identical in its behavior on hydrolysis with the lactone from normal fructose but not with that from tetramethoxyl-γ-fructose. H. and L. conclude that the evident identity of the synthetic ketose derivs. in which a 5-atom ring is impossible with derivs. of normal fructose excludes the furanose constitutions for the latter and lends support to the accepted pyranose constitutions. R. C. HOCKETT

Individualities of anhydrofructose and difructose anhydride. R. F. JACKSON AND S. VAN GORGEN. *Bur. Standards J. Research* 5, 733–4(1930); cf. *C. A.* 23, 4452–3.—The cryst. anhydrofructose described by Irvine and Stevenson (*C. A.* 23, 3907(1929)) simultaneously with the description of difructose anhydride by J. and G. is not the same compd. as the latter. The former compd. is deliquescent, $[\alpha]_D^{26}$ 30.17°, m. 143–5° (acetate, $[\alpha]_D^{20}$ 1.5°, m. 123°), mol. wt. 162, and it crystallizes in transparent spheroids. The latter is not deliquescent, $[\alpha]_D^{20}$ 27.0°, m. 162–4° (acetate, $[\alpha]_D^{26}$ 0.5°, m. 137° (sinters 125°)), mol. wt. 307, and it crystallizes in laminated spheres. R. C. H.

Polysaccharides. XLIII. Effect of heating polysaccharides in glycerol. P. KARRER AND E. v. KRAUSS. *Helv. Chim. Acta* **13**, 1071–3(1930); cf. *C. A.* **24**, 1538.—Acetylated starch (44.7% Ac) when heated in glycerol at 200–20° for several hrs. gives a product (I) contg. 7–10% Ac. This shows that hydrolytic processes occur which may affect glucosidic linkages. Cu nos. of the partially deacetylated compds. vary about 2. Yields were not quant. and the stronger reducing portions remain in the mother liquor after pptn. with alc. I which dialyzes quickly and completely through collodium membranes is like starch (II) in regard to its behavior with AcBr by means of which it is degraded to acetobromomaltose and then to hepta-acetylmaltose (III) in yields about the same as that obtained from II. These results are similar to those obtained by Pictet and Vogel (*C. A.* **73**, 4676) by heating II in glycerol, in which isotrihexosan (IV) was formed. IV, dextrinosan (obtained by heating II with glycerol at 240°), and dextrinose (V) (obtained by the action of $H_2C_2O_4$ or malt diastase on IV) were degraded with AcBr. The first 2 gave yields of III, about the same as that from II, but with V the yield was less. These substances, therefore, are most correctly viewed as partially hydrolytically attacked but not yet profoundly changed starch. **XLIV. Chitin.** P. KARRER AND S. M. WHITE. *Ibid* 1105–13.—As reported previously (*C. A.* **23**, 2478) reacetylated chitosan (I) is degraded to acetylglucosamine by chitinase (snail ferment) (II). It is shown now that *formyl-*, *propionyl*, *butyryl*, and *benzoychitosan* are not affected by II, showing this ferment to be sp. for I. *α-Naphthalenesulfonyl deriv.* of I and the foregoing derivs. are prepd. by standard procedures. The type of union of N in chitin and I is discussed in the light of various publications and some new information is presented but results do not allow a definite conclusion. Methylation expts. argue against primary amino groups since a quaternary salt could not be obtained. On the other hand, I and $PhSO_2Cl$ give *N benzenesulfonyl chitosan* which is difficultly sol. in H_2O and easily sol. in dil. alkali. *Monomethylchitosan* and $PhSO_2Cl$ give a *N deriv.* insol. in dil alkali. The chem. behavior of I and its derivs. in many respects is similar to those of glucosamine-glucosides. The N (8%) of I can be split off quantitatively by the van Slyke method, on the basis of which I still contains 12% Ac which cannot be bound to N. FREDERICK C. HAHN

Constant occurrence of non-reducing disaccharides in hydrolyzed inulin. RICHARD F. JACKSON AND EMMA MCDONALD. *Bur. Standards J. Research* **5**, 1151–60(1930); cf. *C. A.* **23**, 4452.—Pure inulin (I) extd. from wild chicory, dandelion, golden rod, burdock and Jerusalem artichoke yields on hydrolysis with H_2SO_4 approx. 91% fructose, 3.7% glucose and 5.3% of non-reducing difructoses regardless of source. The same compn. was previously found for I from dahlia tubers (*loc. cit.*). Eleven-fold recrystn. of dahlia I with rejection of the mother liquors has no appreciable effect upon its compn. Related polysaccharides do not give these difructoses so that the latter cannot be considered by-products of the hydrolysis. They appear, therefore, to be an integral part of the I mol. Expts. as yet incomplete indicate that at least 3 disaccharides are present in the mixt. If the isomerism is due to the process of hydrolysis and only 1 such group is present in a mol. of I, the min. possible mol. wt. becomes 6000 while if all 3 groups which appear as non-reducing disaccharides on hydrolysis are present in 1 mol., the mol. wt. of I must be at least 18,000. This is greater than that usually claimed but closest to the f. p. value of Tanret (*Bull. soc. chim.*, 227, 622(1893)) who gave 4827. R. C. HOCKETT

Reactions of heterocycles with phenols. The reaction of ethylene oxide with phenol. RICHARD A. SMITH AND JOSEPH B. NIEDERL. *J. Am. Chem. Soc.* **53**, 806–8(1931).—$(CH_2)_2O$ and PhOH with concd H_2SO_4 in the cold give 65% of *o*-vinylphenol (I), b_{10} 56°, b_{15} 77°, m. 29–9.5° (cor.); $O{:}C_6H_4{:}O$ is a good inhibitor to polymerization. This was further identified by the prepn. of the tetra-Br deriv., m. 105°, and *o*-vinylphenoxyacetic acid, m. 137°. Heating PhOH and $(CH_2)_2O$ 6 hrs. at 150° gives $HOCH_2CH_2OPh$ (II), b_{80} 163–7°; 0.2 mol. concd. H_2SO_4 with this ether for 1 week gives I. It is assumed that $(CH_2)_2O$ and H_2SO_4 first form $HOCH_2CH_2OSO_2OH$, which then reacts with PhOH to give II, which then splits off H_2O to give I. C. J. WEST

Preparation of *o*-chlorotoluene from *p*-toluenesulfonyl chloride. L. MCMASTER AND J. CAROL. *Ind. Eng. Chem.* **23**, 218–9(1931).—Chlorination of *p*-$MeC_6H_4SO_2Cl$ in the presence of $SbCl_3$ at 70–80° and subsequent hydrolysis of the 3,4-$ClMeC_6H_3SO_2Cl$ with 10% H_2SO_4 to 3,4-$ClMeC_6H_3SO_3H$ and further hydrolysis of the latter with 80% H_2SO_4 and superheated steam gave *o*-ClC_6H_4Me in 90% yield. RACHEL BROWN

Derivatives of 3-amino-4-methoxytoluene. L. CHAS. RAIFORD AND OLIVER GROSZ. *Proc. Iowa Acad. Sci.* **36**, 268(1929).—This product, known technically as cresidine, was first obtained by Hofmann and Miller [*Ber.* **14**, 573(1881)]. Before the present work, however, only 2 substitution products had been obtained from it, *viz.*, the 6-nitro

and the 6-Cl derivs. In this work a mono-Br deriv. has been prepd. and its structure established. It readily forms a quaternary NH_4I, therefore the Br atom does not occupy position 2, adjacent to the amino group, as this would hinder the formation of such a salt. 3,5,4-$Br_2(MeO)C_6H_2Me$ was synthesized and found to be different from the di-Br deriv. obtained from the compd. in question by replacement of the amino group by Br. This leaves the structure of the mono-Br deriv. as *3-amino-4-methoxy-6-bromotoluene*. The new Br compd. was characterized by the prepn. of the *N-Ac* and *N-Bz derivs.* and *3-acetylamino-4-methoxy-6-bromobenzoic acid*.

W. G. GAESSLER

The effects of substituents in the formation of thiocarbanilides. L. CHAS. RAIFORD AND G. MERVIN MCNULTY. *Proc. Iowa Acad. Sci.* **36**, 269(1929).—It is well known that many reactions of C_6H_6 derivs. are hindered by the presence of substituents that are ortho as respects the reacting group. In the work here reported such hindrance has been observed when the substituent occupies the *m*-position. *p*-$H_2NC_6H_4NHAc$ reacts very readily with CS_2 in alc., forming the corresponding thiocarbanilide. When a Me radical is meta to the amino group the reaction velocity is decreased by about ½. If one or both *m*-positions are occupied by Br atoms, the reaction is completely prevented. A single Br atom in the *o*-position caused inhibition, also. This reaction was studied with the following compds.: 2,4- and 3,4-$Br(NH_2)C_6H_3NHAc$, 2,6,4- and 3,5,4-$Br_2(H_2N)C_6H_2NHAc$. The Ac groups of the above-mentioned thiocarbanilides cannot be removed from these compds. by any method of hydrolysis tried in this work without, at the same time, decompg. the ureas.

W. G. GAESSLER

4-*p*-Tolylthiosemicarbazide and its reactions with ketones. R. W. BOST AND W. F. SMITH. *J. Am. Chem. Soc.* **53**, 652–4(1931).—4-*p*-Tolylthiosemicarbazide was obtained in 90% yield from *p*-MeC_6H_4NCS and $N_2H_4 \cdot H_2O$ in EtOH; it m. 137°; *HCl salt*, m. 173°. Condensation products were prepd. as follows: *acetone*, m. 142°; *Me Et ketone*, m. 75°; *acetylacetone* (I), m. 100°; *Et acetoacetate*, m. 107°, *cyclohexanone*, m. 125°, *acetophenone*, m. 165°; *benzophenone*, pale yellow, m. 158°; *benzoylacetone*, pale yellow, m. 126°; *benzoin*, cream, m. 161°; *benzil*, cream, m. 164°; *carvone*, cream, m. 147°. Refluxing I in abs. EtOH 1 hr. gives a mixt. of 3,5-dimethylpyrazole and *p*-tolylthiourethan.

C. J. WEST

Condensation products of methylolamines with phenolic ethers. LYDIA MONTI WITH GUGLIELMO VERONA. *Gazz. chim. ital.* **60**, 777–86(1930). In continuation of earlier expts. on condensation products of methylol acid amides and many aromatic compds. (cf. *C. A.* **24**, 4013), the same reaction was utilized to prep. directly some hydroxyalkylbenzylamines from multivalent phenolic ethers and methylol acid amides. Einhorn has already described a similar condensation reaction with *p*-$O_2NC_6H_4OEt$ and β-$C_{10}H_7OMe$ (cf. *Ann.* **343**, 288(1905); *C. A.* **2**, 2682), and consequently a corresponding reaction was to be expected with other multivalent phenolic ethers. By carrying out the reaction with equimol. proportions of phenolic ether and methylol acid amide there was formed in some cases, besides the benzylamine derivs., derivs. of xylylenediamines by condensation of 2 mols. of methylol acid amide with 1 mol. of phenolic ether. Sapon. of these products, both in acid and in alk. medium, yields the corresponding amines, which were characterized by HCl salts and picrates. Thus prepd., the methoxybenzylamines are of special interest because of their constitutional relation to certain natural alkaloids. Methylolchloroacetamide (I) and methylolbenzamide (II) were prepd. according to the directions of Einhorn (cf. *Ann.* **343**, 223, 282(1905)). Veratrole (2.2 g.), I (2 g.), glacial AcOH (25 cc.) and fused $ZnCl_2$ (5 g.), heated until completely dissolved, let stand 48 hrs., poured into water, extd. with boiling CCl_4, the ext. evapd. and the residue recrystd. from CCl_4, yield 3,4-$(MeO)_2C_6H_3CH_2NHCOCH_2Cl$ (III), m. 116.8° (cf. 117–7.5° of Jacobs and Heidelberger, *C. A.* **9**, 1612). The residue from the extn. with CCl_4, crystd. from water and AcOH, yield 3,4,1,6-$(MeO)_2C_6H_2(CH_2NHCOCH_2Cl)_2$ (IV), m. 169–70°. III (2 g.), refluxed with 20% HCl (50 cc.), evapd. to a very small vol., the cryst. residue dried on a porous plate and washed with Et_2O, yields *3,4-dimethoxybenzylamine-HCl* (V), blackens 240°, m. 246° (decompn.). Satd. aq. picric acid (VI), added to aq. V and the ppt. recrystd. from water, yields the picrate, $(C_9H_{13}O_2N).C_6H_2(NO_2)_3OH$, lemon-yellow, m. 169–70° (same m. p. as that reported by Douetteau, *C. A.* **6**, 605, for a prepn. by another method). IV, boiled with 20% HCl as with III (*loc. cit.*), yields *3,4-dimethoxyxylylenediamine-HCl* (VII), not, however, in a form pure enough to be analyzed. Concd. aq. VI and aq. VII yield, after recrystn. of the ppt. from boiling water, the *picrate*, $C_{10}H_{16}O_2N_2.(C_6H_2(NO_2)_3OH)_2.2H_2O$, orange-yellow, loses its H_2O of crystn. at 100–20° (becomes lemon-yellow), m. 216–8° (decompn.). 2,3,4-$C_6H_3(OMe)_3$ (2.7 g.), I (2 g.), glacial AcOH (25 cc.) and $ZnCl_2$ (4 g.), heated until the latter is dissolved, let stand 2 days, poured

into water and the ppt. recrystd. from boiling water, yield *2,3,4-trimethoxychloroacetylbenzylamine* (VIII), m. 98–9°, insol. in cold. aq. alkalies, sol. in hot, dil. acids and in cold concd. acids. VIII (2 g.) and 20% HCl, refluxed 2 hrs., filtered and the filtrate evapd. to a relatively small vol., yield a deliquescent mass of *2,3,4-trimethoxybenzylamine-HCl* (IX). Attempts to obtain the free base (X) by neutralizing IX with alkali gave a reddish yellow oil with disagreeable odor and an alk. reaction. Neither did NH_4OH liberate the base from IX. Aq. IX and satd. aq. VI yield, after recrystn. of the ppt. from boiling water, the *picrate* of X, $C_{10}H_{15}O_3N.C_6H_2(NO_2)_3OH$, golden yellow, begins to alter at 205°, m. 208–10° (decompn.). *Chloroplatinate* of X, yellow, blackens around 200°, does not m. up to 300°. 1,2,3-$C_6H_3(OMe)_3$ (XI) (5 g.) in AcOH, II (4.5 g.) in AcOH and $ZnCl_2$ (10 g.), heated until the latter is dissolved, let stand 24 hrs., poured into cold water and the paste recrystd. from boiling C_6H_6, yield a fraction, m. 172–5°, and a fraction, m. 120–5°. The 1st fraction recrystd. repeatedly from dil. AcOH (with animal charcoal) yields *2,3,4-trimethoxydibenzoylxylylenediamine*, $(MeO)_3C_6H(CH_2NHBz)_2$ (XII), silky, m. 189–90°. The 2nd fraction, recrystd. from dil. AcOH, yields *2,3,4-trimethoxybenzoylbenzylamine*, 2,3,4-$(MeO)_3C_6H_2CH_2NHCOBz$ (XIII), lustrous, m. 125–6°. If, in the condensation of II and XI, the reaction mixt. is refluxed 2–3 hrs. or if H_2SO_4 is used instead of $ZnCl_2$, only XII is formed. XII and XIII are insol. in aq. alkalies, but are sol. in cold. concd. acids. Unlike III and IV, XII and XIII do not react when refluxed with 20% HCl. They can, however, be sapond with alc. KOH. XIII (5 g.) and 30% alc. KOH (40 cc.), refluxed 6–8 hrs., the EtOH eliminated, the residue dild. with water, extd. with Et_2O, yield a yellow oil identical with that from VIII. Under similar conditions XII yield a reddish yellow oil, probably *2,3,4-trimethoxyxylylenediamine*. Treated with satd. aq. IV, it ppts. the *picrate*, $C_{11}H_{16}O_2N_2.(C_6H_2(NO_2)_3OH)_2$, which, recrystd. from boiling water, is golden yellow, m. 215.5°. I (2 g.), 1,3,4-$C_6H_3(OMe)_3$ (2.6 g.) and $ZnCl_2$ (4 g.), refluxed until the latter is dissolved, the soln. (dark blue with violet fluorescence) let stand 48 hrs., poured into water and the ppt. purified with animal charcoal and recrystn. from CCl_4, yield *2,4,5-trimethoxychloroacetylbenzylamine* (XIV), m. 115–6°, insol. in aq. alkalies and cold, dil. acids. XIV (2 g.) and 20% HCl (50 cc.), refluxed 2 hrs., yield *2,4,5-trimethoxybenzylamine-HCl*, 2,4,5-$(MeO)_3C_6H_2CH_2NH_2$, does not liberate the base with NH_4OH, but in concd. aq. soln. and satd. aq. IV it ppts. the *picrate*, $C_{10}H_{15}O_3N.C_6H_2(NO_2)_3OH$, which recrystd. from boiling water, is orange-red and m. 200–2°. 3,4,5-$(MeO)_3C_6H_2CO_2H$ (XV) (3.5 g.), I (2 g.) in glacial AcOH (25 cc.) and $ZnCl_2$ (5 g.), refluxed until dissolved, let stand 3 days, poured into water and the ppt. purified by washing with boiling C_6H_6 (to remove XV) and recrystg. from water contg. AcOH, yields *3,4,5-trimethoxy-2-chloroacetylbenzylamine-o-carboxylic acid*, 2,3,4,5-$ClH_2CCONHCH_2(MeO)_3C_6HCO_2H$ (XVI), m. 189–90°. XVI, sapond. as before, and the crude product purified by evapg. the acid soln. to a very small vol., drying the cryst. mass on a porous plate and washing with Et_2O, yields *3,4,5-trimethoxy-2-benzylamine-o-carboxylic acid-HCl*, 2,3,4,5-$ClH_2NCH_2(MeO)_3C_6HCO_2H$, m. 153–4° (decompn.); its concd. aq. soln. and satd. aq. IV give the *picrate*, intense yellow, m. 150–2°. C. C. Davis

Decomposition of benzenediazonium sulfate by aliphatic alcohols. Herbert H. Hodgson and Arnold Kershaw. *J. Chem. Soc.* 1930, 2784–5.—PhN_2HSO_4 is decompd. by the aliphatic alc., giving either an ether and C_6H_6 or C_6H_6 and an aldehyde, ether formation greatly predominating; the data given show decreasing formation of C_6H_6 from $PhCH_2OH$ to BuOH, MeOH being an exception. The results, expressed as mol. % aldehyde on mol. amt. of sulfate taken, are: $PhCH_2OH$, 19.7; MeOH, unweighable; EtOH, 9.5; PrOH, 4.7; iso-PrOH, 4.8 (with H_2O, 3.6); BuOH, 1.3. C. J. West

The action of acids on diazoaminobenzene. II. J. C. Earl. *Proc. Roy. Soc. N. S. Wales* **64**, 96–100(1930); cf. *C. A.* **24**, 2115.—Further expts. have led to the isolation and identification of I, the substance formed when very dil. alc. HCl acts on diazoaminobenzene (II), as *benzenediazoaminoazobenzene*, $PhN_2C_6H_4NHN_2Ph$, and its formation can be detected in any of the reactions which effect the conversion of II into aminoazobenzene (III). It is suggested that the formation of I by means of AcOH is an essential intermediate stage in the conversion of II into III as follows: (a) $2PhN_2NHPh \longrightarrow PhN_2C_6H_4NHN_2Ph + PhNH_2$; (b) $PhN_2C_6H_4NHN_2Ph + PhNH_2 \longrightarrow PhN_2C_6H_4NH_2 + PhNHN_2Ph$. Further work on this mechanism will be the subject of a later communication. When 7.5 g. powd. II was kept in 90 cc. cold AcOH at 14° for 20 min., then poured with stirring into a large excess of ice water, allowed to stand in an ice bath for 45 min., filtered, the ppt. washed, dissolved in hot alc. contg. a little NH_3, a small quantity of water added and cooled, 0.7 g. of impure I sepd.;

repeated recrystn. gave pure I, m. 119.5°. Mixts. of I and II show a remarkable resistance to sepn. by crystn. from either aq. alc. or petr. ether. N. A. LANGE

Group influence on the colors of substituted benzeneazophenols, including *o*-azophenols. HERBERT HENRY HODGSON AND WOLF ROSENBERG. *J. Soc. Chem. Ind.* 49, 405–8T(1930); cf. *C. A.* **24**, 2735.—Differences between isomeric 2- and 4-hydroxyazobenzenes, and the influence of NO_2, SO_3H, Cl, Br, I and Me groups either in the primary or in the secondary dye component are discussed from the standpoint of the theories of Lapworth and Robinson and of Ingold. K. H. ENGEL

Diarylacylhydrazine series. II. Salt formation in the benzidine and semidine rearrangements. JOHN J. RITTER AND FRANK O. RITTER. *J. Am. Chem. Soc.* 53, 670–6(1931); cf. *C. A.* **24**, 4001.—The monoacetylhydrazines previously described, on oxidation with $K_2Cr_2O_7$, fall in 2 classes; the *N*-Ac derivs. give the corresponding azo compds., while the *N'*-derivs. give brilliant, intensely colored red or violet solns. from which highly colored cryst. products may be isolated. The production of the colored oxidation products appears to depend upon the presence of the group PhNH- and is undoubtedly caused by air oxidation of the original unrearranged products. The oxidation of the hydrazo compds. in the presence of HCl was found to be quite parallel to the oxidation of their Ac derivs. with $K_2Cr_2O_7$; this behavior is most readily explained by assuming that the hydrazo compds. in acid soln. form mono salts, which may involve the N or N' atom, and oxidize to new colored substances on the one hand, or to the azo compds., on the other, depending on the N atom involved in the salt formation. Consideration of the rearrangement of 78 hydrazo compds. indicates that when salt formation takes place on a N atom attached to an aryl nucleus in which the *p*-position is open, diphenyloids result, while semidines are formed when the salt in question involves a N atom attached to a nucleus carrying a *p*-substituent. The following new compds. are reported: *p-Acetoxyhydrazobenzene*, m. 117–8° (all m. ps. cor.); *N-acetyl-p-iodohydrazobenzene*, m. 135–6°; *N'-ac deriv.*, m. 156–7°; *N-acetyl-p-carboxyhydrazobenzene*, m. 207–8°; *N'-acetylbenzenehydrazo-p-phenetole*, m. 108°, by reduction of benzeneazo-*p*-phenetole with Zn and glacial AcOH; *N-acetyl-p-acetoxyhydrazobenzene*, m. 105–6°. C. J. WEST

***p*-Cymene studies. XIV. 2-*p*-Cymylhydrazine.** ALVIN S. WHEELER AND THOS. L. KING. *J. Am. Chem. Soc.* **53**, 809–10(1931); cf. *C. A.* **23**, 5470.—The following salts of *p*-cymylhydrazine-2 have been prepd.: *acetate*, m. 63–4°; *lactate*, m. 134.5°; *oxalate*, m. 167°; *benzoate*, m. 72–5°; only the lactate is stable with H_2O. *m-Nitrobenzaldehyde 2-p-cymylhydrazone*, rich red (yellow by transmitted light), m. 143°, stable toward H_2O. Unstable products were obtained with various other CO-contg. compds., reddish, viscous oils, do not crystallize at —30°. This hydrazine is not a good reagent for the CO group. C. J. WEST

Derivatives of phenylboric acid, their preparation and action upon bacteria. WM. SPAMAN AND JOHN R. JOHNSON. *J. Am. Chem. Soc.* **53**, 711–23(1930).—Me borate, purified by washing with cold concd. H_2SO_4, b_{750} 67–7.8°, d_4^{20} 0.932, n_D^{24} 1.3558. Addn. of PhMgBr to Me borate in Et_2O gives 30% of $PhB(OH)_2$, m. 215.5–9° (preheated bath) 221° (cor., block). Nitration with fuming HNO_3 at —15° to —9° gives 70% of the *m*-NO_2 deriv. and 10% of the *o*-NO_2 deriv. The *m*-NO_2 deriv. m. 275–6.5° (preheated bath to 250°), 273° (cor.), 319° (cor., block); dried to constant wt., it m. 287.6° (cor.), probably that of the anhydride, $O_2NC_6H_4BO$; the structure was established by the formation of *m*-$BrC_6H_4NO_2$ by the action of $HgCl_2$ and Br. Fuming HNO_3 added slowly to $PhB(OH)_2$ in Ac_2O at —15° gives 60% of the *o*-NO_2 *deriv.*, yellow, m. 139.2–40.8° (cor.) in a bath heated from 20°, 138.7–9.2° in a bath preheated to 120°, m. 147.5° (block); dried to constant wt., the anhydride m. 143.5–7.7° (cor.); there also results about 2% of the *p*-NO_2 *deriv.*, yellow, m. 305° (decompn.), did not m. 360° (block). Reduction with $Fe(OH)_2$ gives 44–8% of *m-aminophenylboric acid*, m. 92.8–3.8° (cor.), m. 176° (cor., block); the anhydride m. 193° (cor.); *Ac deriv.*, m. 274.5° (cor.); *Bz deriv.*, m. 290° (cor.). *Benzoyl-o-aminophenylboric acid*, m. 283.4° (cor.), 319.5° (cor., block). Bacteriological tests showed that $PhB(OH)_2$ and the 3 NO_2 derivs. exert a bacteriostatic effect upon *Staphylococcus aureus;* the *m*-NH_2 deriv. and its derivs. do not produce this effect. The NO_2 derivs. are more highly bacteriostatic than $PhB(OH)_2$, which in turn is much more effective than H_3BO_3. Although no direct comparison was made, it appears that the *m*-NO_2 deriv. (1:200) approaches or slightly surpasses PhOH (1:70) in its bactericidal action toward *B. typhosus* but $PhB(OH)_2$ (1:200) is much weaker than PhOH. C. J. WEST

II. **Aromatic arsenic compounds containing sulfur groups attached to the nucleus. Thiocyano and disulfido groups.** HARRY J. BARBER. *J. Chem. Soc.* **1930**, 2725–9;

cf. *C. A.* **25**, 92.—4-$H_2NC_6H_4AsO_3H_2$, diazotized and treated with CuSCN and KSCN, gives 30% of *4-thiocyanophenylarsonic acid*, prisms; boiling with 2 *N* NaOH gives an amorphous product, which is oxidized by I-KI in $NaHCO_3$ to diphenyl disulfide-4,4'-diarsonic acid. The *2-thiocyano deriv.* is comparatively unstable and on mild oxidation gives the *2,2'-diarsonic acid*, also obtained from 2-sulfinophenylarsenious oxide (I) with SO_2 and HI, followed by oxidation; *N* NaOH hydrolyzes the disulfide to thiol or thioarsenite. *3-Nitro-4-thiocyanophenylarsonic acid*, yellow leaflets (50% yield), boiling with 2 *N* NaOH gives NH_3; after acidification, SO_2 is liberated and a brown tarry mass results. I in glacial AcOH and $H_4P_2O_6$ contg. KI, boiled 5 min., gives the *compd.* $C_6H_4\langle^{As:As}_{S\quad S}\rangle C_6H_4$, lemon-yellow, m. 177-8°; this was also obtained with other strong reducing agents; it is unaffected by boiling alkali but concd. H_2SO_4 gives a yellow-orange soln.; it is slowly oxidized by I in $NaHCO_3$ suspension, giving the disulfide arsonic acid; concd. HNO_3 rapidly oxidizes it to 2-sulfophenylarsonic acid; heating at 300° produces a complex decompn.; heating with Cu bronze did not give thianthrene. C. J. West

Action of trichloromethyl chlorocarbonate upon phenols. N. N. Melnikov. *J. prakt. Chem.* **128**, 233-8(1930); cf. *C. A.* **24**, 5725.—$Cl_3COCOCl$ (I) (30 g.) and 16.2 g. *p*-MeC_6H_4OH in 75 cc. 2 *N* NaOH give 16 g. *p-tolyl trichloromethyl carbonate* (II), b_{10} 162°, m. 47°; with 10.9 g. *p*-MeC_6H_4OH and 5 g. I, there results di-*p*-tolyl carbonate, m. 114°. I (20 g.) and 14.4 g. *β*-$C_{10}H_7OH$ give 18 g. of the *β-naphthyl deriv.* (III), m. 128°, while 14.4 g. *β*-$C_{10}H_7OH$ and 5 g. I give 10 g. di-*β*-naphthyl carbonate, m. 175°. *p-Chlorophenyl deriv.* (IV), m. 109°; *p-nitrophenyl deriv.* (V), pale yellow, m. 132°. II and $PhNH_2$ in Et_2O give *p*-$MeC_6H_4OCONHPh$, m. 114°; III gives *β*-$C_{10}H_7OCONHPh$, m. 154°; IV gives *p*-$ClC_6H_4OCONHPh$, m. 137-8°; V gives *p*-$O_2NC_6H_4OCONHPh$, m. 147°. The use of NaOH gives larger yields and purer products than with KOH, since normal carbonates are also formed with KOH. Also in *J. Russ. Phys.-Chem. Soc.* **62**, 1671-5(1930). C. J. West

Formation of aromatic thiosulfonic acids from disulfides. Ernest W. McClelland and Leonard A. Warren. *J. Chem. Soc.* 1930, 2690-3.—2,2'-*o,o'*-Dithiodiphenyl-4,5-dihydroglyoxaline with SO_2 gives a product (*C. A.* **24**, 1376) which is now represented as a *thiosulfonic acid* (I, R = SO_3H), since KCN yields the *thiocyanate* (I, R = CN), m. 180°; the same product was obtained when the HBr salt of II in hot H_2O is mixed with aq. KCN and cooled. The thiosulfonic acid is also obtained from I (R = H) and SO_2 in boiling EtOH; decompn. gives the disulfide. *2-Phenyl 4,5-dihydroglyoxaline-m-thiosulfonic acid*, pale yellow, m. 246° (decompn.); the *p*-isomer m. 248° (decompn.); KCN gives the *p-thiocyanate*, yellow, m. 265°. The following disulfides, dissolved or suspended in EtOH, were recovered unchanged after prolonged treatment with SO_2: di-*p*-tolyl disulfide, 3,4,3',4'-tetramethoxy-, 5,5'-dibromo-3,4,3',4'-tetramethoxy-, 4,4'-dinitro- and 2,5,2',5'-tetrabromo-diphenyl disulfides, di-2-naphthol-1-disulfide and dibenzyl disulfide.

The synthesis of aromatic hydroxy ketones. I. *o*- and *p*-Acylphenols with normal C_4 to C_9 chains. G. Sandulesco and A. Girard. *Bull. soc. chim.* [4], **47**, 1309-14 (1930). *o*- and *p*-Acylphenols, HOC_6H_4COR, were prepd. with the object of studying their hypnotic properties in comparison with that of 1,2-$HOC_6H_4CO_2H$, the relationship between soly. in the lipoids and hypnotic activity was also of interest. The method of prepn. was as follows: PhOH was energetically mixed with finely divided $AlCl_3$ (1 mol.) and heated to 100° (1 mol. of HCl is evolved); 1 mol. of RCOCl was then added and heated to 125-30° for 1 hr. The Al complex was decompd. with water, and the oil was sepd., washed and fractionated. The yields of the *o*- and *p*-isomers were 45-60 and 30-40%, resp.; the total yield was 80-90%. The *o*-compds. are differentiated from their isomers by the soly. of the former in Et_2O, insoly. in alkali, greater difficulty in their reduction and lower m. and b. ps. Due to the insoly. in alkali, all attempts to prep. the ether derivs. of the *o*-compds. failed. The compds. prepd. and their properties were as follows (d. at 24°, *n* at 25.3°): ***o*-Butyrylphenol** (yield 45%), b_8 119°, m. 10.5-0.6°, d. 1.0683, *n* 1.5375 (***semicarbazone***, m. 192-3°); ***p*-butyrylphenol** (yield 50%), b_{10} 130°, d. 1.0435, *n* 1.5309 (***semicarbazone***, m. 204-5°); ***p*-valerylphenol** (yield 29%), b_{10} 197.5-8.5°, m. 63° (***benzoate***, m. 92°); ***o*-caproylphenol** (yield 50%), b_{10} 142-3°, m. 17.2-7.4°, d. 1.0260, *n* 1.5254 (***semicarbazone***, m. 179°); ***p*-caproylphenol**

(yield 34%), b_{10} 207–8°, m. 61° (*benzoate*, m. 105.5°); *o-heptoylphenol* (yield 48%), b_{10} 155–6°, m. 9.8°, d. 1.0110, *n* 1.5209 (*semicarbazone*, m. 162°); *p-heptoylphenol* (yield 41%), b_9 214°, m. 91–1.5° (*benzoate*, m. 96.5–7.0); *o-octoylphenol* (yield 45%), b_{11} 169–70°, m. 22.3°, d. 0.9989, *n* 1.5169 (*semicarbazone*, m. 157–8°); *p-octoylphenol* (yield 38%), b_{10} 224–5°, m. 62° (*benzoate*, m. 107–8°); *o-nonoylphenol* (yield 55%), b_{10} 180°, m. 18.4°, d. 0.9887, *n* 1.5139 (*semicarbazone*, m. 164°); *p-nonoylphenol* (yield 35%), b_{10} 232°, m. 54.5° (*benzoate*, m. 99.8–100°). The ketophenols were reduced to alkylphenols with Zn-Hg. In the *p*-series a yield of 75–90% was obtained. In the *o*-series the reduction was accomplished in a mixt. of 50% by vol. each of HOAc and fuming HCl, with yields of about 80%. The consts. were as follows: (d. at 23°, *n* at 25.5°, *n* of benzoates at 45.6°, Ac = $PhOCH_2CO_2H$ deriv.). *o-Butylphenol* (yield 83%), b_{10} 109.5–110°, d. 0.9774, *n* 1.5180 (*Ac* m. 105.5°); *p-butylphenol* (yield 86%), b_{11} 125–6°, m. 22°, *n* 1.5165 (*benzoate*, m. 27°, *n* 1.5082); *o-amylphenol* (yield 72%), b_{11} 122–4°, d. 0.9635, *n* 1.5132 (*Ac* m. 77–7.5°); *p-amylphenol* (yield 79%), b_{10} 134–6°, m. 23°, *n* 1.5119 (*benzoate*, m. 51–1.5°, *n* 1.5038); *o-hexylphenol* (yield 80%), b_{10} 135–6°, m. −2°, d. 0.9524, *n* 1.5089 (*Ac* m. 89.5–90°); *p-hexylphenol* (yield 77%), b_{10} 146–7°, m. 28° (*benzoate*, m. 26.5°, *n* 1.4996); *o-heptylphenol* (yield 90%), b_{10} 147–8°, m. 2–3°, d. 0.9432, *n* 1.5058 (*Ac* m. 71.5°); *p-heptylphenol* (yield 73%), b_9 157°, m. 26° (*benzoate*, m. 40.5–41°, *n* 1.4969); *o-octylphenol* (yield 79%), b_{11} 160–2°, m. 18–18.5°, d. 0.9362, *n* 1.5029 (*Ac* m. 88–8.5°); *p-octylphenol* (yield 85%), b_{10} 169°, m. 41–2° (*benzoate*, m. 40.5°, *n* 1.4938); *o-nonylphenol* (yield 85%), b_{13} 176–7°, m. 19–20°, d. 0.9309, *n* 1.5005 (*Ac* m. 75.5°), *p-nonylphenol* (yield 80%), b_{10} 180–1°, m. 42.5° (*benzoate*, m. 36.2°, *n* 1.4920). I. M. LEVINE

Catechol of the cacao bean. W. B. ADAM, F. HARDY AND M. NIERENSTEIN. *J. Am. Chem. Soc.* **53**, 727–8(1931). - The catechol of the cacao bean is identical with 1 of the 3 catechols present in the heartwood of the cutch-producing acacias, *viz.*, *l*-catechol. Both m. at 229° and have $[\alpha]_D$ −69° (H_2O); the penta-Ac deriv. m. 151° and has $[\alpha]_D$ −12 ($C_2H_2Cl_4$). C. J. WEST

New type of oxidation product derived from quinones. W. H. HUNTER AND MURRAY M. SPRUNG. *J. Am. Chem. Soc.* **53**, 700–11(1931).—Oxidation of 3,4,5,2,6-$Br(MeO)_2C_6OH$ (I) in 900 cc. 50% AcOH at 80° with 6.6 g. CrO_3 for 15–20 min., filtering from the phenoxyquinone and pouring into 1200 cc. cold H_2O gives about 32% of a colorless *compd.* **IIa** or **IIb** (R = 3,4,5,2,6-$Br_3(MeO)_2C_6$), $C_{28}H_{18}O_{15}Br_6$, m. 206–7° (bath heated to 200°, decompn.); oxidized very slowly by hot alk. $KMnO_4$, hot acid $KMnO_4$ and boiling concd. HNO_3. Boiling $AgNO_3$ in 95% EtOH produces only a slight murkiness. Dilg. a soln. in concd. H_2SO_4 gives **I**. I (1.2 g.) with AcCl and 2 drops concd. H_2SO_4 gives 1.1 g. of the *Ac deriv.*, $C_{16}H_{12}O_9Br_4$, m. 141–4° (decompn.); this is derived from the monomeric form of the acid; with 6% KOH there results **I**. Hydrolysis of **II** with 6% KOH gives 63.2% **I**; the filtrate contains the Br ion. Hydrolysis could also be effected by NH_4OH or $PhNH_2$. Oxidation of 3,5-dibromo-6-methoxy-2-(3,4,5-tribromo-2,6-dimethoxyphenoxy)-*p*-benzoquinone with CrO_3 also gives II. Oxidation of 3,4,5,2,6-$Cl_3(MeO)_2C_6OH$ (**III**) gives the *compd.* (**IV**, R′ = 3,4,5,2,6-$Cl_3(MeO)_2C_6$), $C_{14}H_{10}O_8Cl_4$, m. 187.4–7.8° (decompn.); the substance is inert to most common chem. reagents; diln. of a soln. in concd. H_2SO_4 gives **III**. The *Ac deriv.*, $C_{16}H_{12}O_9Cl_4$, m. 135–6° (decompn.). **IV** is also obtained by the oxidation of chlorinated phenoxyquinones. The mechanism of the formation of these oxidation products is discussed, leading to the following possible structures:

$$RO_2CCOC(OMe):CBrCO_2C(CO_2R).C(OMe):CBr.CO.O$$

IIa. Ester of Br analog of **IV** (keto form)

$$O[C(CO_2R).C(OMe):CBr.CO.O]_2$$

IIb. Ether of Br analog of **IV**

$$HOC(CO_2R').C(OMe):CCl.CO.O$$

(**IV**)

C. J. WEST

The occurrence of 2,6-dimethoxyquinone in Adonis vernalis L. WALTER KARRER. *Helv. Chim. Acta* **13**, 1424–8(1930).—O:C C(OMe):CH C(:O) CH:COMe (I) in an av. yield of 1.3 g. can be extd. from 200 g. of *Herba adonidis vernalis*. It is thought by K. that I exists as such in the living plant and is not a decompn. product. It is one of the very few derivs. of $C_6H_4O_2$ found in plants. I. M. LEVINE

Nitration of certain substituted benzaldehydes and the stability of the aldehyde group. HERBERT H. HODGSON AND ERNEST W. SMITH. *J. Soc. Chem. Ind.* **49**, 408–10T (1930). Further nitration of 3-$O_2NC_6H_4CHO$ could not be effected without simul-

taneous oxidation of the CHO group. Anils (Schiff's bases) could be nitrated only in the aniline nucleus. *3-Nitrobenzal-2'-methylanil*, m. 73–5°, treated with fuming HNO_3 and then hydrolyzed, gave the unchanged aldehyde and nitrotoluidines. *3-Nitrobenzal-2':5'-dichloroanil*, m. 103°, reacted similarly. $3,4\text{-}O_2N(AcNH)C_6H_3CH(OAc)_2$, in Ac_2O resisted nitration. $4\text{-}MeOC_6H_4CHO$ in concd. H_2SO_4 gave the $3,4\text{-}O_2N(MeO)C_6H_3CHO$ (I) of correct m. p. (86°). On further nitration of I in concd. H_2SO_4 the CHO group was replaced, $2,4,6\text{-}(O_2N)_3C_6H_2OMe$ being obtained. On adding I to fuming HNO_3 $2,4\text{-}(O_2N)_2C_6H_3CHO$, m. 87°, resulted. $4\text{-}EtOC_6H_4CHO$ gave *3-nitro-4-ethoxybenzaldehyde* (II), m. 62°. On further treatment with fuming HNO_3, II yielded $2,4,6\text{-}(O_2N)_3C_6H_2OEt$, m. 79°. $4\text{-}ClC_6H_4CHO$ gave *4-chloro-3-nitrobenzaldehyde*, m. 62°. Continued treatment with HNO_3 simply oxidized this compd. to *4-chloro-3-nitrobenzoic acid*, m. 181–2°. $4\text{-}BrC_6H_4CHO$ gave $4,3\text{-}Br(O_2N)C_6H_3CHO$ m. 103°, which, on further nitration, yielded *4-bromo-3,5-dinitrobenzaldehyde*, m. 126° $2\text{-}MeOC_6H_4CHO$ gave a good yield of *5-nitro-2-methoxybenzaldehyde*, m. 89°.

K. H. ENGEL

Aldehydes. III. Synthesis of simple and of substituted alkylcinnamic aldehydes. MARSTON T. BOGERT AND GARFIELD POWELL. *Am. Perfumer* **25**, 617–9, 620(1930); cf. *C. A.* **24**, 1932.—In the present paper the following new aldehydes of the usual Perkin synthesis type are recorded: *Bis(α-ethylcinnamylidene)acetone*, m. 104–5°; *α,p-dimethylcinnamic aldehyde*, m. 128.5–30.5°; *α-ethyl-p-methylcinnamic aldehyde*, b_{10} 137.5°; *α-o-anisalpropionaldehyde* (*o-methoxy-α-methylcinnamic aldehyde*), $b_{4.25}$ 128°; *α-o-anisalbutyraldehyde* (*o-methoxy-α-ethylcinnamic aldehyde*), m. 48.2–8.7°, $b_{5.5}$ 140° (*oxime*, m. 126–9°; the *phenylhydrazone* gave positive reaction for the Knorr pyrazoline test and yields a condensation product with AcMe); *α-piperonylidenepropionaldehyde*, b_6 150–5° (*oxime*, m. 124–5°; *phenylhydrazone*, yellow, m. 121–3°); *α-piperonylidenebutyraldehyde*, yellowish, m. 56–7°, b_4 155–60° (*oxime*, m. 141–3°; *phenylhydrazone*, yellowish, m. 118–20°); *α-piperonylideneënanthaldehyde*, yellow, m. 85–7°, b_2 165–7°. The foregoing aldehydes are yellowish in color.

W. O. E.

Chemistry of lignin. V. Distillation of alkali lignin with zinc dust in an atmosphere of hydrogen. MAX PHILLIPS. *J. Am. Chem. Soc.* **53**, 768–74(1931); cf. *C. A.* **24**, 1353.—Alkali lignin from corn cobs, distd. with Zn in a H atm. gives an aq. portion, contg. MeOH, Me_2CO, an acid (detd. as AcOH) to the extent of 1.48, 0.36 and 0.24%, resp. (calcd. on the basis of the wt. of lignin used), and catechol, and an oil (16% of the wt. of the lignin used), 55% of which was alkali-sol., in which guaiacol was definitely identified; a phenol contg. the MeO group and yielding a 3,5-dinitro benzoyl deriv., m. 110°, was also obtained but not further identified. The isolation of catechol and guaiacol as degradation products of lignin is believed to lend support to the hypothesis that lignin contains an aromatic nucleus. The evolution of CO_2 in the Zn distn. of lignin in a H atm. indicates that, in all probability, the lignin mol. contains at least 1 C atom directly united to 2 O atoms. This may indicate the presence of either a CO_2H group, free or esterified, or a lactone group in the lignin mol.

C. J. WEST

The decomposition of dibenzoyl peroxide by ultra-violet light. FR. FICHTER AND A. SCHNIDER. *Helv. chim. Acta* **13**, 1428–33(1930).—Bz_2O_2 in a quartz tube was subjected to the action of ultra-violet light from a Hg lamp. From the portion decompd. a yield of about 80% of the theoretical quantity of CO_2 and Ph_2 was obtained. The residue, an amorphous resin, was not characterized.

I. M. L.

Preparation of benzamide. C. H. KAO AND SHAO-YÜAN MA. *J. Chem. Soc.* 1930, 2788.—BzOH (200 g.), 180 g. $(NH_4)_2CO_3$ and 300 cc. 95% AcOH, heated gradually to boiling and then distd. so that not more than 100 cc. passed over in 1 hr., until the temp. at the head of the column was 150°, and the residue poured into 2 vols. of cold H_2O and neutralized with NH_4OH, gave 96–8 g. $BzNH_2$; about half of the BzOH was recovered.

C. J. WEST

The Hoesch-Houben synthesis in the preparation of aromatic ketimines and hydroxyphenylimino esters. EVA BRESSON AND J. B. CULBERTSON. *Proc. Iowa Acad. Sci.* **36**, 266(1929).—This synthesis involves the condensation of a phenol with a nitrile (aliphatic or aromatic). It is effected by the passage of dry HCl through their soln. in anhyd. ether, with or without the addn. of dry $ZnCl_2$. Anhyd. $AlCl_3$ was substituted for $ZnCl_2$ in some cases. In the present study PhCN was employed in every case with the following phenols and phenol ethers: phenol, the 3 cresols, quinol, catechol, pyrogallol, carvacrol, resorcinol mono- and di-Me ethers. With phenol, the 3 cresols, catechol, pyrogallol and carvacrol, no definite condensation products could be isolated. Quinol gave a double compd. of $p\text{-}HOC_6H_4OC(:NH)Ph$ with $ZnCl_2$;

without $ZnCl_2$ the free *p*-$HOC_6H_4OC(:NH)Ph$ was obtained. *m*-HOC_6H_4OMe gave free $HO(MeO)C_6H_3C(:NH)Ph$ when $AlCl_3$ was employed and an addn. compd. with $ZnCl_2$. W. G. GAESSLER

The synthesis of 4-hydroxy- and 2-hydroxydiphenyl ketimines. PAUL VITTUM, RICHARD ANDERSON AND J. B. CULBERTSON. *Proc. Iowa Acad. Sci.* **36**, 266–7(1929).—These syntheses were carried out through the action of the corresponding HO-nitrile upon PhMgBr in anhyd. ether. Over 2 equivs. of the Grignard reagent were employed, one to react with the phenol group and the other with the nitrile. The addn. compd. was decompd. with water and NH_4Cl at about —15°. The ketimine extd. with ether was pptd. as the HCl salt by the addn. of dry HCl. The hydroxy nitriles were prepd. from the corresponding hydroxy aldehydes by the action of Ac_2O on their oximes. Some modifications were worked out in the prepn. of the oximes and the nitriles. W. G. GAESSLER

Configuration of norvaline. P. KARRER AND H. SCHNEIDER. *Helv. Chim. Acta* **13**, 1281–91(1930).—Cryst. *brucine d(−)-allylhippurate* (I) (103 g.) was prepd. by cooling a mixt. of 75.3 g. allylhippuric acid, 75.3 cc. 5 *N* NaOH, 160.3 g. brucine, 75.3 cc. 5 *N* HCl, and 250 cc. H_2O which had previously been heated on the water bath and filtered. Recrystd. from water I gave $[\alpha]_D^{20}$ —40.9°. The Et_2O ext. of I treated with HCl gave cryst. *d(−)-allylhippuric acid* (II), m. 89°, $[\alpha]_D^{20}$ —32.11°. From the mother liquor of II *l(+)-allylhippuric acid* (III), m. 90°, was obtained, $[\alpha]_D^{18}$ +32.9°. 1.0228 g. III, 9cc. *N* KOH, 1.15 g. $KMnO_4$ in 40 cc. H_2O, and 1.4 cc. concd. H_2SO_4 warmed, filtered and concd. *in vacuo* gave 9.36 g. cryst. *l(+)-benzoylaspartic acid*, m. 176°, $[\alpha]_D^{19}$ +22.4°. Some racemization had occurred. *d(−)-Benzoylaspartic acid*, prepd. similarly from II, m. 175°. *dl-Benzoylaspartic acid* (IV) was prepd. in the same way from *dl*-allylhippuric acid. Oxidation with $KMnO_4$ or O_3 gave IV as a monohydrate sintering 70°, m. 119°. III in *N* KOH reduced by H_2 in the presence of Pt gave the hydrate of *l(+)-benzoylnorvaline*, m. 64°, which, dried over P_2O_5, gave *l(+)-benzoylnorvaline*, m. 95°, $[\alpha]_D^{?}$ 14.0°. *d(−)-Benzoylnorvaline* (V), m. 97°, $[\alpha]_D^{19}$ —13.1°, was similarly prepd. from II. *d(−)-Norvaline* (VI), $[\alpha]_D^{19}$ —21.84°, was prepd. by splitting the brucine salt of *dl*-formylnorvaline. The Et esters of VI and VII were prepd. with EtOH and dry HCl in 59% yield. VII in C_5H_5N with BzCl gave *Et d(+)-benzoylnorvaline* (VIII), m. 59°, $[\alpha]_D^{19}$ 7.98°. VIII in alc. NaOH gave the hydrate of V, m. 64° which dried to V, m. 93°, $[\alpha]_D^{19}$ —15.0°. RACHEL BROWN

Structure of the compounds produced by the addition of mercuric salts to olefins. II. ESTHER GRIFFITH AND C. S. MARVEL. *J. Am. Chem. Soc.* **53**, 789–92(1931); cf. C. A. 20, 1986.—In the 1st paper only 2 optically active isomers were isolated although 4 were theoretically possible; in the present work only 2 isomers were obtained and characterized. *l-Menthylamide* of *cinnamic acid*, m. 158–9°, $[\alpha]_D^{25}$ —82.9° (MeOH); 47% yield; $Hg(OAc)_2$ gives an unstable compd. unsuitable for fractional crystn. *d-* and *l-octyl cinnamates*, b_6 174–7° and b_6 175–80°, $[\alpha]_D^{30}$ 42.4° and $[\alpha]_D^{27}$ —43.3°, resp.; the yields were 73 and 50%; the addn. products with $Hg(OAc)_2$ were low-melting compds.; the Br compds. were also unsatisfactory for fractional crystn. *d-Bornyl cinnamate*, b_{6-7} 200–2°, $[\alpha]_D^{27}$ 32.8° (MeOH), 32.3° (AcOEt). $Hg(OAc)_2$ in MeOH gives *d-bornyl β-methoxy-α-acetoxymercurihydrocinnamate*, a mixt. m. 90–100°, which could not be sepd. by crystn. The *α-Br deriv.*, obtained from the Ac deriv. with NaBr, was resolved into 2 isomers, m. 131–2°, $[\alpha]_D^{25}$ 17.3°, and m. 147–8°, $[\alpha]_D^{25}$ 14.9°. C. J. WEST

3-Chloro-*o*-toluic acid and its conversion into 3-chloro-α-hydroxyphthalide. LEOPOLD F. LEVY AND HENRY STEPHEN. *J. Chem. Soc.* **1930**, 2788.—*3-Chloro-o-toluic acid*, m. 91.5°, was prepd. from the $3\text{-}NH_2$ deriv. through the Sandmeyer reaction. The molten acid, treated with Br and then warmed with dil. NaOH, gives *3-chloro-α-hydroxyphthalide*, m. 138°. C. J. WEST

Stability of magnesium *dl*-mandelate. ALEXANDER FINDLAY AND ALAN N. CAMPBELL. *J. Chem. Soc.* **1930**, 2721–4; cf. *C. A.* **22**, 3632.—The soly. of Mg *l*- and *dl*-mandelates is given at 5° intervals from 0 to 40°; the soly. of the *l*-salt gives a simple curve, rapidly ascending at temps. above 30°; the solid phase is the anhyd. salt. The *dl*-salt gives a 3-branched soly. curve, indicating the existence of 2 hydrates, with 1 H_2O, stable up to about 12°, and with 0.5 H_2O, stable between 12–29°; above 29° the salt is anhyd. Data are given for the *vapor pressure* of the hydrates. Mg *dl*-mandelate exists as stable solid phase throughout the temp. range investigated; the system is complicated by the existence of hydrates and it is practically impossible to deduce the temp. of the

transition point for the active antipodes and the racemate; the presumption is that the point lies at a fairly low temp. C. J. WEST

Syntheses of glucosides. VI. Preparation of β-glucosides of phenols. ALEXANDER ROBERTSON AND ROY B. WATERS. *J. Chem. Soc.* 1930, 2729–33.—Dry "active" Ag_2O (5 g.), added to a paste of 1 g. PhOH, 9 g. *O*-tetraacetyl-α-glucosidyl bromide and 10 cc. quinoline, agitated 15 min. and kept in a desiccator for 1 hr., the filtered AcOH soln. poured into H_2O and crystd. from EtOH, gives 3.5 g. of the tetraacetate, m. 128°, of β-Ph glucoside, m. 176°; in the same way, 4 g. β-$C_{10}H_7OH$ gives 13 g. of the tetra-Ac deriv., m. 135°, of β-2-naphthyl glucoside, m. 188°, $[\alpha]_D^{20}$ —26.7° (in 95% Me_2CO) *m*-$C_6H_4(OH)_2$ (1 g.) gives 4 g. of *O-octaacetyl-β-m-phenylenediglucoside*, m. 203°, $[\alpha]_D^{20}$ —83.1° (in Me_2CO). *O-Monobenzoylquinol*, m. 161°, gives the *tetraacetylglucoside* of *quinol monobenzoate*, m. 154–5°, $[\alpha]_D^{20}$ —63.97° (Me_2CO); hydrolysis with MeOH-NH gives 70% of arbutin. Helicin and *O*-tetraacetyl-β-glucovanillin were similarly prepd. C. J. WEST

New constituent of the ethereal oil from the wood of Chamaecyparis obtusa. I. GAKUJI TAKAHASHI, YASO YOSHIKI AND TOKUZO YAGINUMA. *Proc. Imp. Acad.* (Japan) 6, 393–6(1930).—Two new substances have been isolated from the ethereal oil extd. from the wood tar of *Chamaecyparis obtusa* Sieb and Zucc. and sepd. mechanically. The 1st compd., $C_{20}H_{32}O_2$, m. 236°, rhombic, bisphenoidal, *a:b:c* = 1.6684:1:0.6367 (polarization microscope), 1.6605:1:0.6360 (Goldschmidt reflection goniometer), α 1.5975, β 1.6004, γ 1.6185, V 26° 35′. The 2nd compd., $C_{23}H_{22}O_7$, d_4^{23} 1.337, m. 64°, rhombic, bisphenoidal, *a:b:c* = 0.7115:1:0.6237(P), 0.7107:1:0.6292(G), α 1.5743, β 1.5946, γ 1.6401, V 34° 37′; 2 mols. Br give the *compd.* $C_{23}H_{20}O_7Br_2$, m. 134–5°, d_4^{3} 1.664, rhombic, bisphenoidal, *a:b:c* = 1.1461:1:0.4716, α 1.6442, β 1.6533, γ 1.6691, V 37° 34′; excess Br gives a *compd.* $C_{14}H_{16}O_4Br_2$, m. 117°, rhombic, *a:b:c* = 0.6367:1:1, α 1.5145, β 1.5777, γ 1.978, V 25° 50′. C. J. WEST

Higher terpene compounds. XLII. Dehydration and isomerization of agathicdicarboxylic acid. L. RUZICKA AND J. R. HOSKING. *Helv. Chim. Acta* 13, 1402–23 (1930); cf. *C. A.* 23, 3711.—Agathicdicarboxylic acid, $C_{20}H_{30}O_4$ (I), a dibasic, dicyclic acid derived from Hartmanila copal, was further characterized by its destructive dehydrogenation and isomerization products. Dehydrogenation was brought about by heating with Se for 42 hrs. at 290–340°. The products, isolated as the picrates, consisted of 1,5,6-$C_{10}H_5Me_3$ (II), 1,7-dimethylphenanthrene (III), a *compd.* $C_{17}H_{20}$ (IV) of unknown structure, and an unknown compd. (V), the picrate of which m. 210°. II was synthesized starting from *o*-$MeC_6H_4CH_2CH_2OH$ through the compds. $MeC_6H_4CH_2CH_2Br$, b_{20} 120°, $MeC_6H_4CH_2CH_2CMe(CO_2Et)_2$, b_{16} 192–3° (in 50% yield, with $NaCMe(CO_2Et)_2$), $MeC_6H_4CH_2CH_2CHMeCO_2H$, b_{16} 179–80° (by hydrolysis), $MeC_6H_4CH_2CH_2CHMeCOCl$ (VI), b_{16} 146–7°, (with $SOCl_2$), *1,6-dimethyl-5-keto-5,6,7,8-tetrahydronaphthalene* (VII), b_{16} 153–5°, m. 41–2° (*semicarbazone*, m. 194–5°) (from 6 g. of VI in petroleum ether boiled with 5 g. of $AlCl_3$, in a 90% yield), *1,5,6-trimethyl-7,8-dihydronaphthalene* (VIII), b_{11} 130–1°, d_4^{20} 0.9760, n_D^{20} 1.5672, M_D calcd. 55.97, found 57.63 (from VII and MgMeI, and distn. of the products over Na). Dehydrogenation of VIII with Se yielded II, b_{11} 147–8°, m. 31–2°, d_4^{22} 1.0103, n_D^{22} 1.6093, M_D calc. 55.50, found 58.32 (*picrate*, m. 137–8°, *styphnate* (addn. compd. with trinitroresorcinol), m. 131°). Oxidation of II (2.8 g.) with $K_3Fe(CN)_6$ yielded the corresponding *tribasic acid* (2.2 g.), m. 90–1°. IV, $b_{0.8}$ 138–9°, m. 36–7°, d_4^{16} 1.027, d_4^{70} 0.992, n_D^{16} 1.6056, n_D^{70} 1.5847, M_D calcd 73.50 and 71.77 for 6 and 5 double bonds, resp., found 75.25 and 75.67 at 16° and 70°, resp. picrate, m. 138–9°; *styphnate*, m. 153–4°. Catalytic hydrogenation of IV in HOAc in the presence of PtO yielded $C_{17}H_{24}$ (IX). Se had no effect on IV alone or on IX. A *ketodibasic acid*, $C_{16}H_{12}O_5$, m. 304–5° (decompn.) (*di-Me ester*, $b_{0.8}$ 165–70°, m. 155–6°, *oxime*, m. 240°), is obtained when IV is oxidized with $K_3Fe(CN)_6$ and KOH. Upon oxidation of III, m. 85–6° (*picrate*, m. 132–3°; *styphnate*, m. 159°), with CrO_3, a *quinone*, m. 166°, is obtained. Dehydrogenation of I can also be brought about by heating with S, giving smaller yields of II and III but no IV or V. The tetrahydro deriv. of I yields II, IV and V but not a trace of III, when it is dehydrogenated with Se. Heating I with 95% HCO_2H at 120–30° produces its isomer, *isoagathic acid*, $C_{20}H_{30}O_4$ (X), m. 287–8°, $[\alpha]_D$ 12.84°; *di-Me ester* (7.9 g. from 9 g. of X and MeI through the Ag salt), m. 121–2°, $[\alpha]_D$ 6.09°; *di-Et ester*, m. 102–3°, $[\alpha]_D$ 9.67°, d_4^{111} 1.014, d_4^{104} 1.018 (calcd.), n_D^{104} 1.483, M_D calcd. 109.27, found 108.96. Catalytic hydrogenation of X at 60° yields the *dihydro deriv.*, $C_{20}H_{32}O_4$, m. 308–10°, $[\alpha]_D$ 16.03°, *di-Me ester*, m. 110–1°, $[\alpha]_D$ 9.11°, d_4^{131} 1.027, d_4^{120} 1.033 (calcd.), n_D^{120} 1.477, M_D calcd. 100.50, found 99.72. Similar to

the behavior of **I, X** undergoes decompn. when heated above its m. p., evolving CO_2 and yielding *isonoragathic acid*, $C_{19}H_{30}O_2$ (**XI**), m. 177–8°, $b_{0.2}$ 181–2°, $[\alpha]_D$ 2.13°; *di-Me ester*, m. 98–9°, $[\alpha]_D$ 2.65°, d_4^{112} 0.978, d_4^{102} 0.985 (calcd.), n_D^{102} 1.4864, M_D calcd. 89.14, found 88.80. By reduction, **XI** takes up 1 mol. of H_2 to yield the *dihydro acid*, $C_{20}H_{34}O_2$, which could not be crystd.; the *Me ester* of this compd. m. 80–1°, $[\alpha]_D$ 35.34°, d_4^{111} 0.9714, d_4^{102} 0.9767 (calcd.), n_D^{102} 1.4793, M_D calcd. 89.61, found 88.97. Dehydrogenation of **X** with Se yields **III** and an *unknown compd.*, the picrate of which m. 164°. No trace of **II** or **IV** was found. The conclusions that may be drawn from the work are: (1) **I** is a bicyclic compd. having one double bond in the 3,4-position and another in a side chain. (2) **X** is a mono-olefinic tricyclic compd. having a phenanthrene skeleton. The 3rd ring is formed around the double bond in the 3,4-position in **I**. This new ring may be formed by the action of both HCO_2H and Se. I. M. LEVINE

Menthone series. VIII. Further characterization of the optically active menthylamines. JOHN READ AND RALPH A. STOREY. *J. Chem. Soc.* **1930**, 2761–9; cf. *C. A.* **24**, 1857.—The following relative mol. configurations assigned to the stereoisomeric menthylamines (**I–IV**), appear to be sustained by the phys. and chem. evidence given below. A study of the rotatory powers of these 4 bases and their derivs. discloses the following relationships: The 4 sets of values are generally related; the 4 bases fall into 2 well-defined families, depending upon their derivation from menthone or isomenthone; *d*-rotatory **IV** belong configurationally to the *l*-series; in general the sign of the optical rotation is changed by reversing asym. center (3) but not by reversing either of the remaining asym. centers, (1) or (4); the lowest rotatory powers, considered numerically,

Me– –H	Me– –H	Me– –H	
–NH_2	H_2N– –H	H_2N– –H	H– –NH_2
H– –iso-Pr	Hi– –iso-Pr	iso-Pr—H	iso-Pr—H
l(or *d*)-Menthylamine (**I**)	*d*(or *l*)-neo-Menthylamine (**II**)	*d*(or *l*)-iso-Menthylamine (**III**)	*d*(or *l*)-neoiso-Menthylamine (**IV**)

are shown by substances of the iso- and neoiso-series, that is, by configurations having the most sym. distribution of like (H) or similar (Me and iso-Pr) groups about a plane passing through the characteristic group (3) at right angles to the plane of the ring, the sequence being usually *l* > *l*-neo > *l*-iso > *d*-neoiso. The m. ps. of derivs. of the *d*-neo- and *l*-bases (menthone series) are usually higher than those of the corresponding derivs. of the *d*-neoiso- and *d*-iso-base (isomenthone series); in each series the neo-derivs. have the higher m. p., the general sequence being *d*-neo > *l* > *d*-neoiso > *d*-iso. The following phys. consts. are reported for *d*-**I**, *d*-**II**, *d*-**III** and *d*-**IV**: b_{12} 81–2°, b_{13} 84°, $b_{13.5}$ 87°, $b_{14.5}$ 89°; d_4^{25} (cor. to vac.) 0.8525, 0.8551, 0.8632, 0.8636; n_D^{25} 1.4600, 1.4614, 1.4659, 1.4670; $[\alpha]_D^{25}$ —44.53°, 15.12°, 28.96°, 2.32°; $[\alpha]_{5461}^{25}$ —53.21°, 17.42°, 34.06°; values are also given for a $CHCl_3$ soln. For the following derivs., the m. p. and $[\alpha]_D$ and $[\alpha]_{5461}^{25}$ ($CHCl_3$, *c* approx. 1) are given. The order is *l*-**I**, *d*-**II**, *d*-**III** and *d*-**IV**. *Acetyl*, 102–3°, —83.8°, —; 117–8°, 53.8°, —; 45–6°, 31.3°, —; —, —3.9°, —. *Acetoacetyl*, 145°, —81.7°, —; 169–70°, 53.0°, —; 77–9°, 30.7°, —; 99–100°, —2.6°, —. *Propionyl*, 88°, —86.6°, —89.6°; 149°, 48.3°, 56.6°; 83°, 27.7°, 32.1°; 103°, 0°, —1.0°. *Butyryl*, 73°, —70.9°, 79.4°; 104°, 46.8°, 53.5°; —, 23.9°, 27.7°; —, —1.0°, —2.0°. *Isobutyryl*, 128°, —66.5°, —75.0°; 160–1°, 47.5°, 54.7°; 116°, 22.8°, 25.9°; 128°, —3.7°, —5.4°. *Isovaleryl*, 110°, — 64.7°, —76.7°; 132°, 42.8°, 51.3°; 82°, 27.0°, 29.1°; 99°, —4.1°, 6.5°. Hexoyl, 60°, —60.0°, —71.2°; 65°, 40.0°, 45.0°; —, 24.9°, 27.5°; 50°, 0°, 1.7°. *Octoyl*, 57°, —53.2°, —63.8°; 78°, 36.7°, 42.4°; —, 23.3°, 26.0°; 55°, —1.2°, 2.9°. *Chloroacetyl*, 76°, —71.9°, —86.6°; 150°, 50.7°, 57.7°; 82°, 30.0°, 35.0°; 80°, 9.8°, —13.0°. *Bromoacetyl*, 103°, —61.6°, —73.1°; 160°, 40.9°, 46.2°; 80°, 30.3°, 37.1°, 100°, —7.5°, —10.3°. Benzoyl, 157°, —62.8°, —; 121.5°, 22.7°, —; 97–8°, 18.3°, —; 151°, —10.4°, —. *Phenylacetyl*, 106°, —60.4°, —72.1°; 120°, 34.5°, 41.0°; 103°, 33.3°, 38.4°; 109°, —3.4°, —5.1°. β-Naphthalenesulfonyl, 135°, —53.3°, —; 208°, 43.7°, —; 80–1°, —2.8°, —; 120°, —10.7°, —. *Anisoyl*, 183°, —57.7°, —69.0°; 130°, 21.1°, 24.0°; 121°, 25.3°, 30.7°; 150°, —9.5°, —11.8°. An inspection of configurations **II** and **I** suggests that the NH_2 group of **II** should react with greater ease than that of **I**, since this group is situated in the *cis*-position to a H atom and an iso-Pr group, resp. Similarly, **IV** should react more readily than **III**. Competitive expts. were there-

fore carried out with binary mixts. of these compds. with various sym. reagents; the compn. of the reaction product was calcd. from its optical rotatory power in $CHCl_3$ and the result checked by a detn. of the rotatory power of the HCl salt prepd. from the recovered mixt. of unchanged bases. Distinct evidence was obtained in this way of the following comparative rates of reaction: *d*-II > *l*-I; *d*-III > *l*-III; *d*-IV > *l*-IV; *d*-II > *d*-III; *d*-IV > *d*-III. Preliminary expts. with *d*- or *l*-camphor-10-sulfonyl chloride showed that the reaction was distinctly more rapid between a *d*-rotatory mol. of 1 reagent and a *l*-rotatory mol. of the other than between a *d*- or *l*-mol. of each kind. The original should be consulted for the details of these expts. C. J. West

Piperitone. XI. Syntheses of optically inactive and active piperitylamines, piperitols and α-phellandrenes. John Read and Ralph A. Storey. *J. Chem. Soc.* **1930**, 2770–83; cf. *C. A.* **24**, 97.—Piperitone and N_2H_4 (1.25 mols.), boiled in dil. MeOH for 6–8 hrs., give a yellow mobile sirup, apparently a hydrated azine, $C_{20}H_{34}N_2O$, α_D 161.6° (EtOH, *c* 2.9145), which loses H_2O at 95° and changes to a dark red, viscid liquid, α_D 35.9°; another prepn. showed α_D 201.1 and 48.3° before and after drying. Upon reducing the quantity of N_2H_4 to 1 mol. proportion, much of the piperitone was recovered unchanged, even after the mixt. had been heated 6 hrs. at 120°. Reduction of this azine with Zn in glacial AcOH gives piperitylamine, b_{16} 97.5–8.5°, α_D 0.5–3.7°, n_D^{16} 1.4802, n_D^{25} 1.4769, d_4^{25} (vac.) 0.8801; *Ac deriv.*, m. 108°; *Bz deriv.*, m. 130°; *anisoyl deriv.*, m. 161°; *HCl salt*, m. 191°; these were optically inactive; the *d*-tartrate had $[\alpha]_D$ 12.6° and after 2 crystns. from H_2O, —43.0°. *l*-Piperitylamine, b_{19} 101–2°, b_{16} 98.2°, d_4^{25} (vac.) 0,8789, n_D^{16} 1.4800, n_D^{25} 1.4770, $[\alpha]_D^{25}$ —80.35°, $[\alpha]_{5461}^{25}$ —95.15°, in $CHCl_3$ (*c* 3.8455), $[\alpha]_D^{25}$ —70.0°, $[\alpha]_{5461}^{25}$ —82.8°; *HCl salt*, m. 213° (decompn.), $[\alpha]_D^{16}$ —83.5° (H_2O, *c* 1.1855); *H d-tartrate*, m. 217°, $[\alpha]_D$ —43.0° (H_2O, *c* 1.0800); *Ac deriv.* m. 102–3, $[\alpha]_D^{25}$ —153°, $[\alpha]_{5461}^{25}$ —183° ($CHCl_3$, *c* 1.2225); *Bz deriv.*, m. 102–3 $[\alpha]_D^{25}$ —173°, $[\alpha]_{5461}^{25}$ —208° ($CHCl_3$, *c* 1.1975); *anisoyl deriv.*, m. 142–3°, $[\alpha]_D^{25}$ —175°, $[\alpha]_{5461}^{25}$ —212° ($CHCl_3$, *c* 1.0725; *phenylacetyl deriv.*, m. 89–90°, $[\alpha]_D^{20}$ —130.5° ($CHCl_3$, *c* 1.1990). When treated with HNO_2 these bases yield piperitols; in practice, however, the most satisfactory results have been attained by steam-distg. mixts. of the iodides and Ag_2O. *dl-Piperityltrimethylammonium iodide*, pale yellow, m. 88° (decompn.), distn. with Ag_2O gives *dl-neopiperitol*, b_{15-5} 94–6°, $n_D^{19.5}$ 1.4740, and *dl-piperitol*, b_{19-5} 100–6°, n_D^{18} 1.4769. Similarly, the active base gives *d-neopiperitol*, b_{15-5} 96.5–8.5°, n_D^{17} 1.4769, n_D^{25} 1.4729, d_4^{25} (vac.) 0.9119, $[\alpha]_D^{16}$ 21.22°, and *d-piperitol*, b_{16} 101–4°, n_D^{16} 1.4770, d_4^{25} (vac.) 0.9200, $[\alpha]_D^{16}$ 40.22°. A complete sepn. of the 2 stereoisomeric piperitols is not claimed at this stage of the investigation. The piperitols, as α,β-unsatd. sec. alcs., undergo dehydration so readily that cryst. esters have not been prepd. In addn to the piperitols, there also results *dl*-α-phellandrene and the *d*-isomer, b_{16} 66–8°, n_D^{16} 1.4827, n_D^{25} 1.4777, d_4^{25} (vac.) 0.8463, $[\alpha]_D^{16}$ 86.4°. On heating the iodide at 150–200°, there results a mixt. of α-phellandrene and α-terpinene. This work thus throws new light on the assocn. of *l*-α-phellandrene with *l*-piperitone in eucalyptus oils. It is also possible to proceed from *l*-piperitone of eucalyptus oils to *d*-piperitol and *d*-piperitone on *Andropogon* species. C. J. West

Crystalline complexes from bornyl and isobornyl acetates. Georges Brus and J. Vebra. *Compt. rend.* **191**, 667–9(1930); cf. *C. A.* **24**, 5294.—Cryst. compds. are formed between isobornyl and bornyl acetates and H_3PO_4, $H_4P_2O_7$, H_3AsO_4, PCl_5, $SbCl_3$, $BiCl_3$, $SnCl_4$ and $ZnCl_2$. The compd. is composed of equimol. ratios except for $H_4P_2O_7$ and isobornyl acetate where the ratio is 2 mols. ester and 1 acid. All these cryst. complexes are unstable and on decompn. regenerate the original ester without isomerization. If bornyl and isobornyl formates react, the complexes are not cryst. Propionates, butyrates and valerates do not react. An oxonium salt structure is suggested. J. G. McNally

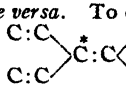
Dependence of optical rotatory power on chemical constitution. IX. (a) Rotatory dispersion of the stereoisomeric oxymethylenecamphors, *p*-phenylenebisaminomethylenecamphors, and 1,4-naphthylenebisaminomethylenecamphors; (b) the structure of oxymethylenecamphor and the kinetics of its mutarotation. Bawa Kartar Singh and Bhutnath Bhaduri. *J. Indian Chem. Soc.* **7**, 771–9(1930); cf. *C. A.* **25**, 98.—A phenomenal depression of the optical rotatory power occurs if the conjugation of the azethenoid group involving the C atoms of the terpene nucleus and the N atoms of the side chain is broken, *i. e.*, $C_6H_4(NC_2O{:}C_8H_{14})_2$ has $[M]_D$ = 6160° and gives $C_6H_4(NHC_2HO{:}C_8H_{14})_2$ with $[M]_D$ = 469°. A. P. Sachs

New complex hydrocarbon of the probable formula $C_{16}H_{16}$. Charles S. Gibson

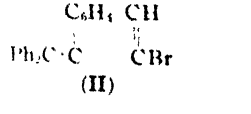
AND JOHN D. A. JOHNSON. *J. Chem. Soc.* 1930, 2785–6.—$(ClCH{:}CH)_2AsCl$ (1 mol.) and 1.1 mol. $AlCl_3$ in C_6H_6, heated 1.5 hrs. and the product decompd. with HCl and C_6H_6, give a fraction b_8 145–230°, from which the *compd.* $C_{16}H_{14}$, pale yellow, m. 179–80°, was obtained from EtOH; it is stable to $KMnO_4$; Br in CCl_4 gives a *di-Br deriv.*, golden yellow, does not m. 310°. C. J. WEST

Some arsonic acids of fluorene and its derivatives. F. E. CISLAK AND CLIFF S. HAMILTON. *J. Am. Chem. Soc.* 53, 746–9(1931).—The diazo compd. from 2-aminofluorene and $NaAsO_2$ with a little $CuSO_4$ give *2-arsonofluorene;* in the same way *2-arsonofluorenone* was prepd. 2-Amino-7-nitrofluorene and Ac_2O in AcOH give 75% of the *Ac deriv.*, m. 250–3° (cor.); reduction with Zn and $CaCl_2$ in EtOH gives 60–5% of the *2-acetamido-7-aminofluorene*, m. 188–92° (cor.); the *arsono deriv.* was obtained in 2–2.5% yields as a dull yellow powder. C. J. WEST

"Supernumerary" isomers. III. Condensation of fluorene with piperonal and *p*-dimethylaminobenzaldehyde. ERNST BERGMANN. *Ber.* 63B, 2598–9(1930); cf. *C. A.* 24, 4025; 25, 919.—In the alk. condensation of fluorene with piperonal and *p* $Me_2NC_6H_4CHO$ de Fazi obtained, along with the expected 3,4-methylenedioxy- and 4-dimethylaminobenzalfluorenes, more deeply colored compds. which, from his analyses, he assumed to be isomeric with the benzalfluorenes. Recently B. (*C. A.* 24, 4515) found that fluorene with BzH, *p*-$MeOC_6H_4CHO$ and α-$C_{10}H_7CHO$ gives, in addn. to the normal fulvenes, their more deeply colored vinylene homologs. This made it seem likely that de F.'s colored compds. might be *3,4-methylenedioxy-* (I) and *4-dimethylaminocinnamylidenefluorene* (II), a supposition confirmed by the synthesis of I and II from $CH_2O_2C_6H_3CH{:}CHCHO$ and $Me_2NHC_6H_4CH{:}CHCHO$ with fluorene. I, yellow, m. 196–7°, did not depress the m. p. of de F.'s compd. (for which he gives 183–4°). II, red, m. 169–70°. C. A. R.

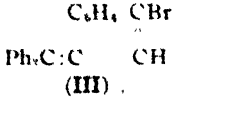


Reduction of triphenylmethane dyes and related substances with the formation of free radicals. JAMES B. CONANT AND NEWELL M. BIGELOW. *J. Am. Chem. Soc.* 53, 676–90(1931).—The action of sol. reducing agents, such as VCl_2, on solns. of Ph_3CH dyes has been investigated, using malachite green as an example and *p*-$Me_2NC_6H_4CPh_2OH$ as a transition compd. between the dyes and Ph_3COH. The first product of the reaction is a free radical, which may be isolated in the assocd. form (deriv. of C_2Ph_6); it shows the typical behavior of these compds. Under the influence of acids, the free radical may further undergo rearrangement or reduction and oxidation to the corresponding methane and carbinol. *p*-$Me_2NC_6H_4CPh_2OH$ in AcOH with VCl_2 or $CrCl_2$ in a N atm. gives *sym-p,p'-tetramethyldiaminohexaphenylethane* (I), flesh-colored, colored bright red on its surface by a crust of oxidized material; even momentary exposure to air decomps. it to a deep red tar, evolving heat and the odor of HCHO; the O absorption of the amorphous powder in PhBr is 75–80% of the theory; the apparent mol. wt. in *p*-ClC_6H_4Me is 458–507 (theory, 572.5); the product could not be recrystd. The relative rates of decompn. in acids of varying strengths are given. The Et_2O soln., exposed to the air, gives *p-dimethylaminotriphenylmethyl peroxide*, light brown, m. 145–50°. With 1% Na-Hg there results the red *Na p-dimethylaminotriphenylmethide;* if the shaking is continued overnight, the soln. becomes colorless and there results *p*-$Me_2NC_6H_4CPh_2H$ and a compd., m. 138°; with CO_2 there results about 29% of *p-dimethylaminotriphenylacetic acid*, amorphous, whose *Me ester* m. 141°. *p*-$Me_2NC_6H_4CPh_2OH$ in Me_2CO and HCl with $CrCl_2$ gives the *compd.* $C_{48}H_{40}N_2$, m. 165° ("Chichibabin product"). Continued action of $CrCl_2$ or $TiCl_3$ in AcOH transforms *p*-$Me_2NC_6H_4CPh_2OH$ to the methane, which also results from I in AcOH after 48 hrs. with or without $TiCl_3$. Malachite green is reduced by VCl_2 in AcOH and AcONa to *sym-p,p',p'',p'''-octamethyltetraaminohexaphenylethane* (II), amorphous powder, light brown in its interior and bright green on its surface; exposure to the air gives a black tar and HCHO; the O absorption varies with the solvent; it is decompd. by AcOH or AcOH-HCl (the latter in 10 min.). Reduction of malachite green in HCl by $CrCl_2$ gives the "Chichibabin product" $C_{46}H_{50}N_2$, m. 231–2°, slowly turns green on standing. The light red of II in Et_2O is discharged by 1% Na-Hg, the resulting product being (*p*-$Me_2NC_6H_4$)CHPh, m. 93–5°. II in AcOH-AcONa with $TiCl_3$ gives 34% of (*p*-$Me_2NC_6H_4)_2CHPh$. Reduction of 1 g. of *p*-$Me_2NC_6H_4CHPhOH$ with $CrCl_2$ in concd. HCl and Me_2CO gives a mixt. of 0.3–0.4 g. of *p,p'-tetramethyldiaminotetraphenylethane*, m. 206–7°, and 0.2 g. of the *isomer*, m. 264–7°; the lower-melting isomer is obtained by the action of Na-K in Et_2O C_6H_6 upon (*p*-$Me_2NC_6H_4CPh{:})_2$. Michler's ketone and $SOCl_2$ in C_6H_6 give the dichloride, bronze-green powder, which is reduced by VCl_2 in Me_2CO-HCl to $(Me_2NC_6H_4)_2C{:}C(C_6H_4NMe_2)_2$, m. 296° (60% of the original ketone). Reduction of $[(Me_2NC_6H_4)_2C(OH)]_2$ with $CrCl_2$ in concd. HCl gives (*p*-$Me_2NC_6H_4CPh{:})_2$ and the octa-Me



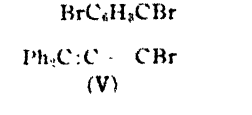
deriv. *p*-Dimethylaminophenylisopropylcarbinol is reduced by $CrCl_2$ in HCl to a mixt of 2 *isomers*, $C_{24}H_{36}N_2$, m. 174° and 239–40°. C. J. WEST

Derivatives of optically active triarylcarbinols and their halochromic salts. EVERETT S. WALLIS. *J. Am. Chem. Soc.* **53**, 812–3(1931); cf. *C. A.* **24**, 2741.—Optically active $PhC_6H_4(C_{10}H_7)CPhSCH_2CO_2H$ (I) gives deep violet halochromic compds. with H_2SO_4, $HClO_4$ and $HgCl_2$, which yield the inactive carbinol, $PhC_6H_4(C_{10}H_7)CPhOH$ on pouring into ice H_2O. $TiCl_4$ in $CHCl_3$ gives a similar compd., which gives with H_2O inactive I. The I regenerated from the $FeCl_3$ salt, however, is optically active. This is evidence against a quinoid formulation for the explanation of color. C. J. W.

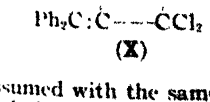


Some alkali-organic experiments (also remarks on the work of Wittig and Leo on the polarizability of the ethylene bond). ERNST BERGMANN *Ber* **63B**, 2593–7 (1930).—W. and L. (*C. A.* **24**, 3776) have convincingly shown, on the basis of much exptl. evidence, that the ethylene double bond can propagate valence-chem. effects in undiminished strength, hence, that it is easily polarizable. B. believes, however, that the case which W. and L. themselves extensively studied has nothing to do with the question. $(Ph_2C.CHCl_2)_2$ with an alkali metal forms an alkali-org. compd. which on hydrolysis (replacement of the metal by H) yields $Ph_2C{:}CHMe$ and with CO_2 (introduction of CO_2 between the metal and the org. residue) gives $Ph_2C{:}CHCH_2CO_2H$. The alkali org. compd. is therefore assigned the structure $Ph_2C{:}CHCH_2M$ (I, M = alkali metal). The explanation of W. and L. is that the valence-requiring action of the Ph groups on the 1- and 6-C atoms is propagated through the double bond to C atoms 3 and 4, so that the C_3–C_4 union is weakened and ruptured by the alkali metal with formation of I. This, however, is not in agreement with the behavior of double bonds toward alkali metals (which add with especial ease to phenylated double bonds) and does not take into consideration the possibility of allyl shifting. B. thinks that the alkali metal first adds at the 1,6-positions and the liberated valences on C atoms 2 and 5 mutually sat. themselves with formation of the cyclobutane deriv. $Ph_2CMCH\,CH_2.CH_2.CHCMPh_2$ which, because of ring tension, is unstable and decomps. into 2 mols. $Ph_2CMCH{:}CH$ and this with H_2O and CO_2 yields $Ph_2C{:}CHMe$ and $Ph_2C{:}CHCH_2CO_2H$ by allyl shifting. This is supported by the behavior of *1,1,8,8-tetraphenyl-1,7-octadiene* (II), readily obtained through the *1,8-octanediol* (III) from di-Me suberate and PhMgBr. It takes up 2 atoms Li to form an intensely brown-red compd. giving on hydrolysis *1,2-dibenzhydrylcyclohexane* (IV); the lack of tension in the cyclohexane system makes a secondary reaction unnecessary. The instability of the cyclobutane system results in an entirely similar secondary decompn. on removal of the metal from compds. of the type $(Ph_2CMCH_2)_2$ (V), with formation of $Ph_2C{:}CH$. That V, which is obtained only by addn. of Na to $Ph_2C{:}CH_2$, really contains the butane skeleton is shown by the fact that it is also obtained from $[Ph_2C(OMe)CH_2]_2$. The removal of the alkali metal is best effected by shaking with Hg. This was explained by Schlenk and Bergmann as due merely to the heat of formation of Na–Hg being greater than that of the alkali org. compd. Ziegler and Colonius (*C. A.* **24**, 3777) recently expressed the opinion that an equil. $PhCHNaCHNaPh + Hg \rightleftharpoons PhCH\underset{Hg}{\overset{}{\quad}}CHPh + Na$ is established and that the 3-membered Hg ring is unstable, decompg. into the ethylene and Hg and thus continuously shifting the equil. at the expense of the alkali compd. Ph_2CHNa also establishes an equil. with Hg but the Hg compd., having no ring tension, does not decomp., the equil. is not disturbed and the Ph_2CHNa remains for the most part unchanged. B. has found, however, that, contrary to the statement of Z. and C., Ph CHNa gives $(Ph_2CH)_2$ quite readily with Hg (*C. A.* **2**, 4515). *Di-Me suberate*, from the acid and CH_2N_2, b_{21} 138–40°. **III**, m. 110°, gives with AcOH contg. some H_2SO_4 on the H_2O bath **II**, m. 92–3°, mol. wt. in camphor 380. **IV**, m. 212–3°, mol. wt. in camphor 397–401. *1,1,4,4-Tetraphenylbutane-1,4-diol di-Me ether* (**VI**), from the diol with H_2SO_4 in MeOH-dioxane, m. 230°, mol. wt. in camphor 375. With K and MeI in boiling xylene the diol gives the *mono-Me ether*, m. 175–6°. *1,1,4,4-Tetraphenyl-2-butine-1,4-diol di-Me ether* (**VII**), from the diol and H_2SO_4 in MeOH, m. 115–6°; attempts to convert it into **VI** by catalytic hydrogenation with Pd–$BaSO_4$ in boiling PrOH resulted in splitting off of one MeO group with formation of *1,1,4,4-tetraphenyl-1-butanol Me ether*, m. 140–1°. **VII** reacts normally with Na, each OMe group being replaced by Na; hydrolysis of the brown product gives 2 hydrocarbons, m. 97° and 167°, to be described elsewhere, and treatment with PhNCS gives *1,1,4,4-tetraphenyl-2-butine-1,4-dithiocarboxanilide*, yellow, m. 204°, mol. wt. in camphor 577.

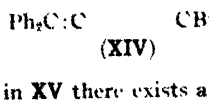
The double bond. I. Action of halogens on fulvenes. ERNST BERGMANN AND



ALFRED FREIHERR VON CHRISTIANI. *Ber.* **63B**, 2559-71(1930).—It was shown recently (Schlenk and B., *C. A.* **24**, 3778) that the more easily an ethylene adds halogens, the more difficultly does it add alkali metals, and *vice versa*. To obtain further exptl. data the study has been extended to the fulvenes,  . Staudinger had concluded, on the basis of Thiele's partial valence theory, that the characteristic C atom (marked with an *) in these compds. would possess very little residual affinity while expts. in the field of alkali-org. compds. had shown that it has to a very high degree the ability to add alkali metals. A study of the action of halogens (Cl and Br) has now shown that this C atom is practically entirely unable to add halogens. Addn. to an ethylene is in every case primarily asym.; the halogen first adds molecularly to one of the C atoms and the resulting intermediate compd. changes into the final reaction product only in a 2nd phase by intramol. neutralization of valences. This stabilization may take place in various ways—by a change of the intermediate product into the normal dibromide of the ethylene (the usual reaction) or by the formation, within the same mol., of substitution products by the molecularly bound halogen. It is probable that in a secondary valence compd., such as the intermediate product may be assumed to be, the mol. union of the halogen atoms is loosened, *i. e.*, the halogen is activated and thereby enabled to effect substitutions. The yellow diphenylbenzofulvene (**I**) reacts smoothly with 2 atoms Br in $CHCl_3$, forming HCl and a yellow mono-Br substitution product (**II** or **III**). **III** is given the preference as the entrance of halogen in the α-position of a fulvene generally results in a deepening of the color. Certain it is, as shown especially by the yellow color of the product, that the characteristic fulvene double bond has not been attacked. With more than 2 atoms Br it is not possible to obtain the di-Br deriv. (**IV**) which is substituted in the C_6H_6 nucleus with such extraordinary ease that when 4 atoms Br is used with **I**, a part of the **I** reacts with 6 atoms Br to form the red-yellow tri-Br deriv. (**V**) which on oxidation yields *2,3,6-tribromoindone* (**VI**), whose structure seems to be established by the fact that 2,3-dibromoindone, obtained from PhCBr $CBrCO_2H$, forms an oxime which with Br yields a tri-Br oxime identical with the oxime of **VI**. The 3rd Br atom is probably in the *m*-position to the fulvene C atom, for in diphenyldibenzofulvene (**VII**) Br enters the *m*-position (see below) and bromination of Ph_2CO gives $(m\text{-}BrC_6H_4)_2CO$. Toward Cl, **I** reacts essentially the same as toward Br. With 1 mol. Cl it forms a bright yellow *mono-Cl deriv.* (**VIII**); 4 atoms Cl give an orange-red *di Cl deriv.* (**IX**) (probably because Cl has a lower substituting power than Br), oxidized to 2,3 dichloroindone and Ph_2CO; still more Cl gives a dichloride (**X**) of **IX** which on fusion decomps. into **IX** and Cl. In triphenylbenzofulvene, Cl substitutes the α H atom, giving the red-violet 1-benzohydrylidene 2-chloro-3-phenylindene (**XI**), while Br gives a di-Br deriv. (**XII**), in which 1 of the Br atoms is substituted on the C_6H_6 nucleus and which is oxidized to a *2,6-dibromo-3-phenylindone* (**XIII**). Diphenylfulvene with excess of Br gives, in moderate yield, a tetra-Br deriv. which, because of its bright blue color, is assigned the structure **XIV**. **VII** yields a di-Br deriv. (**XIVa**) oxidized to Ph_2CO and 2,7 dibromofluorenone. Staudinger has already shown that the "open" fulvene $(PhCH{:}CH)_2C{:}CPh_2$ yields a tetrabromide $(PhCHBrCHBr)_2C{:}CPh_2$, and it has now been found that $(PhCH{:}CHCH{:}CH)_2C{:}CPh_2$, with its 5 double bonds, consumes exactly 4 mols. Br when titrated with Br. In view of the above, it might perhaps seem surprising that $(C_6H_4)_2C{\cdot}C(C_6H_5)_2$ (**XV**), as found by Graebe and Mayer, can add Br and Cl. B. and von C. believe that this is due to the fact that it



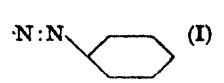
(**II**)

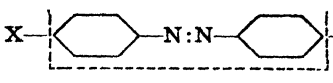


(**III**)

(**V**)

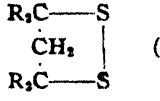
(**X**)



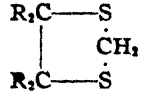


(**XIV**)

can only be assumed with the same strictness that in **XV** there exists a crossed conjugation. Hexanthylene (**XVI**) and benzalxanthene (**XVII**), however, in which the double bonds of the C_6H_6 nuclei are fixed in the positions requisite for a crossed conjugation, also add halogen at the characteristic C atom. But the chem. properties of the halogen addn. products of **XV, XVI and XVII** show that they are compds. of a peculiar kind whose



halogen cannot be compared with, say, the Br in $(CH_2Br)_2$. Thus the Br compd. of XV regenerates XV with alc. KOH instead of giving a glycol. No normal dibromide could be obtained from XVI and XVII; XVI gives a hexabromide (XVIII) and XVII a *tetrabromide* (XIX). Both of these compds. contain labile Br. XVIII converts $PhNMe_2$ into Me violet on warming, and XIX in boiling $CHCl_3$ splits off Br and HBr and gives *ω-bromobenzalxanthene* (XX). XVIII and XIX must therefore be perbromides, formed for the same reason that triarylmethyl halides have a tendency to form perhalides; in the triarylmethyl halides, the entire affinity of the halogen is not used up and the residual affinity can come into play in the formation of a mol. addn. compd. So, also, the union of halogen to fulvene C atoms does not use up the whole valence energy of the halogen. These facts point to a parallelism between the triarylmethyls and fulvenes; it had already been established that all ethylenes are in equil. with a diradical form and that, with the fulvenes especially, the latter form is favored at the expense of the true ethylene form. A large no. of colored fulvenes, when cooled in liquid air, show a distinct lightening of color, and XV, which is almost colorless at room temp., gives a reversible intensely blue color when heated in high-boiling solvents. *1-Benzohydrylidene-2(3)-bromoindene* (II or III), m. 151°, mol. wt. in camphor 328, is almost colorless in liquid air, with CrO_3-AcOH it gives a bright red *compd.* $C_{28}H_{14}O_3$, m. 236°, giving a bright emerald-green color with concd. H_2SO_4. *1-Benzohydrylidene-2,3,6-tribromoindene* (V), m. 168°, mol. wt. in camphor 516–23, almost colorless in liquid air. VI, golden-yellow, m. 145°, mol. wt. in camphor 358–65, forms with $PhNHNH_2$ in boiling PrOH *2,3-bis(phenylhydrazino)-6-bromoindone phenylhydrazone*, brown-red, decomps. 250°. *Oxime* of VI, m. 231° (decompn.). *2,3-Dibromoindone oxime*, m. 222° (decompn.). *1-Benzohydrylidene-2(3)-chloroindene* (VIII), m. 142–4°, mol. wt. in camphor 277–85. IX, m. 130–1°, mol. wt. in camphor 325–54. *1-Benzohydrylidene-2,2,3,3-tetrachlorohydrindene* (X), yellowish, m. 170° (decompn.), mol. wt. in camphor 382–8. *1-Benzohydrylidene-2,6-dibromo-3-phenylindene* (XII), red, m. 145–6°. XIII, brick-red, m. 163°, mol. wt. in camphor 396–7°. *1-Benzohydrylidene-2,3,4,5-tetrabromocyclopentadiene* (XIV), m. 190–1°. *2,7-Dibromo-9-benzo-hydrylidenefluorene* (XIVa), m. 220–2°. XIX, bright red, m. 140° (decompn.). XX, m. 110° (decompn.). II. (Also significance of dipole measurements for the stereochemistry of carbon. IV.) Spatial configuration of aromatic azo compounds. ERNST BERGMANN, LEO ENGEL AND STEFAN SÁNDOR. *Ibid* 2572–5; cf. *C. A.* 25, 242.—The azo group resembles the ethylene system as regards possibilities of isomerism; the *syn-anti* isomerism of the diazotates corresponds to the *cis-trans* isomerism of substituted ethylenes. In principle such an isomerism is also possible in the azo hydrocarbons, although it had hitherto not been observed, probably because this question had never been seriously discussed and also because there was no method of settling it with certainty. This, however, can be done by the dipole method. Two laws have been firmly established, both theoretically and experimentally: (1) Centro-sym. mols. have the dipole moment 0. (2) In any given mol. there is always a greater part which is centro-sym. and therefore has the moment 0; from it there go out valence lines to other substituents. The latter have characteristic moments, directed magnitudes whose direction (at least in the simple cases discussed in this paper) coincides with the valence line. The vectorial summation of these individual moments gives the dipole moment of the mol. Azobenzene, if it has the centro-sym. form I, must have the moment 0. *p*-Substituted azobenzenes (II) must, if the formulation corresponding to I holds, have a moment which can be calcd. on the basis of (2). From the large centrosym. part of the mol. (designated by the dotted line) there go out the vectors of the substituent moment M_X and that (M_H) of the H atom in the other *p*-position. The moment of the mol. is therefore $M_X - M_H$. Since the moment of aromatically bound H is, by definition, 0, the moment of the mol. must be equal to that of the halogen X if the *trans*-formulation is correct, otherwise not. *p,p'*-Disubstituted azobenzenes with identical substituents must have a moment 0 if they have the centro-sym. structure, otherwise they must have a strong finite moment. As a matter of fact, PhN:NPh has the moment 0, *p*-chloro- and *p*-bromoazobenzene have exactly the dipole moment of Cl and Br, which is that of PhCl or PhBr, resp., and (*p* $BrC_6H_4N:)_2$ has the moment 0. The azo hydrocarbons, therefore, have the *trans*- or *anti*-structure. This is supported by the fact that PhN:NPh forms mixed crystals with stilbene (*trans*-) but not with isostilbene. The dipole moment was detd. in the usual way from the orientation polarization (P_{A+O}), the latter being the difference between the total polarization P and the electron polarization P_E. P is obtained from the dielec. consts., P_E is equal to the mol. refraction. For PhN:NPh, however, the mol. refraction, both as measured and as calcd. from the equivs. for a double bond and 2 tertiary N atoms, was greater than the measured total polarization. Since,



theoretically, the electron polarization cannot be greater than the total polarization, the electron polarization for PhN:NPh was taken as equal to its total polarization and this value was used in calcg. P_E for the other compds. by subtracting 1 (or 2) H equivs. and adding a Br or Cl equiv. The moments for *p*-ClC_6H_4N:NPh and *p*-BrC_6H_4N:NPh

(I)

(II)

were found to be 1.55 and 1.42 × 10^{-18} electrostatic units, resp. **III. Aromatic thio ketones, especially their reaction with diazomethane.** ERNST BERGMANN, MICHAEL MAGAT AND DAVID WAGENBERG. *Ibid* 2576–84.—Staudinger and Kon had found that, although Ph_2CS (I) is blue and the C:S group is therefore a strong chromophore, the introduction of auxochromic groups lightens instead of deepens the color; (*p*-MeO-$C_6H_4)_2CS$ (II) forms solns. with a distinct reddish tinge and (*p*-$Me_2NC_6H_4)_2CS$ pure red solns. Also, the reactivity towards Ph_2CN_2 *decreases* in the order I ⟶ II ⟶ III. Wieland, Popper and Seefried observed a similar lightening of the color on the introduction of *p*-Me_2N groups into the triarylmethyls. This anomaly of the triarylmethyls and aromatic thio ketones is probably due to similar anomalies in mol. structure, *i. e.*, the thio ketones contain tervalent C and the color of aromatic thio ketones is due to the fact that they exist entirely or in part in the form of diradicals: $R_2C{:}S \rightleftharpoons R_2C.S$ (cf. B. and Engel, *C. A.* **24**, 4274). Further evidence in favor of this view is presented. Like Ph_3C, 2 mols. I take up 1 mol. O_2 to form an unstable peroxide, III is quite stable to atm. O but while II is also quite stable its solns. gradually become colorless in the air. The color of thio ketones lightens on cooling; II in PhMe in Me_2CO-CO_2 cooling mixt. has a color very similar to the red of III and again becomes blue on warming. Unlike C:O compds., in the thio ketones it is the C, not the S, which is first attacked on reduction. With satd. alc. NH_4SH, I, II and III yield disulfides, $(R_2CS)_2$. With CH_2N_2, I, II and xanthione (IV) form well-crystd. compds. of the compn. $2R_2CS + CH_2$ which, *a priori*, might have the structure V or VI. The compd. obtained from II gave, with Zn and AcOH-HCl, [(*p*-$MeOC_6H_4)_2C{:}]_2$ (VII), showing that the structure VI is the correct one and the compd. is ***4,4,5,5-tetra-p-anisyl-R-trimethylene 1,3-disulfide*** **(VIII)**. The authors do not agree with Meerwein that the difference in the behavior of aromatic ketones and thio ketones toward CH_2N_2 is due to the fact that the dipole moment of the thio ketones is increased by the great polarizability of S, for the red 2,3-diphenylindone also has a larger moment (3.3 × 10^{-18} electrostatic units) than is normally the case for ketones and yet does not react with CH_2N_2. They believe also that the role of H_2O in the action of CH_2N_2 on Me_2CO is not to be explained by an addn of H_2O on the C:O group resulting in an increase of the moment of the C:O group or a liberation of a spatially enclosed or electrostatically screened dipole, but rather that under the catalytic influence of ions (especially H ions) the CH_2N_2 decomps. into CH_2 and N_2 and in the presence of H_2O the CH_2 adds H_2O to form MeOH. *Tetra-p-methoxydibenzohydryl disulfide*, m. 128° without color, becomes blue only at a higher temp VIII, m. 161–2° (blue melt). *Tetra-p-anisylethylene* **(VII)**, m. 177° (yellow), colored blue by H_2SO_4 and by PbO_2-AcOH, mol. wt. in camphor 426, also obtained

(V)

(VI)

from II with Cu bronze in CO_2 at 210°. ***4,4,5,5-Tetraphenyl-R-trimethylene 1,3-disulfide***, from I, m. 166–7° (deep blue), mol. wt. in C_6H_6 439. ***4,5-Bisxanthylene-R-trimethylene 1,3-disulfide***, from IV, m. 224° (with the color of IV), mol. wt. in C_6H_6 426. III gave a compd. m. 144°, mol. wt. in C_6H_6 307, whose compn. (C 70.1, H 7.8, S 10.1%) did not correspond with any definite formula. C. A. R.

Action of diphenylmethyl sodium on aromatic ketones and thio ketones. ERNST BERGMANN AND DAVID WAGENBERG. *Ber.* **63B**, 2585–92(1930).—Like aromatic ketones, thio ketones also give, with Ph_2CHNa, tertiary thio alcs. which, to be sure, are relatively labile and on heating alone or, better, with AcCl, lose H_2S and yield the corresponding ethylenes. With (*p*-$Me_2NC_6H_4)_2CS$ the thio alc. could not be isolated in pure form as it decompd. into the ethylene on even a slight elevation of the temp. Attempts to methylate the thio alcs. with CH_2N_2 failed, nor could the corresponding

O compds. be methylated with K and MeI. Well-characterized derivs. can be prepd., however, from their Na compds. as obtained directly from the ketones with Ph_2CHNa. Thus, $Ph_2CHC(ONa)Ph_2$, obtained from Ph_2CO, although it is decompd. by PhNCS into $(Ph_2C:)_2$ and NaOH, gives the *phenylurethan*, $Ph_2CHC(O_2CNHPh)Ph_2$ (I) with PhNCO. BzCl in its reaction occupies an intermediate position; with an excess of BzCl only $(Ph_2C:)_2$ is formed, probably as the result of a secondary reaction for less than 1 mol. BzCl gives the expected *benzoate* (II) which m. 155° but resolidifies about 180° and m. again around 210° ($(Ph_2C:)_2$ m. 222°). $(PhCH:CH)_2CO$ (III) and $(PhCH:CHCH:CH)_2CO$ (IV) do not form tertiary alcs. The reaction with IV probably consists in 1,4-addn. with formation of *1,9-diphenyl-3-benzohydryl-1,6,8-nonatrien-5-one* (V): IV + Ph_2CHNa ⟶ $PhCH{\cdot}CHCH{:}CHC(ONa){:}CHCH(CHPh_2)CH{\cdot}CHPh$ ⟶ V; the product still contains 3 double bonds. III, on the other hand, gives a fully satd., HO-free product which is supposed to be *3,4,4,5-tetraphenylcyclohexanone* (VI). *1,1-Di-p-tolyl-2,2-diphenylethanol*, from $(p\text{-}MeC_6H_4)_2CO$ and Ph_2CHNa, m. 155–6°, gives with boiling AcCl *1,1-di-p-tolyl-2,2-diphenylethylene*, m. 161°. *1,1-Di-p-anisyl-2,2-diphenylethanol*, m. 183°; *ethylene*, m. 155°, mol. wt. in camphor 351. *1,1,2,2-Tetraphenylethaneëthiol*, from Ph_2CS and Ph_2CHNa, m. 167–8°. *1,1-Di-p-anisyl analog*, m. 155°. *2,2-Diphenyl-1-xanthyleneëthanethiol*, from xanthione, m. 159° to a red-green dichroitic liquid (xanthione). I, m. 163.5° (decompn.). VI, m. 170–2°. V, m. 145–6°.

C. A. R.

The ketene-imines and the tautomerism of nitriles. Georges Mignonac and Charles Hoffmann *Compt. rend.* **191**, 718–20(1930).—MeCN treated with EtMgBr forms a cryst. compd $CH_2(CN)MgBr$ (I). This latter compd. forms $AcNH_2$ in water at 0° under such conditions that MeCN does not hydrolyze. M. and H. believe that I reacts with H_2O to form a ketene imide, which rearranges to acetamide. Evidence that this may be so was obtained from the reaction between cyanodesoxybenzoin and $PhCH_2CH_2NH_2$, where a yellow-green compd is formed which is thought to be a salt of the pseudo acid Ph(PhCO)C C·NH (II) and $PhCH_2CH_2NH_2$. On raising the temp. of the soln., the green color vanishes. The change is considered to be caused by the rearrangement of II to the colorless nitrile Ph(PhCO)CHCN. J. G. McNally

Optically active diphenylhydroxyethylamines and isohydrobenzoins. IV. Di-*p*-methoxyphenylhydroxyethylamine and di-3,4-methylenedioxyphenylhydroxyethylamine. John Read and Isbbel Grace Macnaughton Campbell. *J. Chem. Soc* **1930**, 2674–81; cf. *C. A.* **25**, 289. $H_2NCH_2CO_2H$, *p*-$MeOC_6H_4CHO$ and NaOH in MeOH, kept 10 hrs. at 50°, give the *anisylidene deriv.*, m. 116°, of *dl-di-p-methoxyphenylhydroxyethylamine* (I), m. 135.5°; *mono-Ac deriv.*, m. 145.7°; *di-Ac deriv.*, m. 169–71°; *benzylidene deriv.*, m. 125–6°; *salicylidene deriv.*, pale yellow, m. 134.5°; *chloroplatinate*, bright yellow, m. 171° (decompn.) *l*-I (II), m. 111.2°, $[\alpha]$ 150° (abs. EtOH, *c* 0.9520), was obtained through the *H d tartrate*, m. 110.1°, crystals with 1 mol. H_2O, $[\alpha]_D^{15}$ —66.7 (H_2O, *c* 1.0645); *HCl salt*, m. 188–90°, $[\alpha]_D^{15}$ —99° (H_2O, *c* 0.5805); *mono-Ac deriv.*, m. 128–9°, $[\alpha]_D^{15}$ —16.9° (abs. EtOH, *c* 0.5025); *di-Ac deriv.*, m. 160–1°, $[\alpha]_D^{15}$ 44.6° (abs. EtOH, *c* 1.1650); *benzylidene deriv.*, m. 136° (abs. EtOH, *c* 0.5050); the *d*- and *l*-camphor-10-sulfonates were vitreous substances but the *l-salt* crystd. after 2 months, m. 163°, $[\alpha]_D^{15}$ —76.9° (H_2O, *c* 1). The action of $NaNO_2$ on II in *N* H_2SO_4 gives *cis-α,β-di-p-methoxyphenylethylene oxide* (III), m. 142–3°, optically inactive and stable on boiling 3 hrs. with 7.5% H_2SO_4 or 8% NaOH and unchanged by cold concd. H_2SO_4 after 6 hrs.; mol. wt. detn. in C_6H_6 did not indicate polymerization. The mother liquor contained hydroanisoin. I, MeI and MeONa give the *trimethylammonium iodide*, m. 155° (decompn.); with Ag_2O in H_2O this yields III; II gives an *iodide*, m. 145° (decompn.), $[\alpha]_D^{15}$ —34.6° (MeOH, *c* 1.5475), which likewise gives III with Ag_2O. With piperonal and $H_2NCH_2CO_2H$ there results *dl-di-3,4-methylenedioxyphenylhydroxyethylamine* (IV), m. 159°; *piperonylidene deriv.*, pale yellow, m. 177°; *chloroplatinate*, deep yellow, m. 184° (decompn.). *l*-IV, m. 164°, $[\alpha]_D^{15}$ —196° (abs. EtOH, *c* 0.7320) was obtained through the *H d-tartrate*, m. 208° (decompn.), $[\alpha]_D^{15}$ —104.2 (H_2O, *c* 1.0930); *HCl salt*, vitreous mass, $[\alpha]_D^{15}$ —131°; *di-Ac deriv.*, m. 222–4°, $[\alpha]_D^{15}$ —38.5° (abs. EtOH, *c* 0.2850); *d*-IV, m. 164°, $[\alpha]_D^{15}$ 196° (abs. EtOH, *c* 0.4575); *H d-tartrate*, m. 145°, $[\alpha]_D^{15}$ 117.1° (H_2O, *c* 0.7680), crystals with 1 mol. H_2O. V. **β-Hydroxy-β-phenylethylamine and some derivatives.** *Ibid* 2682–5.—Details are given of the prepn. of $HOCHPhCH_2NH_2$ (I) from styrene, Br-H_2O and concd. NH_4OH; the HCl salt m. 213° (decompn.); the Bz deriv. m. 148°; the *benzylidene deriv.* m. 111–2°; the *d-methylenecamphor deriv.* m. 106–8°, $[\alpha]_D^{15}$ 230° (abs. EtOH, *c* 1.0550); the *d-camphor-10-sulfonate* m. 125–6°, $[\alpha]_D^{16}$

52.8° (H_2O, *c* 1.0090). Resolution of **I** was effected by *d*-tartaric acid. ***d*-I *d-tartrate***, m. 210°, $[\alpha]_D^{15}$ 46.1° (H_2O, *c* 0.9650); the *d*-base was obtained as a mixt. with the carbamate, m. 67°, $[\alpha]_D^{15}$ 28.3° (abs. EtOH, *c* 1.7655); with MeI and MeONa there results 80% of the ***trimethylammonium iodide***, m. 223-4°, $[\alpha]_D^{15}$ 4.5 (MeOH, *c* 1.6725); on steam distn. with Ag_2O there results some BzMe, possibly a little $PhCH(OH)CH_2OH$ and ***d*-phenylethylene *oxide***, $b_{0.5-1.0}$ 200°, $n_D^{17.5}$ 1.5572, $[\alpha]_D^{15}$ 36.4° (C_6H_6, *c* 3.1815), 28.9° (abs. EtOH, *c* 2.7790); this may be a polymeric form. The action of HNO_2 was not studied. C. J. West

1-Methylnaphthalene derivatives. Karol Dziewoński and Tadeusz Waszkowski. *Bull. intern acad Polonaise* **1929A**, 604-10(in German).—1,7-$C_{10}H_6MeSO_3H$ (**I**) may be prepd. by dropping cond. H_2SO_4 into $C_{10}H_7Me$ (b. 240-3°), previously heated to 150°; the fused mixt. is kept at 165-70° for 5-6 hrs., cooled, dissolved in water, washed with C_6H_6 and the **I** pptd. with $BaCO_3$ as the Ba salt (finally recrystd from hot water), $BaC_{22}H_{18}O_6S_2$ (**II**), difficultly sol. in water. The Na salt $NaC_{11}H_9O_3S$ (**III**), prepd. by interaction of **II** with Na_2CO_3, leaflets from boiling dild. EtOH, very sol in water. The aniline salt, $C_{17}H_{17}O_3NS$, from boiling water, m. 248-50°. Chloride (**IV**) from **III** with PCl_5, m. 120-2°. Amide, prepd. by refluxing **IV** with 10 parts aq. NH_3, m. 188-9°. 1-Methyl-7-hydroxynaphthalene (**V**) is prepd. by fusing **III** with KOH plus a little water at 180°, heating the reaction mass at 260° for 10 min., dissolving the cake in water and acidifying with HCl. The ppt. is sol. in EtOH, Et_2O, C_6H_6, difficultly sol. in cold water. It may be recrystd. from ligroin or much boiling water. 1-Methyl-7-benzoyloxynaphthalene m. 107-8°. 8-Benzeneazo-1-methyl-7-hydroxynaphthalene is prepd. by coupling PhN_2Cl with **V** in alk. carbonate soln., vivid red, m. 137°, moderately sol. in most of the org. solvents, difficultly sol. in alkalies. 8-(4'-Nitrobenzeneazo)-1-methyl-7-hydroxynaphthalene is obtained by coupling p-$O_2NC_6H_4N_2Cl$ with **V** in alk. carbonate soln; carmine-red, m. 258-60°, slightly sol. in EtOH, AcOH, readily sol. in toluene, xylene, insol. in aq. alkalies. 1-Methyl-7-aminonaphthalene is prepd. by heating **V** with $(NH_4)_2SO_3$ and concd. NH_4OH with little water in a sealed tube at 150-70° and fractionating the resulting dark oil, bright yellow oil, b_5 170-80°, congeals to fine needles which, recrystd. from ligroin, m. 46-7°. The crystals become rose-colored in the air and are sol. in Et_2O, EtOH, C_6H_6 and difficultly sol. in boiling water. 1-Methyl-7-acetylaminonaphthalene m. 146°. J. Wiertelak

Labile compound of benzeneazo-β-naphthol and β-naphthol. Herbert H. Hodgson and Wolf Rosenberg. *J. Chem. Soc.* **1930**, 2787-9.—PhN_2X and β-$C_{10}H_7OH$ in 1 equiv. aq. NaOH and excess NaOH give a *compd* of ***benzeneazo-β-naphthol*** and ***β-naphthol***, crystg. with 1 mol. C_6H_6, m. 62-4°; this effloresces, leaving the brick-red *compd.*, m. 79-80°, crystn. from AcOH, C_5H_5N or EtOH gives benzeneazo-β-naphthol (**I**), m. 133-4°, which is the only product obtained when the coupling is carried out in aq. NaOH, $NaHCO_3$, AcONa or Na_3BO_3. PhN_2HSO_4 and β-$C_{10}H_7ONa$ in equimol. proportions give the double compd. exclusively. Neither β-$C_{10}H_7OH$ nor **I** forms a compd. with C_6H_6. C. J. West

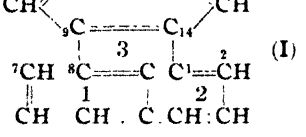
Potentials and the decomposition reactions of *o*-quinones in acid solution. Louis F. Fieser and Mary A. Peters. *J. Am. Chem. Soc.* **53**, 793-805(1931).—By means of potentiometric analysis it is shown that β-naphthoquinone (**I**) decomps. in dil. acid soln. to give equal parts of β-naphthohydroquinone (**II**) and 2-hydroxy-1,4-naphthoquinone (**III**). Since the reaction is monomol., it is concluded that the first step in the disproportionation is the addn. of the elements of H_2O to **I**. 3,4-Phenanthrenequinone (**IV**) behaves in a similar manner and it is presumed that the reaction is characteristic of all of the unsubstituted *o*-quinones. Discontinuous titration of **I** at 25° with $K_3Mo(CN)_8$ gives the normal oxidation-reduction potential of the system as 0.5760 v. The speed of the reaction **I** + H_2O controls the velocity of decompn. of the reaction product into **II** and **III**. The titration curve for dinaphthyldihydroquinone is given; this shows 2 distinct inflections; the first half of the curve refers to the potentials of the system formed by the reductant and dinaphthyldiquinhydrone; the upper half refers to the equil. between the monoquinone and the diquinone, dinaphthyldiquinone; the normal potentials detd. were 0.5723 and 0.6420 v. The normal potential of **IV** was detd. to be 0.6215; the decompn. products of **IV** contains more hydroquinone than hydroxyquinone, because of the cleavage of the hydroxyquinone in acid soln. 1,2-Dihydroxyphenanthrene has a normal potential of 0.6601 v. Catechol in 0.5 *N* H_2SO_4 has a normal potential of 0.7943 v.; in *N* H_2SO_4, 0.7891 v. C. J. West

Derivatives of aminomethylhydroxyanthraquinones and of dihydroxydianthraquinonylethylene. III. Henri de Diesbach, Paul Gubser and Henri Spoerenberg. *Helv. Chim. Acta* **13**, 1265-74(1930); cf. *C. A.* **24**, 2744.—To prep. ***1-chloro-2-***

aminoanthraquinone (I) 2-$C_6H_4(CO)_2C_6H_3NHAc$ was chlorinated in HOAc, the product recrystd. and hydrolyzed with concd. H_2SO_4 on the water bath. I was heated at 180–200° with 10 parts of a mixt. of 70 g. $NaNO_2$ and 1 l. concd. H_2SO_4, cooled, and the resulting *1-chloro-2-hydroxyanthraquinone* (II) recrystd. from EtOH, m. 224°. II (2 g.) in 20 cc. concd. H_2SO_4, shaken with 3 g. $CCl_3CONHCH_2OH$ for 3 hrs., cooled on ice, the ppt. washed, dried, extd. in a Soxhlet app. with EtOH yielded *3-trichloroacetylaminomethyl-1-chloro-2-hydroxyanthraquinone* (III). III, recrystd. from a 50% mixt. of HOAc and cyclohexanol, m. 204°. It was slightly sol. in Et_2O, EtOH and C_6H_6, but dissolved readily in HOAc and org. solvents of high b. p. In concd. H_2SO_4 it gave an orange and in caustic alkali a red soln. One part III was boiled 15 min. with 10 parts 10% NaOH, the product acidified with HOAc and the ppt. extd. in a Soxhlet app. with HOAc. The residue, recrystd. from $PhNO_2$, was assumed to be *3,3'-(2,2'-dihydroxy-1,1'-dichlorodianthraquinonyl)-α-hydroxy-β-aminoethane*, m. about 250°, in which the labile Cl atom could easily be replaced by NH_3 liberated in the reaction, thus accounting for low Cl and high N values found on analysis. In concd. H_2SO_4 it gave a brown and in caustic alkalies a brown-red soln. It did not dye cotton. These properties indicate the 3- and not the 4-position for the methylol combination. Alizarin (IV) was condensed with dimethylolurea (V) by adding 2 g. V to 2 g. IV in 20 cc. concd. H_2SO_4. The product, washed with EtOH and recrystd. from $PhNO_2$, gave *α-[(1,2-dihydroxyanthraquinonyl-3)-methyl]-β-hydroxymethylurea* (VI), m. 204°. It was yellow-red in concd. H_2SO_4 and blue in caustic alkali. *3-Phthaloylaminomethyl-1,2-dihydroxyanthraquinone* (VII), m. 310°, was similarly formed from methylolphthalimide. One part VI was hydrolyzed with 10 parts concd. H_2SO_4 at 60°, the temp. raised to 160°, and the acid dild. with water to 60%. The mixt. was cooled, neutralized to a blue color and treated with HOAc until colorless. A ppt. of *3-aminomethyl-1,2-dihydroxyanthraquinone* (VIII) formed. It could not be crystd. In HCl VIII gave a yellow, in concd. H_2SO_4 a brown soln. Five g. VI, heated 4 hrs. at 170° in a sealed tube with 20 cc. HOAc satd. with HCl, gave a ppt. of VIII contg. 1 mol. HOAc. VIII, heated with 23% NaOH, cooled, acidified and heated 4 hrs. with HOAc at 170°, gave *3,3'-(1,1',2,2'-tetrahydroxydianthraquinonyl)-α-hydroxy-β-aminoethane*. *1,1'-(2,2'-Dihydroxydianthraquinonyl) dimethylurea* (IX), m. 250°, was obtained from 6 g. 2-hydroxyanthraquinone in 60 cc. concd. H_2SO_4 and 2.4 g. V. IX heated in a sealed tube at 150° with concd. HCl gave dianthraquinonylethylenediamine mixed with the corresponding glycolic deriv. *1,1'-(2,2'-dihydroxy-3,3'-dicarboxydianthraquinonyl)dimethylurea* (XI) was obtained similarly from 6 g. 2,3-$C_6H_4(CO)_2C_6H_2(OH)SO_3H$ and 2.6 g. V in 120 cc. concd. H_2SO_4. The pyridine salt of XI decompd. 318°. It was yellow in concd. H_2SO_4 and red in alk. soln. XI, boiled 4 hrs. with concd. HCl, gave *2-hydroxy-3-carboxyisopyrroleanthrone* (XII) and the corresponding amine (XIII). XII and XIII were not transformed into ethylene derivs. by HNO_2 or by O_2 in alk. soln., but when heated with HCl at 150° or HOAc at 170° in a sealed tube the 2 mols. united and with auto-reduction gave the ethylenediamine deriv. mixed with the corresponding glycolic deriv. RACHEL BROWN

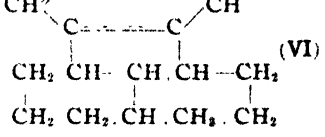
5,6,5',6'-Dibenzo-*N*, *N'*-dihydro-1,2,1',2'-anthraquinonazine. ERW. SCHWENK AND HANS WALDMANN. *J. prakt. Chem.* **128**, 320–6(1930).—4,2-Cl(1-$C_{10}H_7CO$)-$C_6H_3CO_2H$ and concd. H_2SO_4, heated at 58–60° for 1.5 hrs., give *2-chloro-5,6-benzanthraquinone*, yellow, m. 222–3°; heating with concd. NH_4Cl with a little $CuCl_2$ at 180° for 20 hrs. gives the *2-NH_2 deriv.*, orange-red, m. 283–5°; concd. H_2SO_4 gives a greenish yellow color; the sulfate and HCl salt are light yellow, and may be crystd. from AcOH but are hydrolyzed by H_2O. Heating the NH_2 deriv. with an equiv. amt. of AcOK and 10 parts KOH (added in portions) at 250–70° gives *5,6,5',6'-dibenzo-N,N'-dihydro-1,2-anthraquinonazine*, metallic glistening needles, which gives a blue color in alk. hyposulfite, changing to a brown-violet on further reduction; cotton is colored a dirty greenish blue, changing to a pure blue on treating with dil. AcOH; with air or on heating with a dil. soap soln. a clear bluish green color results. 2,3-$C_{10}H_6(CO)_2O$ and PhCl with $AlCl_3$, heated on the H_2O bath, give *2-(4'-chlorobenzoyl) 3-naphthoic acid*, m. 215–20°; concd. H_2SO_4 gives a deep red color, unchanged at 180°; above this temp. ring closure and sulfonation take place; $ZnCl_2$ and a little AcOH at 200–50° give 2-chloro-6,7-benzanthraquinone, yellow; alk. hyposulfite gives a green color. C. J. WEST

1-Hydroxyphenanthrenequinone. K. BRASS, E. WILLIG AND R. HANSEN. *Ber.* **63B**, 2613–6(1930).—Shortly after the preliminary announcement of the synthesis of 1-hydroxyphenanthrenequinone (I) (*Z. angew. Chem.* **42**, 602(1929)), Fieser (*C. A.* **23**, 4468) described its prepn. from phenanthrenequinone-1-sulfonic acid. B. and his collaborators made it by the Scholl reaction from *o-methoxybenzil* (II) with $AlCl_3$. The corresponding *o-methoxybenzoin* (III) was obtained in 70% yield by mixed acyloin



condensation from BzH and *o*-$MeOC_6H_4CHO$. Since Hörbye (*Diss. Dresden*, 1917) showed that in unsym. substituted benzoins the secondary alc. group is adjacent to the unsubstituted Ph residue, III is assigned the structure $PhCH(OH)COC_6H_4OMe$. Attempts to purify it showed that it consisted of a colorless solid and a yellow liquid form. Attempts to obtain *o*-hydroxybenzoin failed; *o*-$H_2NC_6H_4CHO$ and BzH gave no mixed benzoin. Oxidation of the crude III with alk. $KMnO_4$ yielded 60% pure II. When II is treated with $AlCl_3$, not only is aromatic H split off intermolecularly but dealkylation also occurs and I is obtained, although in only 1% yield. I is dark red, only difficultly sol. in aq. alkali, reacts with pyroboroacetate, forms a black *inner complex salt* with $SnCl_4$ and dyes mordanted fibers violet but the colors are not fast. The 2-, 3- and 4-HO isomers of I dye mordanted cotton only weakly but the colors on wool mordanted with Cr oxide (2-deriv. reddish violet, 3- and 4-derivs. red-brown) are as deep as that produced by I; probably, being stronger acids, they act on wool as acid wool dyes and, moreover, form with the metal oxide ordinary salts which are more stable than the 6-membered secondary valence ring of the inner complex salts of I. III, light orange-yellow oil, b_{16} 235°, and colorless crystals, m. 56–7°, sol. in concd. H_2SO_4 with yellow color turning to green, reduces Fehling soln. in MeOH. II, pale yellow, m. 71–2°, sol. in H_2SO_4 with red color; *2,4-dinitrophenylhydrazone*, yellow, m. 176–7°, sol. in H_2SO_4 with orange-red color; the corresponding *osazone* exists in an orange α-form, m. 227–8°, rearranging into the β-form, red, m. 295°; boiling AcOH produces the same rearrangement. I, m. 218–9°, forms a violet sublimate, dissolves in H_2SO_4 with dark olive-green color, forms a yellow $Na_2S_2O_4$ vat, gives in Ac_2O with pyroboroacetate a violet color changing to yellow-brown on warming. C. A. R.

Unsymmetric *o*-disubstituted benzils and their conversion into analogous phenanthrenequinones. K. Brass and R. Stroebel. *Ber.* **63B**, 2617-21(1930); cf. preceding abstr.—After the synthesis of 1-hydroxyphenanthrenequinone had been effected, the next problem was the synthesis of the difficultly available 3,4-di-HO compd. (morpholquinone (I). Unsym. *o*-substituted benzils are unknown, however, and of the corresponding benzoins only benzopiperoin (II) has been described (Hörbye). The prepn. of II has been improved and its oxidation with Fehling soln. gave *benzopiperil* (III) in good yield *o-Dimethoxybenzil* (IV), however, was obtained in only 13% yield. The benzoin (from 3,4-$(MeO)_2C_6H_3CHO$ and BzH) always contains some of the sym. compd. and oxidation of the product gave a mixt. of IV and the tetra-MeO compd. (14:1), the latter of which can readily be sepd. because of its slight soly. The pure IV exists in a yellow and a colorless form. With $AlCl_3$ it can theoretically give 2,3- or 3,4-dimethoxyphenanthrenequinone or a mixt. of the 2; it actually gave 6% of Pschorr and Buckow's 2,3-di-MeO compd. (V) and the tetra-MeO compd., but the formation of 2,4-dihydroxyphenanthrenequinone (VI) (see following abstr.) was also observed, *i. e.*, there also occurred a partial dealkylation of the benzil, condensation of the resulting dihydroxybenzil to I and rearrangement of the latter. III likewise gave 3–4% of (presumably *2,3-)methylenedioxyphenanthrenequinone* (VII) which, however, could not be dealkylated with even the most energetic reagents (PCl_5). Similarly, all attempts to dealkylate V were unsuccessful. II, obtained in 32% yield from piperonal, BzH and KCN in aq. MeOH, m. 115°. III (70% yield), m. 120°, forms yellow solns. (greenish yellow in concd. H_2SO_4), is stable toward cold 10% alkali, is not hydrolyzed by concd. H_2SO_4, boiling 10% HCl or concd. HI but gives *o*-dihydroxybenzil (see following abstr.) with PCl_5. With $SnCl_4$ in dry C_6H_6 it forms a dark red *mol. compd. 2,4-Dinitrophenylhydrazone*, red, m. 183–4°, sol. in H_2SO_4 with orange-yellow color; *osazone*, m. 270° (decompn.). IV, m. 117.5°, sol. in H_2SO_4 with yellow-green color changing slowly to greenish brown. VII, red-brown, m. 258–9°, sol. in H_2SO_4 with brown-olive color, forms a light yellow vat with alk. $Na_2S_2O_4$. V, dark red, m. 303° (cor.), sol. in H_2SO_4 with deep yellow color, forms a green-yellow vat with alk. $Na_2S_2O_4$. *Tetramethoxyphenanthrenequinone*, from the benzil with $AlCl_3$ in $PhNO_2$ (30% yield), olive-green, m. 258°, forms deep red solns. (red-brown in H_2SO_4). C. A. R.



Action of aluminum chloride on *o*-dihydroxybenzil. K. Brass, F. Luther and K. Schoner. *Ber.* **63B**, 2621-7(1930).—As shown in the preceding abstr. the C_6H_6 nuclei of *o*-dimethoxybenzil and probably also of benzopiperil condense in the Scholl reaction in such a way as to yield 2,3-dimethoxy- or 2,3-methylenedioxyphenanthrenequinone. It was thought that possibly in *o-dihydroxybenzil* (*2,3-, 3,4-* or *m,p-dihydroxybenzil*) (I), with its free HO groups, the loosening action of the $AlCl_3$ would extend to other H atoms and lead to the formation of morpholquinone (3,4-dihydroxyphenanthrenequinone) (II). At first, all attempts to bring about a reaction between I and $AlCl_3$ failed and it was only by using $PhNO_2$ at 100° and heating a short time to

160° that there was obtained 25% of a compd. (III) having the compn. of a dihydroxyphenanthrenequinone but which was neither II nor the 2,3-compd. It greatly resembled II, to be sure, but differed from it in that the cherry-red soln. of its diacetate in NaOH-MeOH soon turned olive-green, while that of the diacetate of II becomes deep blue. Moreover, the III itself dissolves in alkali with olive-green color while II gives a deep blue and the 2,3-di-HO compd. a red-violet soln. III in Ac_2O is unchanged by pyroboroacetate, indicating the absence of a 1-HO group and thus excluding 7 of the 16 possible dihydroxyphenanthrenequinones. Further, oxidation gave o-$C_6H_4(CO_2H)_2$, showing that the two HO groups are in the same nucleus, thus excluding 6 more of the possible isomers, and, since II and the 2,3-compd. are also excluded, leaving only the structure of *2,4-dihydroxyphenanthrenequinone* for III. The reaction, therefore, has resulted not only in ring closure to a phenanthrenequinone but also in migration of one of the HO groups. Among the products were also found some unchanged I and a very small amount of II. The Scholl reaction, therefore, possibly gives II primarily which then rearranges into III; unfortunately, not enough II was available to test this point. III is characterized by its soly. in many solvents and the intense red color of the solns. It possesses dyeing properties, probably because of its acid nature. The I was obtained in 57% yield from benzopiperil with PCl_5; it exists in a colorless and a yellow form and is characterized by its soly. and the intense yellow color of its solns.; aq. solns of a certain concn. have a colloidal character. All attempts to synthesize II have failed, and the best way for its prepn. would still seem to be to start from codeine (or methylmorphimethine) or from morphine. The small quantity of pure II finally obtained from acetylmethylmorpholquinone formed a red powder which did not suffice for prepn. in analytically pure form. It did not melt and darkened at 300° with formation of a violet sublimate. It dissolved in H_2SO_4 with brown-red color and the yellow soln. in Ac_2O gave a red-violet color on addn of pyroborate and on heating. With $SnCl_4$ it forms a complex (deep blue soln.), also with $AlCl_3$ in $PhNO_2$ (blue ppt.). Of the colors formed with metallic oxide mordants, the deep violet color with Sn mordants is the most beautiful, but they are not fast. I, m. 157.5°, soly. in boiling H_2O 1.24 : 100, seps. from Et_2O and C_6H_6 in yellow crystals, dissolves in alkalies with red-yellow, in H_2SO_4 with lemon-yellow color, gives a deep green color with aq. $FeCl_3$, cannot be acetylated but readily yields a light yellow *dibenzoate*, m. 98.5 9.5°, and is methylated to the di-MeO compd., m 114 5°. Cl in AcOH gives a *di-Cl deriv.*, m 189-90° III, dark-brown needles, red in incident light, decomps. 240°, m above 300°, dissolves in dil. alkalies with olive-green, in H_2SO_4 with olive-yellow color, gives a dark-brown color with aq. or alc. $FeCl_3$, forms with 3,4-$(H_2N)_2C_6H_3Me$ in boiling AcOH a *quinoxaline* whose almost colorless *diacetate* m. 219° and dissolves in H_2SO_4 with violet-red color *Diacetate* of III, brown-yellow crystals with golden luster, m. 197-8°, mol wt. in camphor 322-29.8. C. A. R.

Fluoranthene and its derivatives. II. Julius v Braun and Gottfried Manz *Ber.* **63B**, 2608 12(1930); cf. *C. A.* **23**, 2713. —The formula (I) recently established,

(I)

(VI)

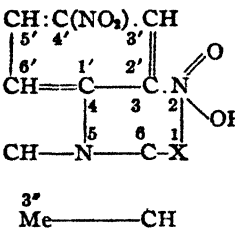
by synthesis, for fluoranthene opened up the possibility of easily carrying out numerous transformations with I. A study of these transformations on a broad basis has been undertaken, and in this paper are described the substances which can be obtained by its more or less exhaustive hydrogenation. Goldschmiedt with Na-Hg and with HI under not too vigorous conditions had obtained a dihydro compd., $C_{15}H_{12}$, m. 76°, and by more energetic treatment with HI a liquid $C_{15}H_{18}$. Repetition of the latter part of his work showed that HI at temps. above 200° gives a mixt. of hydrogenated derivs. which cannot be sepd. by distn., whereas Na-Hg at 180° gives almost quantitatively 1,2,3,4-tetrahydrofluoranthene (II), m. 75°, identical with the product which had been synthesized in the prepn. of I. Its exclusive formation under these conditions shows that one-half of the $C_{10}H_8$ complex in I is more readily hydrogenated than the C_6H_6 nucleus 4. A dihydro deriv. is probably an intermediate product but it has thus far not been possible to demonstrate its formation; Na and moist ether or H activated

by Pt or Pd have no appreciable action on I at room temp., and under pressure II is the 1st product which can be isolated. If somewhat less than 10 atoms H is used the product chiefly contains, in addn. to **II**, *1,2,3,4,9,10,11,12,13,14-decahydrofluoranthene* (**III**); with more than 10 atoms H, II disappears and a little *perhydrofluoranthene* (**IV**) is formed. **III** can be sepd. from the IV by sulfonation and cleavage of the SO_3H acid and on rehydrogenation under pressure gives **IV** quantitatively. **III**, also formed from I and II with Na and alc., gives 1,2,3-$C_6H_3(CO_2H)_3$ on oxidation and, like **II**, regenerates I when dehydrogenated with PbO; a partial dehydrogenation to the *9,10,11,12,13,14-hexahydrofluoranthene* (**V**) could not be detected, even when it was attempted to substitute two Br atoms alicyclically in III and then split off 2 mols. HBr. Nor could V be found along with II or the decahydro compd. **VI** along with its isomer III among the hydrogenation products. In short, I is first hydrogenated in ring 2, then 4 and finally 1. **III**, b_{12} 181-3°, d_4^{22} 1.043, does not solidify in ice-salt, is stable toward atm. O. **IV**, b_{12} 168 70°, d_4^{22} 0.9811. **II**, m. 74-5° after crystn. from alc., b_{12} 203-5°, forms no picrate. C. A. R.

Homochromanone. S. G. Powell and Lucile Anderson *J. Am. Chem. Soc.* **53**, 811(1931).—$PhOCH_2CH_2CH_2CO_2H$ and P_2O_5 in C_6H_6 give a poor yield of homochromanone, obtained as a lemon-yellow oil; the *semicarbazone* m. 228-9°, and the *oxime* m. 99°. C. J. West

Utilization of agricultural wastes. Henry Gilman, R. E. Brown, J. B. Dickey, A. P. Hewlett and G. F. Wright *Proc. Iowa Acad. Sci.* **36**, 265-6(1929).—The *syn-* and *anti*-oximes of δ-benzylfurfural have been examd. in connection with sweet tasting compds. The *syn-* is sweeter than the *anti*-compd. and also sweeter than saccharin. δ-Bromofurfural has been prepd. by the bromination of furfural diacetate. Organometallic compds. and derivs. from them have been prepd. from 1-tetrahydrofuryl-3-bromobutane. Tetrahydrofuryl *p*-toluenesulfonate has been prepd. and tested for its alkylating action. A series of halogen furoic and furylacrylic acids has been prepd. in antiseptic studies, and their Hg and Cu salts are being tested for their possible applications as *fungicides*. W. G. Gaessler

Spectrochemistry of furan and its derivatives. Everett C. Hughes and John R. Johnson *J. Am. Chem. Soc.* **53**, 737-46(1931).—The d. and *n* (in the visible region of the spectrum) are given for furan, 2-methylfuran, furfuryl alc., furfuryl acetate, Et furylpropionate, furylbutanone, furylpentanone, 2-chlorofuran, 3-chlorofuran, 2-bromofuran, 3-bromofuran, 2-methyl-3-carbethoxyfuran, Et furoate, Et 5-chlorofuroate, Et 3-chlorofuroate, furyl cyanide, furylethylene, furylbutenone, furylpentenone, Et furylacrylate and furfural pinacolone. The absorption spectra are reported for furylethylene, Et furylacrylate, furylbutenone, 2-furoic acid and its 5- and 3-Cl derivs. and 2-methyl-3-furoic acid. From the mol. refractions and the exaltations of the dispersion, calcd. from these data, the furan derivs. are divided into 2 classes: 1 in which the value *E*MR is neg., including furan and all of the derivs. in which the substituents do not contain a double bond on the atom immediately attached to the ring, in the α-position; and a 2nd, in which this value is pos., including all of the derivs. in which the side chain contains a double bond forming a conjugated system with the ring. Isomeric α- and β-substituted furan derivs. may be distinguished from each other by spectrochem. means, the exaltations of the dispersions for the α-isomers being envariably higher than for the β-isomers. For 5 furan derivs. (furylethylene, furylbutenone, furylpentenone, Et furylacrylate and furfural pinacolone) the wave lengths of the absorption max. (in the near ultra-violet) calcd. from the Sellmeir dispersion formula are in agreement with the wave lengths of the absorption max. actually observed. Electronic formulas for the furan ring have been proposed and discussed from the standpoint of interpretation of reactions of furan derivs. C. J. West



Coumaryl-2-aldehyde and a few other coumarone derivatives. Tadeus Reichstein and Ignaz Reichstein. *Helv. Chim. Acta* **13**, 1275-81(1930).—*Coumarilyl acid cyanide* (**I**), RCOCN (R = O C_6H_4.CH:C—) (42 g.), was prepd. from 54 g. of the

chloride (**II**), RCOCl, in dry Et_2O with 23 g. dry HCN. **II**, b_{14} about 130°, was prepd. from 50 g. coumarilic acid refluxed with excess $SOCl_2$ and the product distd. *in vacuo*. I b_{11} about 115°; recrystd. from C_6H_6, it m. 100-1°. I breaks up in the presence of H_2O into coumarilic acid and HCN. Boiled with EtOH the Et ester is formed, m. 29-30°. I (20 g.), shaken 1 week with 120 cc. concd. H_2SO_4, gave a mixt. of *coumaroylformic acid* (**III**), $RCOCO_2H$, and its *amide* (**IV**). A NaOH soln. of the mixt. extd. with Et_2O gave in the NaOH soln. **III**, m. 153°, and in the Et_2O soln. **IV** which, recrystd. from water, m. 187-8°. In the presence of alkali IV is easily converted into III. III

distd. in a high vacuum and recrystd. from toluene gave pale yellow plates, m. 157–8°. III (10 g.), boiled 10 min. with 25 g. $PhNH_2$, cooled, acidified with 60 cc. concd. HCl and extd. with Et_2O, and the ext. distd. *in vacuo*, gave 3.5 g. (45.6% yield) *coumarilaldehyde* (V), RCHO, b_1 90–100°. Purified with $NaHSO_3$, V was obtained colorless, b_{13} 130–1°, m. 9–9.5°; *semicarbazone*, m. 245–6°; *phenylhydrazone*, m. 136–8°; *β-naphthylamide*, m. 116.5–8°. The $NaHSO_3$ compd. gave the cyanohydrin, m. 66.5–68°. I reduced with Zn dust in HOAc gave the semicarbazone in 42% yield. V, oxidized with Ag_2O in alk. soln., gave coumarilic acid, m. 197–8°. V, shaken in KOH soln., satd. with CO_2, extd. with Et_2O and shaken with $NaHSO_3$, gave *coumarylcarbinol* (VI), RCH_2OH, an oil, b_1 105–10°, which crystd. and m. about 26°. The *p-nitrobenzoate* m. 145–6°. III in EtOH, heated with $N_2H_4.H_2O$ and EtONa, the product boiled with animal charcoal and distd. *in vacuo*, gave *coumarylacetic acid* (VII), RCH_2CO_2H, recrystd. from C_6H_6, m. 98–9°. RACHEL BROWN

Constitution of the complex metal compounds of indigo (preliminary communication). K. KUNZ. *Ber.* **63B**, 2600(1930).—Several papers have appeared in recent years which do not agree with K.'s conception of a purely complex union of the metal in the metal compds. of indigo (cf., among others, Machemer, *C. A.* **25**, 102). K. has no new exptl. material of his own in this field, and the papers referred to make the formation and compn. of the compds. appear in a new light. K. intends again to take up the question experimentally and to resume the study of the action of Fe carbonyl on indigo. C. A. R.

***aci*-Form of 1-*m*-dinitrophenyl-3-methyl-5-hydroxypyrazole and its amino and thio analogs.** C. A. ROJAHN AND HEINZ FEGELER. *Ber.* **63B**, 2510–19(1930).—While the Cl in 1-phenyl-3-methyl-5-chloropyrazole is firmly held, like the "atomatically bound" Cl in PhCl, NO_2 groups on the 1-Ph nucleus labilize the Cl to a remarkable degree, so that it can be removed from 1-*m*-dinitrophenyl-3-methyl-5-chloropyrazole (I) in the cold, like aliphatically bound Cl, by the most varied basic reagents. KOH in MeOH (EtOH, BuOH) gives 3 Cl-free products: one colorless (II), one red (III) and one yellow (IV). II and IV are readily isolated in pure form, but III is very sensitive and quickly changes into IV. II is the alkyl ether of the 5-hydroxypyrazole while III and IV are K salts sol. in H_2O, the soln. giving ppts. with heavy metals and, on acidification, a colorless compd. of pronounced acid character which is believed to have the structure

(V, X = O). In agreement with this structure are the facts that 2 atoms K are necessary for the formation of III and IV, V gives no green NO compd. with HNO_2 and no 5-chloropyrazole with $POCl_3$, and the corresponding NH_3, $PhNH_2$ and $PhNHNH_2$ derivs. (V, X = NH, NPh, etc.) likewise form salts and always yield V with hot alkali. KSH in alc. also yields a colorless thio ether analogous to II and red and yellow salts of V (X = S). *1-m-Dinitrophenyl-3-methyl-5-methoxypyrazole* (II), m. 182°. *5-EtO homolog*, m. 112°. *5-BuO compd.*, m. 99°, changes into the 5-EtO compd. on repeated crystn. from EtOH. *K salt* (IV) of (*4'-nitrobenzo*)-(*2',1':3,4*)-(*3''-methylpyrazolo*)-(*1'',5'':5,6*)-*N*²-*hydroxy*-*N*²-*oxoöxdiazine-1,2,5* (V, X = O), does not m. 350°; free V, m. 126°, decomps. below 100° (evolution of NO) *in vacuo*. *N*¹-*Phenyl*-*N*²-*hydroxy*-*N*²-*oxotriazine-1,2,5 analog* (V, X = NPh), from I and $PhNH_2$ in xylene, yellow, m. 190° (in 1 expt. an *isomer*, m. 156°, changing to 190° after some time, was also obtained), dissolves with red color in alc. KOH on gentle warming and is repptd. unchanged by acids, but if it is heated some time with alc. or aq. alkali it changes into IV; Sn and concd. HCl reduce it to *1-m-diaminophenyl-3-methyl-5-phenylaminopyrazole*, m. 184° (*di-HCl salt*, begins to sublime about 200°, m. 242°). *N*²-*Hydroxy*-*N*²-*oxotriazine-1,2,5* (V, X = NH), from I and alc. NH_3 at 140°, red and yellow crystals changing on standing or recrystn. into the yellow form, m. 204°, forms no picrate, HCl salt, Ac or Bz deriv. *N*¹-*p-Tolyl deriv.* (V, X = NC_6H_4Me), from I and *p*-$MeC_6H_4NH_2$ in xylene, yellow, m. 166°. *N*¹-*Formyl compd.* (V, X = NCHO), from I and $HCONH_2$ in xylene, egg-yellow, m. 286°. *N*¹-*Phenylamino compd.* (V, X = NNHPh), from I and $PhNHNH_2$ in boiling PhMe, lemon-yellow, m. 216° (de-

compn.), also obtained at room temp. from V (X = O) and $PhNHNH_2$. Attempts to benzoylate V (X = O) in C_5H_5N gave a yellow *pyridine compd.* $C_{15}H_{13}O_5N_5$, m. 226° (decompn.), loses C_5H_5N and forms the K salt of V with hot KOH. *1-m-Dinitrophenyl-3-methyl-5-cyanopyrazole*, obtained in small amt. (together with much IV) from I and alc. KCN, m. 169°, insol. in dil. alkali but converted by boiling alkali into IV. *5-p-Toluenesulfonyl compd.*, from I and *p*-$MeC_6H_4SO_2Na$ in dil. alc., m. 219°. *5-Ethylmercapto compd.*, yellow, m. 259°; *K salt* of *aci*-form (V, X = S), deep red; free acid, *(4'-nitrobenzo)-(2',1':3,4)-(3"-methylpyrazolo)-(1",5":5,6) - N^2 - hydroxy - N^2 - oxothiodiazine-1,2,5*, yellowish, m. 179°. C. A. R.

Polymerization product of ring-forming amino acids. E. MIYAMICHI. *J. Pharm. Soc. Japan* **50**, 1100–3(1930); German abstr. 146.—*2-Phenyl-5-glyoxalone* (m. 141°) was treated with glycerol (about 8–10 times) and $Ba(OH)_2$ as polymerizing agent at 120–5° for 2 hrs. The product was obtained in colloidal form by adding water to the cooled reaction mixt. It gave the characteristic reactions of natural proteins. *2-Phenyl-4-(glycocollethylamidimido)benzyl-5-ethylimidoöxazoline* (m. 143°), *2-phenyl-5-ethoxyoxazole* (b_{12} 150–2°), and *2-phenyl-5-ethoxythiazole* (b_{12} 137–40°) were treated as above at 180°, 155–60° and 140°, resp., and the products obtained gave the characteristic reactions of natural proteins. F. I. NAKAMURA

Synthesis of *l*-2-thiolhistidine. JULIUS N. ASHLEY AND CHARLES R. HARINGTON. *J. Chem. Soc.* **1930**, 2586–90.—In connection with the search for *2-thiolhistidine* (I) among the products of hydrolysis of zein and other proteins, the following synthesis was carried out. Histidine was converted into the Me ester di-HCl salt; BzCl gives Me α,γ,δ-tribenzamido-Δ$^\gamma$-pentenoate, transformed by MeOH-HCl into Me α,δ-dibenzamido-γ-ketovalerate, which, boiled with 20% HCl for 1.5 hrs., gives *α,δ-diamino-γ-ketovaleric acid-di-HCl*, which could not be obtained cryst. but with NaSCN, on heating 1 hr., there results I, darkens 290°, does not m. 310°, $[\alpha]_{5461}$ —9.5° (*c* 2.01 in *N* HCl); I gives the ninhydrin reaction; aq. I decolorizes alk. $KMnO_4$ in the cold; on warming with $FeCl_3$, H_2SO_4 is liberated; evapn. with concd. HCl gives the *di-HCl salt*, m. 197–9° (decompn.); *monopicrate*, orange-red, m. 156°; I is pptd. from H_2O by Ag salts at p_H 5, by $HgSO_4$ in 5% H_2SO_4 and by $HgCl_2$ in faintly acid soln. Oxidation with $Fe_2(SO_4)_3$ gives histidine. C. J. WEST

Action of nitric acid on acetylene. III. A. QUILICO AND M. FRERI. *Gazz. chim. ital.* **60**, 721–44(1930).—After having established the constitution of α-isoxazolecarboxylic acid (I) (cf. *C. A.* 24, 3484) and of α,β'-diisoxazolyl ketone (cf. *C. A.* 24, 3788), a study was begun of the other more complex products of the reaction of C_2H_2 and fuming HNO_3, particularly of the explosive compd. $C_4H_2N_6O_7$ (II) and its decompn. product $C_4H_2N_4O_3$ (III). Great difficulties were encountered, both because of the low yields and because of the behavior of the products, which, in general, are very resistant toward reagents, and when finally attacked, form too simple decompn. products. The present paper partly completes the investigation. Under the conditions already described (*C. A.* 24, 3484) which give the highest yield of I, only a small yield of II is obtained. A higher yield of II is obtained in the following way. Fuming HNO_3 (180–200 cc. of d. 1.48) divided in 2 Lunge tubes in series treated with a current of C_2H_2 (washed with $NaHSO_3$) for 3–4 days (until the reaction mixt. passes from brown-red to green-yellow), poured into cold water (800 cc.), let stand several hrs., filtered, the residue washed with cold water, and dried *in vacuo* over P_2O_5 and KOH, yields 1.8–2.5 g. of II. Thus prepd., II is straw-yellow, m. around 78° (decompn.). II is so unstable that it is very difficult to recrystallize it from AcMe or glacial AcOH. It gives yellow solns. in cold aq. 10% alkalies and red-orange solns. in alc. KOH and in alc. KOEt. When its soln. in 10% NaOH is boiled, NH_3 is evolved. In EtOH, II gives with $PhNH_2$ a dark green soln., which then becomes blood-red and finally brown and by evapn. yields a pitchy *substance*. Boiled with water or dil. mineral acids, II decomps. and on cooling a cryst. *compd.* (IV), m. 108°, seps. (see later). Colorless solns. are obtained with $SnCl_2$, Zn + AcOH, etc., whereas with Na-Hg and water intense orange-yellow solns. are formed, as a result of the formation of the compd. $C_4H_6N_6O_3$ (V) (see later). In boiling water, II decomps. and the soln. contains HNO_3. II (4 g.), added slowly, with vigorous agitation, to $SnCl_2$ (40 g.) in concd. HCl (40 cc.) (keeping cool), let stand several hrs. at room temp. in contact with granulated Sn (to reduce $SnCl_4$ to $SnCl_2$), dild. with boiling water (1000 cc.), the Sn pptd. with H_2S, filtered, the filtrate concd. to a small vol., let stand *in vacuo* over KOH until crystn. is complete, filtered and dried on a porous plate, yields 1.5–2.0 g. of crude product, which after purification with animal charcoal and recrystn. from water contg. a trace of HCl, gives *oxyamidoöxime-HCl*, $(C_3H_4N_6O)C(:NOH)NHOH.HCl$ (VI), decomps. around 182°, is very stable in air and in acid soln.; in water it gives with $FeCl_3$ a dark blue-

green color, and with excess $FeCl_3$ a flocculent ppt. of the same color seps. With $AgNO_3$ **VI** ppts. a yellowish *substance* mixed with AgCl, which slowly becomes black. With $Cu(OAc)_2$ **VI** ppts. a brown-black *substance*, insol. in AcOH, sol. in HCl. With acidic KI, **VI** liberates I. The mother liquor from the prepn. of **VI** yields $HONH_3Cl$. With alkalies, aq. **VI** gives intense orange-yellow solns. which become of a lighter color on addn. of mineral acids. The same phenomenon occurs with NH_4OH, Na_2CO_3 and $NaHCO_3$ but not with NaOAc. Ice-cold aq. **VI** (2 g. in 2–3 cc.), made alk. with 50% KOH, acidified with glacial AcOH, the ppt. washed with water and recrystd. from boiling water, yields the *compd.* $C_4H_5N_5O_2$ (**VII**), yellow, m. 185–90° (decompn.), in water with $AgNO_3$ ppts. a brick-red *compd.*, with aq. $FeCl_3$ gives a brown-red color, gives intense orange-yellow solns. in aq. alkalies and alk. carbonates (repptd. by neutralization) which on boiling become brown-yellow and evolve NH_3. When yellow solns. of **VII** in concd. HCl are boiled and dild. with water, an unidentified *compd.* is ppt. With BzCl in aq. NaOH or Na_2CO_3, **VII** gives a *Bz deriv.*, $(C_4H_4N_5O_2)Bz$ (**VIII**), light yellow, m. 218° (decompn.). **VIII** is also formed from BzCl and aq. **VII** contg. NaOAc. When **II** is heated in petr. ether the product is **III**, which has the compn. $O_2NCH_2\overset{\frown}{C}:N.O.N:\overset{\frown}{C}CN$, mixed with pitchy substances and an oil $C_{12}H_{22}N_2O_5$ (cf *Gazz. chim. ital.* **32**, 202(1902)). When carried out in AcOH, the decompn. leads to a better yield and without secondary products. **II** (5 g.) in glacial AcOH (30 cc.), heated (at first cautiously) until decomp. is complete, and then more actively until most of the AcOH is evapd., dild. with water (4–5 vols.), filtered, washed with cold water and the residue recrystd. from EtOH or C_6H_6, yields 90% of **IV**, $C_4H_2N_4O_3$, m. 108°, sol. in warm concd. H_2SO_4 (addn. of a trace of PhOH to this soln. gives a green color), gives no color with $FeCl_3$, does not react with $PhHNNH_2$, does not react with boiling $SOCl_2$, reacts easily with alkalies; in cold 10% KOH it gives with $NaNO_2$ and H_2SO_4 an orange-red color, very stable toward oxidizing agents, partially decompd. to CO_2, HCN and N by $KMnO_4$ in H_2SO_4. **IV** (3 g.), added slowly (with cooling) to $SnCl_2\ 2H_2O$ (14 g.) in concd. HCl (14 cc.), let stand several hrs. with granular Zn, dild. with boiling water (500 cc.), the Sn eliminated with H_2S, filtered, evapd. to a small vol., cooled, filtered, the residue (2 g.) dried on a porous plate and purified with animal charcoal and recrystd. from water, yields *furazanmethylamine-HCl*, $C_3H_6N_3OCl$, probably $\overset{\frown}{CH}:N.O.N:\overset{\frown}{C}CH_2NH_3Cl$ (**IX**), m. around 185° (decompn.), has strong reducing powers, with aq. H_2PtCl_6 turns green and ppts. Pt black, gives with aq. $AgNO_3$ a Ag mirror at room temp., with $Cu(OAc)_2$ ppts. a brown-black substance, difficultly sol. in AcOH but sol. in HCl, does not give any color with $FeCl_3$ (though the $FeCl_3$ is reduced to $FeCl_2$). N is evolved in all these reductions. Cryst. AcONa and a little BzH, added to **IX** in 50% AcOH, heated on a water bath for 0.25 hr., cooled and the ppt. recrystd. from EtOH, yield the condensation *compd.* $C_{10}H_9N_3O$, m. 154°, behaves like a Schiff base, with boiling HCl forms **IX** and BzH. $NaNO_2$ (0.4 g.), added to aq. **IX** (0.5 g.), evolves N and forms a light yellow *oil* with intense sweet odor like that of dimethylfurazan. On steam distn. the oil is obtained in colorless form, but in too small yield to identify. It is probably an *alc.* $C_3H_3N_2OH$ corresponding to the primary amine. By the Schotten-Baumann method in NaOH soln., a Bz deriv. does not sep. in the reaction of **IX** with BzCl, but in $NaHCO_3$ soln. a ppt. is obtained immediately and on recrystn. from hot EtOH this yields a *mono-Bz deriv.* of **IX**, $C_{10}H_9N_3O_2$, m. 198° (decompn.), sol. in dil. alkalies. **IX**, boiled 1 hr. with Ac_2O and AcONa, dild. with water, filtered, the residue washed with water and recrystd. from EtOH (with animal charcoal), yields a *tri-Ac deriv.* of **IX**, $C_9H_{11}N_3O_4$, m. 75°. It is probable that Ac_2O reacts in some complicated way, with secondary reactions. From **IX** dissolved in 50% KOH the *free base* $C_3H_5N_3O$ seps. as an oil, very unstable, turns brown from decompn. when left overnight in the KOH soln. **IV** is very stable toward acids, but when heated in a closed tube with concd. HCl (1 g. of **IV** in 20 cc.) for 2 hrs. at 140°, evapd. *in vacuo* over KOH to remove HCl, the residual oil dild. with a little water, extd. with Et_2O, the ext. evapd., leaves an *oil* (**X**) with sweet odor, heavier than water, does not contain Cl. The aq. liquor contains considerable NH_4Cl but no $(CO_2H)_2$ or NH_2OH. The NH_4Cl probably results from the sapon. of a CN group and the CO_2 evolved by elimination of the CO_2H formed in this sapon. **X** is probably *nitromethylfurazan*, $\overset{\frown}{CH}:N.O.N:\overset{\frown}{C}CH_2NO_2$, corresponding to the amine $C_3H_5N_3O$. **IV**, refluxed with concd. HCl, evolves CO_2, with formation of NH_4Cl and **X**. To establish by esterification the CO_2H group which is so easily eliminated, the action of alc. HCl was tested. **IV** (1.8 g.) and abs. EtOH (40 cc.), satd. with HCl in a sealed tube, heated 1 hr. at 120–30° (EtCl and CO_2 are

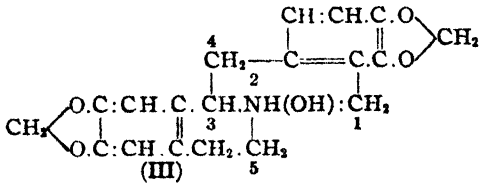
liberated), evapd. on a water bath to remove most of the EtOH, dild. with water, extd. with Et_2O, the ext. dried over $CaCl_2$, distd., the residue freed of oil on a porous plate and recrystd. from EtOH + C_6H_6, yield the *compd.* $C_4H_6N_2O_2$ (or $C_6H_9N_3O_3$), m. 124°, neutral, decomps. above its m. p. with evolution of white fumes and a HCN odor and with considerable carbonization, is insol. in alk. carbonates, reduces $KMnO_4$ in aq. alkalies. A study of the action of aq. and alc. alkalies on **IV**, both of which attack it easily, is still unfinished, but a few preliminary results are reported. **IV** (2 g.), mixed with 50% KOH (20 cc.), evolves heat, becomes violet-red, acquires a characteristic sweet odor and forms an oil emulsion. When heated gently, the liquid becomes clear red, contains K_2CO_3 and the yellow oil seps. The oil is **X**, and is formed by elimination of CO_2 from the acid resulting from sapon. of the CN group of **IV**. The alk. liquor (after sepn. of **X**), refluxed 0.5 hr. (NH_3 is evolved), the orange liquid concd. on a water bath, the K_2CO_3 which seps. filtered off and the filtrate evapd., yields an unidentified *K salt*, carbonizes when heated; its aq soln. gives with $FeCl_3$ an intense red color which vanishes when acidified. It is probably a K salt of a NO_2 acid. **IV** (2 g.), added slowly to 25% KOH in MeOH (25 cc.), the red soln. heated cautiously for 0.5 hr., filtered, the residue washed with MeOH, the filtrate evapd. to obtain more salt and the combined residues dried, yields a *salt* (**XI**) which is probably that of a CO_2H acid; its aq. soln. acidified with AcOH gives with $AgNO_3$ a yellow *Ag salt* which when dry explodes upon being heated. Aq **XI**, acidified with dil. H_2SO_4, evolves CO_2 and yields a turbid liquid which, extd. with Et_2O, the ext. evapd. and the residue recrystd. from boiling water, yields a *compd.* with pearly aspect, m 163.5° (decompn.). Its quantity was too small for analysis, but it is probably a CO_2H acid. In water it is acid to litmus and it decomps. alk. carbonates. Heated above its m. p., it evolves CO_2. The expts. suggest that the constitution of **II** is $HON{:}C(NO_2)\overset{O}{\overset{\frown}{C}}{\cdot}N\ O\ N\ \overset{O}{\overset{\frown}{C}}C(NO_2){:}NOH$ or $HON{:}C(ON\ O)\overset{O}{\overset{\frown}{C}}{\cdot}N\ O\ N{\cdot}\overset{O}{\overset{\frown}{C}}C(NO_2){\cdot}NOH$, and that it is formed from C_2H_2 thus: $C_2H_2 \xrightarrow{HNO_3} O_2NCH_2CHO \xrightarrow{HNO_2} HON{:}C(NO_2)CHO \xrightarrow{HNO_2} HON{\cdot}C(NO_2)C(:NOH)H \xrightarrow{-H_2O} HON\overset{O}{\overset{\frown}{C}}(NO_2)CN \longrightarrow HON{\cdot}C(NO_2)CNO + 2HON{:}C(NO_2)CNO \longrightarrow HON{\cdot}C(NO_2)\overset{O}{\overset{\frown}{C}}{\cdot}N{\cdot}O\ N(O){:}\overset{O}{\overset{\frown}{C}}(NOH)NO_2 \longrightarrow$ **II** + O. This is rendered probable by the expts of Wieland on nitrile oxides and their polymerization products. C. C. DAVIS

Amino-1-methylbenzoxazoles and their conversion into the arsonic acids of *o*-aminophenol. MONTAGUE A. PHILLIPS *J. Chem. Soc.* **1930**, 2685-90.—1-Methylbenzoxazole is obtained in 15% yield from *o*-$AcNHC_6H_4OH$ and 5 *N* HCl by heating 40 min. at 90° or by the action of 2 *N* NaOH at 90° for 1 hr.; Et_2O-HCl in Ac_2O gives the *HCl salt*, prisms, readily hydrolyzed by cold H_2O. The NO_2 derivs were obtained in 60-80% yields by distg. at 10-20 mm. the corresponding nitroacetyl- or -diacetylaminophenols. The *3-NO_2 deriv.*, pale yellow from Ac_2O, m. 125°; *4-NO_2 deriv.*, m. 154° (*HCl salt*, readily dissocd. by H_2O); 5-NO_2 deriv., m. 151°, also gives a *HCl salt* readily hydrolyzed by H_2O; the *6-NO_2 deriv.*, b_{18} 240-50°, m. 112°; it may be recrystd. from 30% AcOH. The NH_2 derivs. were obtained by reduction with Fe in boiling 10% AcOH; *3-NH_2 deriv.*, m. 67° (*Ac deriv.*, m. 218°); *4-NH_2 deriv.*, b_{20} 160-70°, m. 77-8°; *di-HCl salt*, readily sol. in H_2O; *Ac deriv.*, m. 205° (soly. 1 part in 90 parts boiling H_2O); the *5-acetamido deriv.*, m. 120°, forms a *dihydrate*, m. 83°. The *6-NH_2 deriv.* m. 106° (soly. 1 part in 100 parts boiling H_2O); *Ac deriv.*, m. 145-6°. 5,2-$H_2N(AcNH)C_6H_3OH$ gives a *HCl salt* with concd. HCl. *5-Nitro-2-carbethoxyaminophenol*, yellow, m. 170°; *5-NH_2 deriv.*, m. 129° (*Ac deriv.*, m. 233°). Application of the Bart reaction to the above NH_2 derivs. gives the corresponding acetamidohydroxyphenylarsonic acids. *4-Carbethoxyamino-3-hydroxyphenylarsonic acid*, hexagonal prisms; hydrolysis gives 80% of the 4-NH_2 deriv. C. J. WEST

Pseudo bases in the isoxazole series. IV. E. P. KOHLER AND W. F. BRUCE. *J. Am. Chem. Soc.* **53**, 644-51(1931); cf. *C. A.* **25**, 514.—When the salts that are obtained by alkylating 3-phenylbenzisoxazole are treated with bases they yield a pseudo base, which readily loses H_2O and passes into an anhydro compd.; this is a metoxazine deriv. Since the anhydro compd. can be formed only from a pseudo base which has the HO group in the 3-position, its formation shows that in the rearrangement from a base to a pseudo base the HO group may enter this position when the hindrance to every other type of rearrangement is sufficiently great. Phenylbenzisoxazole is ethylated less readily than those previously studied; the Et deriv. was isolated as the *$FeCl_3$ salt*, $C_{18}H_{14}ONCl_4Fe$, pale yellow, m. 134° (87% yield); *chloride*, m. 95-7°, very hygro-

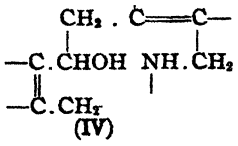
scopic; *$HgCl_2$ salt*, m. 119–20°; *picrate*, yellow, m. 132–3°; *perchlorate*, m. 183–4°. The *pseudo base*, BzC_6H_4ONHEt, results by digesting the ethylation mixt. with HCl and extg. with Et_2O; it m. 79–80° and slowly changes to the anhydro deriv. at room temp., but appears to be stable at —10° for over a year. The Me ether could not be prepd. $NH_2OH.HCl$ and KOH give the *oxime*, $EtHNOC_6H_4CPh{:}NOH$, m. 135.6° (decompn.); with HCl and $FeCl_3$ it gives the above salt, m. 133–4°. PhNCO in C_6H_6 gives the *urea deriv.*, $BzC_6H_4ONEtCONHPh$, m. 128° (*oxime*, m. 145–50° (decompn.)). Heating the pseudo base at 95° *in vacuo* gives the *anhydro compd.*, $C_6H_4.CPh{:}N.CHMe.O$,

m. 33–5°, b_{11} 175–7°; *HCl deriv.*, pale yellow, m. 104°, decomps. slowly at 110°; the H_2O soln. soon deposits the anhydro compd. as a yellow oil; *$FeCl_3$ salt*, yellow, m. 139–40°; *picrate*, bright yellow, m. 128–9°; *$HgCl_2$ salt*, yellow, m. 180–1°. Hydrolysis gives NH_2, AcH and *o*-HOC_6H_4Bz; it is also easily cleaved by $PhNHNH_2$. The anhydro compd. is methylated in the usual manner but the resulting salts are extremely unstable. The *$FeCl_3$ salt* of the *Me deriv.*, $C_{16}H_{16}ONCl_4Fe$, deep yellow, m. 119–20°; hydrolysis gives *o*-HOC_6H_4Bz, AcH and $MeNH_2$. C. J. West



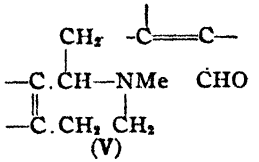
Thiazoles. XVI. Synthesis and study of new aminotoluthiazoles and derivatives from 2,5-diaminotoluene-4-thiosulfuric acid. Marston T. Bogert and Manasseh G. Sevag. *J. Am. Chem. Soc.* 53, 660–9(1931); cf. *C. A.* 23, 5184.—2,5-$(H_2N)_2C_6H_3Me$, $Na_2S_2O_3$ and $AlCl_3$ give 15% of *2,5-diaminotoluene-4-thiosulfuric acid* (I); a potentiometric titration shows its ionization const. to be 5.56×10^{-6} at 25°. In the course of the titration, it was noticed that, after reaching a certain stage in the expt., the potential began to drop to a final equil. much lower than the initial one; this phenomenon occurred only within the range p_H 7.66–9.58 and may be due to occlusion of acids. Refluxing I and *o*-$O_2NC_6H_4CHO$ in glacial AcOH for 20–30 min and then more strongly for 1 hr. gives 36% of *2-(o-nitrophenyl)-5-methyl-6-aminobenzothiazole* (II), yellow, m. 144° (all m. ps. cor.); removal of the 6-NH_2 group gives 2-(*o*-nitrophenyl)-5-methylbenzothiazole, m. 91.5–2°, thus establishing the structure of I. *2-(m-Nitrophenyl) deriv.*, orange-red, m. 233.5° (58.5% yield); the PhMe soln. has a yellowish red fluorescence. I and *p*-$O_2NC_6H_4CHO$ give as the main product *2-(p-nitrophenyl)-5-methyl-6-(p-nitrobenzalamino)benzothiazole* (III), dark red, m. 279°; the $C_6H_4Me_2$ soln. exhibits a greenish yellow fluorescence; a very small amt. of a bright orange compd., m. 312 5° (not cor.), is probably the 6-NH_2 deriv.; III is very stable to hydrolysis and is unchanged after refluxing several hrs. with 30% H_2SO_4 or concd. HCl; cold concd. HNO_3 gives a *mono-NO_2 deriv.*, reddish orange, m. 247.5°. *2-(o,p-Dinitrophenyl)-5-methyl-6-aminobenzothiazole*, red, m. 239.2° (30% yield); the C_6H_6 soln. has a greenish fluorescence. Reduction of II by Sn and concd. HCl gives 70% of the *2-(o-aminophenyl) deriv.* (IV), yellow or reddish violet, m. 251°; *2-(p-aminophenyl) deriv.*, orange-yellow or greenish yellow, m. 255.5°; the EtOH soln. has a purple fluorescence. IV, sulfonated and oxidized with NaOCl, gives a dye of Columbia Yellow type, black, amorphous, which is probably a mixt. of the di- and tetra-SO_3H acids. The *p*-NH_2 deriv. gives a mixt. of the di- and tetra-SO_3H acids, lustrous black solid. These dye unmordanted unbleached cotton a deep orange-tan, of approx. the same fastness as other dyes of this type. Diazotizing and coupling expts. with β-$C_{10}H_7OH$ indicate that the dye still retains free NH_2 groups; the azo dyes so produced were likewise direct dyes for cotton. *2-(o,p-Diaminophenyl)-5-methyl-6-aminobenzothiazole*, orange, m. 285.5° (not cor.); the EtOH soln. has a sky-blue fluorescence. A thiosulfuric acid of 2,4-$(H_2N)_2C_6H_3Me$ could not be prepd. by the above method. C. J. West

Triazole compounds. III. Alkylation of nitro-1,2,3-benzotriazoles. Oscar L. Brady and Cedric V. Reynolds. *J. Chem. Soc.* 1930, 2667–73; cf. *C. A.* 22, 1357.—6-Nitro-3-methyl-1,2,3-benzotriazole (I) and Me_2SO_4, warmed on the water bath for 1 hr., give *6-nitro-1,3-dimethyl-1,2,3-benzotriazolinium Me sulfate* (II), m. 110° (decompn.); boiling 2 *N* HCl gives the *chloride* (III), m. 136° (decompn.); heating II or better III regenerates I. 6-Nitro-1,2,3-benzotriazole, heated with excess of MeI for 2 hrs. at 100°, gives the iodide corresponding to III; similarly Me_2SO_4, heated 30 min. on the water bath, gives II; however, methylation with Me_2SO_4 in 2 *N* NaOH gives nearly quantitatively a mixt. of *6-nitro-1-methyl-1,2,3-benzotriazole* (IV), pale yellow, m. 187°, and I. III and Me_2SO_4, 30 min. at 100°, gives II. Reduction of III with $Na_2S_2O_3$ in EtOH gives the *6-NH_2 deriv.*, m. 201°. 7-Nitro-5-methyl-1,2,3-benzotriazole (V) and Me_2SO_4 in 2 *N* NaOH give some 1,5-di-Me deriv. (VI) and a larger amt. of the *3,5-di-Me deriv.* (VII), pale brown, m. 196°; reduction of the latter gives the *7-NH_2 deriv.*, m. 190°. V and Me_2SO_4, heated on the water bath for 10 min., gave a Me sulfate which did not crystallize; the chloride from this gave only VI when heated.

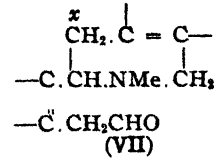


VII and Me_2SO_4 also gave an uncrystd. Me sulfate; the corresponding chloride, when heated, gives only VI. C. J. WEST

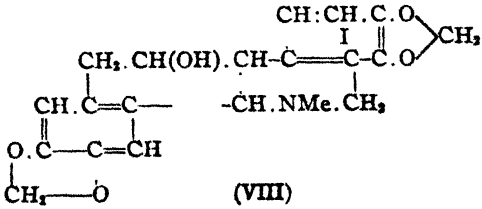
Rotenone. XI. Relation between isorotenone and rotenone. H. L. HALLER. *J. Am. Chem. Soc.* **53**, 733–7(1931); cf. *C. A.* **25**, 105.—Rotenonic acid, gently heated in concd. H_2SO_4 and AcOH until soln. results, isomerizes to *β-dihydrorotenone*, $C_{23}H_{24}O_6$ (I), m. 156°, $[\alpha]_D^{34}$ —26.5° ($CHCl_3$, *c* 5.86); it is insol. in alkali and is not a mixed anhydride, since it is recovered unchanged on refluxing in MeOH for 3 hrs.; it absorbs no H in AcOEt with Pt oxide; it reduces Fehling soln. Refluxing in EtOH-KOH for 3 hrs. gives *β-dihydrotubaic acid*, $C_{12}H_{14}O_4$, m. 175–6° (decompn.), gives a purple color with $FeCl_3$; this acid also results on alkali fusion of I. Oxidation of I with CrO_3 gives *β-dihydrorotenonone*, yellow, decomps. about 310°, while with $K_3Fe(CN)_6$ there results *dehydro-β-dihydrorotenone* (II), $C_{23}H_{22}O_6$, m. 269°, and with I in EtOH-AcOK, *β-dihydrorotenolone* (III), cream, m. 274°; boiling this with EtOH-H_2SO_4 gives II; the filtrate from III contains an *Ac deriv.* of III, m. 224°. Refluxing II with EtOH-KOH and Zn for 1.5 hrs. gives *dehydrodihydroxy-β-dihydrorotenonic acid*, m. 149°, which is oxidized with H_2O_2 in 5% NaOH to derric acid. A possible explanation is given of the fact that rotenone is readily reduced and isorotenone is not, and a relation between the two is indicated. C. J. WEST



Constitution of chelidonine. F. v. BRUCHHAUSEN AND H. W. BERSCH. *Ber.* **63B**, 2520–7(1930).—The structure assigned by Schwarz (*Diss. Marburg*, 1928) to chelidonine (I) on the basis of his observation that oxidation of the methine gives hydrastic acid and 2,4,5-$Me_2NCH_2(CH_2O_2)C_6H_2CO_2H$ (II) does not explain many of the reactions of I. The investigations of Kling (*Diss. Marburg*, 1927) gave the impression that the N is attached to two $PhCH_2$ groups. From this and from phylogenetic considerations



(III)



(IV)

(V)

(VII)

(VIII)

v. B. and B. have derived a structure for I which agrees most satisfactorily with all the known facts. Especial emphasis is laid on the close relationship between I and protopine (II) on the one hand and between homochelidonine and allocryptopine on the other. The 2 pairs have the same empirical formulas, $C_{20}H_{19}O_6N$ and $C_{21}H_{23}O_6N$, resp., and the same side chains (two CH_2O_2 groups in the 1 pair, one CH_2O_2 and two MeO groups in the other). The mother substance of II with its 10-membered ring may be considered to be tetrahydrocoptisine (III). Shifting of the HO group to C atom 3 would give a dihydronorprotopine (IV) which by addn. of HCHO on the N would yield the methanolamine and this by intramol. oxidation and reduction would form II. Shifting of the HO to C atom 1 would in the same way lead through an aldehyde (V) to bases (VI) of the type of narcotine and hydrastinine. Finally, shifting of the HO to C atom 5 would give a substituted $PhCH_2CHO$ (VII) which by intramol. aldol condensation with a reactive CH_2 group (*x* in formula VII) might yield I having

the structure **VIII**. **VIII**, however, on degradation should give 2,3,4-$Me_2NCH_2(CH_2O_2)$-$C_6H_2CO_2H$ (**IX**), not the 2,4,5-compd. (**II**), and, as a matter of fact, it was readily shown that the degradation product of **I** is really **IX**. The vinyl side chain in anhydrocryptopine is reduced by Pd-charcoal and H in MeOH, with formation of *allodihydroanhydrocryptopine* (**X**) (isomeric with the anhydrodihydrocryptopine B obtained by Perkin by reduction of the stilbene double bond with Na-Hg) which with Na-Hg gives *tetrahydroanhydrocryptopine* (**XI**), and **XI**, after *N*-methylation and renewed boiling with alkali, yields *des-N-tetrahydroanhydrocryptopine* (**XII**) which on oxidation gives *2-ethyl-4,5-dimethoxybenzoic acid* (**XIII**) and *2-dimethylaminomethyl-3,4-methylenedioxybenzoic acid* (**IX**), identical with Schwarz's supposed **II**. This was further confirmed by converting S.'s acid, after treatment with CH_2N_2 and exhaustive methylation, into 2,3,4-$Me(CH_2O_2)C_6H_2CO_2H$ by reductive degradation according to Emden. The structure **VIII** for **I** satisfactorily explains the Hofmann degradation of **I**.MeI and the conversion of **I** into chelerythrine. Homochelidonine may, in view of its relationship to allocryptopine, be considered as an **VIII** in which the CH_2O_2 group in nucleus I is replaced by two MeO groups, and Winterfeld's methoxychelidonine as **VIII** with a MeO group at *x*. **X**, yellow sirup quickly turning brown in the air; *methiodide*, m. 233° (cor., decompn.). **XI**, yellow-brown oil; *methiodide*, m. 222° (cor., decompn.). **XII**, faintly yellow, m. 99° (cor.). **XIII**, m. 146° (cor.). **IX** was isolated as the *chloroaurate*, m. 191°, in 0.08 g. yield from 1 g. **XII** with $KMnO_4$ in Me_2CO and in 0.25 g. yield with O_3 in 20% AcOH. C. A. R.

Tephrosin. I. Composition of tephrosin and its relation to deguelin. E. P. Clark. *J. Am. Chem. Soc.* **53**, 729-32 (1931).—The ext. from the leaves of *Cracca vogelii*, derris root and the roots of *Lonchocarpus nicou* (Cubé root), on fractional crystn. gives deguelin (**I**), m. 171° (cf. *C. A.* **25**, 938), and tephrosin (**II**), m. 198°. **I** and **II** form a mixt. which is difficult to sep. by fractional crystn. and which appears to be the material designated by Hanriot (*C. A.* **1**, 1013, 1435) as **II**. **II** may also be isolated by destroying **I** with CrO_3 in AcOH. **II**, $C_{23}H_{22}O_7$, n_α 1.590, n_β indeterminate, $n_\gamma > 1.74$, n_1 1.680. **II** is a dimethoxylactone, which gives with concd. H_2SO_4 in AcOH at 60° or with Ac_2O and AcOK, dehydrodeguelin. Oxidation with $KMnO_4$ gives *tephrosindicarboxylic acid*, $C_{23}H_{22}O_{11}$, m. 220° (decompn.), n_α 1.530, n_β indeterminate, n_γ 1.640. It is suggested that **II** is a hydroxydeguelin. C. J. West

Reaction of organic halides with piperidine. I. Alkyl bromides. Joseph Semb and S. M. McElvain. *J. Am. Chem. Soc.* **53**, 690-6 (1931).—The rate and course of the reaction between piperidine (**I**) and 18 alkyl bromides has been detd. Primary and sec. bromides, with the exception of cyclohexyl bromide, react with **I** to form tert. amines. Cyclohexyl bromide and the tert. bromides which were studied react, in the main, to lose HBr and form, presumably, an unsatd. compd. As a class the primary bromides react quite completely in 48 hrs.; iso-BuBr is an exception. There appears to be a distinct alternating effect of the Ph group on the reactivity of $PhCH_2Br$, $PhCH_2CH_2Br$ and $Ph(CH_2)_3Br$ when they are compared after a 4 hr. period of reaction. The sec. and tert. bromides are exceedingly unreactive at 90° when compared with the primary bromides; at 125-35° iso-PrBr and *sec*-BuBr definitely react to form a tert. amine but cyclohexyl bromide, when forced into a more complete reaction, shows practically the same tendency as the tert. bromides to lose HBr. This fact would seem to lend support to the suggestion that the sec. bromides which react with **I** to form a tert. amine probably rearrange to primary bromides before reacting and react as such. C. J. West

***ms*-Dichloroanthracene and its β-sulfonic acid as starting materials for manufacturing alizarin.** V. I. Minaev and B. P. Fedorov. *Zhur. Prikladnoi Khim.* **3**, 881-93 (1930); cf. *Zhur. Khim. Prom.* **6**, No. 7-8 (1929). Chlorination of anthracene in nitrobenzene: 178 g. dry anthracene suspended in 1200 g. $PhNO_2$ was directly chlorinated at 7-10° under const. stirring. When the increase in wt. was equal to that required by theory, the HCl formed was removed by air blowing, the mixt. settled 12 hrs. and the *ms*-dichloranthracene (**I**) (m. 202.7°, after recrystn. from C_6H_6, m. 209°) was filtered out, washed with EtOH and dried. The yield is 87%. Chlorination of anthracene in *o*-dichlorobenzene: 89 g. anthracene in 225 g. $C_6H_4Cl_2$ was chlorinated in a similar manner. Care must be taken in blowing air through the mixt. because of the volatility of the $C_6H_4Cl_2$ which may lead to excessive chlorination if the reaction is controlled by weighing the flask. The yield is 88%. Either method gives a pure product which does not require further purification. *ms*-Dichloroanthracene-β-sulfonic acid (**II**) was obtained as specified in Ger. pat. 292,590. Ten g. **I** was added to 36 g. benzene and 20.8% fuming H_2SO_4 mixed with 15 g. $PhNO_2$ was introduced by drops during 1 hr. 40 min., the temp. being kept at 9-11°. Stirring was continued for 6 hrs.

Next morning 40 cc. water was added and the $PhNO_2$ distd. with steam. The product was boiled in 1 l. water and filtered hot. The acid in the form of the Na salt was obtained from the filtrate by boiling with 20 g. NaCl. The yield is 81.5%. By using the exact amt. of free SO_3 in fuming acid required by the reaction the yield was raised to 93.3%. Only free SO_3 is active and the *mono-SO_3H acid* is practically the only product formed. Alizarin must be prepd. from anthraquinone-β-sulfonic acid (III) which is made from I by oxidation with HNO_3 or NO_2. The yield is 62.5%. The following new method was developed which gives 71.5% yield: I (+ SO_3 + HNO_3)⟶III⟶ alizarin. Add 62 g. technical I to 200 g. $PhNO_2$ and introduce at 8-12° during 2 hrs. 100 g. fuming H_2SO_4 (20% free SO_3) Stir for 2.5 hrs. longer and add 320 g. ice. Distil off the $PhNO_2$ with steam. Add carefully 32.3 cc. HNO_3 (d. 1.2), keeping the mixt. boiling under a reflux condenser Filter off the ppt. of unknown compn. Neutralize the filtrate by boiling with $CaCO_3$, filter and heat the filtrate with Na_2CO_3 to obtain the Na salt Mix 23.5 g. of this salt with 12 cc. water and add to 60 g. NaOH + 7.3 g. $NaNO_3$ + 70 cc. hot water. Heat in an autoclave for 28 hrs. at 179-183° and 9-11 atm. Dil. the product in 1200 cc. water and neutralize while boiling with 50% H_2SO_4 (about 120 cc). Boil for 1 hr. longer, cool and filter out the alizarin. V. K.

ω-Cyano-ω-arylideneacetanilides and the conversion of their *o*-nitro derivatives into quinoline derivatives. Mohammad Ishaq and Jñanendra Nath Rây *J. Chem. Soc.* **1930**, 2739-41.—It seemed that naphthinoline (Reissert, *Ber* **27**, 2244(1894)) might be obtained from I; however, reduction gave II. $PhNHCOCH_2CN$, m. 195°, with piperonal in pyridine contg. a trace of piperidine, heated at 60-70° for 1.25 hrs., gives *ω-cyano-ω-piperonylideneacetanilide*, m. 182°; *m-methoxybenzylidene deriv.*, m. 141°; *3,4-dimethoxybenzylidene deriv.*, m. 168°; *o-nitrobenzylidene deriv.* (I), yellow, m. 206°; *6-nitro-3,4-methylenedioxybenzylidene deriv.*, m. 227°; *6-nitro-3,4-dimethoxybenzylidene deriv.*, m. 169°. *α-Cyano-3,4-dimethoxybenzylideneaceto-p-toluide*, m. 198°; *m-methoxybenzylidene deriv.*, m. 144°, *o-nitrobenzylidene deriv.*, m. 182°; *6-nitro-3,4-methylenedioxybenzylidene deriv.*, m. 216°; *6-nitro-3,4-dimethoxybenzylidene deriv.*, m. 174° Reduction with Zn dust in boiling AcOH gives quinoline derivs. *2-Anilino-3-cyanoquinoline* (II), pale yellow, m. 208°; 6,7-methylenedioxy deriv., pale yellow, m. 287°; *6,7-dimethoxy deriv.*, m. 237°; *2-p-toluino-3-cyanoquinoline*, m. 221-2°, *6,7-dimethoxy deriv.*, m. 253°. C. J. West

Some indenoquinoline derivatives. Gurcharan Singh and Jñanendra Nath Rây. *J. Indian Chem. Soc.* **7**, 637-45(1930). *5,11-Indenoquinoline* (I) is best prepd by the following sequence of reactions *o*-$O_2NC_6H_4CHO$ (0.1 mol.), 1-hydrindone (0.1 mol) and Ac_2O (40 cc.) are refluxed for 2 hrs. giving *2'-nitrobenzylidine-1-hydrindone* (II), m. 167° Heating II with Zn and HOAc 1 hr. gives I, which was isolated as its HCl compd., pale yellow, m. 170.5° Derivs. of I are prepd similarly except that the reaction with Zn and HOAc must be performed in a H_2 atm The presence of air during the reduction causes a brilliant fluorescence which may be due to oxidation at the 5-carbon ring of I to give derivs of cyclopentamethine (cf Armit and Robinson, *C. A.* **16**, 2672); the isolation of such substances is being attempted The following substituted 1-hydrindones were prepd.: *6'-nitro-3',4'-methylenedioxybenzylidene*, yellow, m. 178°, *6'-nitro-3',4'-dimethoxybenzylidene*, yellow, m. 210°; *6'-nitrobenzylidene-4,5-methylenedioxy*, yellow, m. 212°, *6'-nitro-3',4'-methylenedioxybenzylidene-4,5-methylenedioxy*, deep yellow, m. 232°; *6'-nitro 3',4'-dimethoxybenzylidene-4,5-methylenedioxy*, yellow, m. 250°; *6'-nitrobenzylidene-4,5-dimethoxy*, lemon yellow, m. 188°; *6'-nitro-3',4'-methylenedioxybenzylidene-4,5-dimethoxy*, yellow, m. 232°; *6'-nitro-3',4'-dimethoxybenzylidene-4,5-dimethoxy*, yellow, m. 237°. These were converted into the corresponding derivs. of I which follow in the same order as the above: *methylenedioxy, HCl salt*, brick-red, m. 197° (decompn.); —; *methylenedioxy*, shrinks at 195° and m. 202°; *bis(methylenedioxy)*, m. 283°; *dimethoxymethylenedioxy, HCl salt*, yellow, shrinks at 255° and m. 257° (decompn.), *dimethoxy, HCl salt*, yellow, m. 232° (decompn.); *methylenedioxydimethoxy, HCl salt*, yellow, m. 270°; *tetramethoxy, HCl salt*, m. 235° (decompn.). Alk. condensation of desoxybenzoin and *o*-$O_2NC_6H_4CHO$ yields *3-o-nitrophenyl-1,2-diphenyl-Δ²-1-propenone*, yellow, m. 210°. A. F. Shepard

Action of guanidine and urea on some hydroxymethylene ketones. Erich Benayr. *Ber.* **63B**, 2601-8(1930).—In general, aliphatic and aliphatic aromatic hydroxymethylene ketones readily yield the corresponding aminomethylene compds with primary or secondary org. bases (*C. A.* **24**, 4507). In this connection the behavior of MeCOCH:CHOH (I) toward guanidine (II) was also studied. The Na deriv of I reacts with salts of II in alc. at room temp. with formation of 2-amino-4-methylpyrimidine (III), *i. e.*, not only is the HO group replaced by the guanidine residue but ring formation, with further elimination of water, also takes place. The reaction is quite general:

analogous products were obtained with the hydroxymethylene derivs. of MeCOEt, MeCOPr, methylheptenone (IV), MeCOPh, $MeCOC_6H_4Me$ and $MeCOC_6H_4OMe$. The III, now readily available, gives with Br in water a Br deriv. (V) in which the Br is held exceedingly firmly and must, therefore, be on the nucleus, probably in position 5. With acid chlorides, however, it readily forms *N*-derivs.; the $ClCH_2CO$ compd. (VI) with hot alc. NH_3 regenerates III in most part while a small part remains unchanged. The pyrimidine formation also takes place with the derivs. of cyclic ketones. Hydroxymethylenecyclohexanone yields *Bz-tetrahydro-2-aminoquinazoline* (VII) and the hydroxymethylene derivs. of cyclopentanone, menthone and carvone behave in the same way; as these require heat for the reaction and are, in general, more stable than the aliphatic compds., the desired products are most simply obtained by boiling the free hydroxymethylene compds. with I carbonate in alc. The reaction can be used quite generally to characterize those cyclic ketones which can yield hydroxymethylene derivs. All the bases so obtained do not turn litmus blue and their NH_2 group is held very firmly. The bases can be boiled a long time with dil. HCl without appreciable change and HNO_2 also generally has no action on them. Hydroxymethylenecamphor (VIII) treated as above gives only a trace of quinazoline (IX) which, however, is obtained quite smoothly in boiling AmOH instead of EtOH. Rupe found that with urea VIII splits off only 1 mol. water to form methylenecamphorurea, and B. has now found that ring formation likewise does not occur in the reaction of VIII with $CS(NH_2)_2$ or of hydroxymethylenecyclohexanone with urea. MeCOC(:CHOH)Me behaves in the same way. The hydroxymethylene ketones, therefore, resemble $AcCH_2CO_2Et$ in their behavior toward urea and II. With hydroxymethyleneacetoacetic ester, II gives iminomethyluracil, resulting from the action of II on $AcCH_2CO_2Et$, *i. e.*, the HOCH group is split off in the reaction. III is obtained in 51% yield. *5-Br deriv.* (V), m. 195°. *N-Chloroacetyl deriv.* (VI), turns green about 165°, then brown and completely decomps. 235°. *5-Me deriv.*, from MeCOC(:CHOH)Me, m. 216–7° (*N-chloroacetyl deriv.*, m. 145–8°). *4-Pr homolog* of III, m. 122–3°. *4-Ph analog*, m. 165°, easily sol. in dil. HCl. *4-p-Tolyl homolog*, m. 189–91°. *4-p-Methoxyphenyl compd.*, m. 185–7°. *4-(4'-Methyl-4'-pentene)-2-aminopyrimidine*, from the hydroxymethylene deriv. of IV, m. 155–9°. VII, m. 206–10°. *4,5-Trimethylene-2-aminopyrimidine*, from hydroxymethylenecyclopentanone, m. 206–8°. *5-Methyl-8-isopropyl-2-aminoquinazoline*, m. 139–41°; *Ac deriv.*, m. 125–7°. *2-Amino-5,6-dihydro-5-isopropenyl-8-methylquinazoline*, from hydroxymethylenecarvone, m. 165–7° (13 g. from 45 g. carvone). *2-Aminobornylenepyrimidine* (IX) (yield, 55%), m. 249–53°; *Ac deriv.*, m. 154–5°; *chloroacetyl deriv.*, m. 156–9°. *Methylenecamphorthiourea*, m. 213–4°. *Methylenecyclohexanoneurea*, light yellow, m. 229–30° (decompn.). *Methylenemethylethyl ketoneurea*, $MeCOC(:CHNHCONH_2)Me$, m. 156°. C. A. R.

Fungus dyestuffs. X. Xylindein, the dye from "green-rotted" wood. 2. Fritz Kogl and Hanni Erxleben. *Ann.* **484**, 65–84(1930); cf. *C. A.* **20**, 406; **25**, 291.—Xylindein (I), dissolved in concd. H_2SO_4 and AcOH and treated with H_2O_2 and 2 *N* HCl, gives 65–70% of a *compd.*, $C_{22}H_{26}O_{12}Cl_4$, yellow, decomps. 225–30°, sol. in alkali with a ruby-red color and giving a brown amorphous product on acidifying. Titration of I with NaOH indicates the formation of a tetra-Na salt, giving a malachite-green soln. in H_2O; I forms a di-Ag salt; MeI in $CHCl_3$ gives a *di-Me ester* of xylindeic acid (II), $C_{36}H_{44}O_{12}$, deep blue-violet needles, whose *tetra-Ac deriv.* forms yellow needles and whose *disemicarbazone* forms brown prisms. Reduction of the ester with Zn in Ac_2O-AcONa gives *di-Me hexaacetyltetrahydroleucoxylindeate* (III), light yellow needles. These facts indicate the presence of 2 enol-lactone groups in I. In the catalytic reduction of I 4 atoms of H are taken up, giving a yellow product, changing to green in the air; NaOH, followed by $AgNO_3$, gives a tetra-Ag salt, which reacts with MeI in $CHCl_3$ to give *di-Me tetrahydroxylindeate di-Me ether*, violet, which gives a *tetra-Ac deriv.*, $C_{36}H_{50}O_{17}$, yellow needles. The reducing acetylation of the ester by Zn in Ac_2O-AcONa gives a *compd.* $C_{40}H_{52}O_{17}$, yellow needles. Titration of the Na deriv. of I with $Na_2S_2O_4$ indicates that 2 atoms of H are absorbed per mol. of I. Tetraacetylxylindein gave only a trace of CH_4 with MeMgI, while *tetraacetylleucoxylindein*, $C_{36}H_{36}O_{16}$, yellow, shows the presence of 2 HO groups. Quant. oxidation of the Na deriv. of I indicates the consumption of 36 atoms of O and the formation of about 3 equivs. of volatile acids. Catalytic reduction of II gives a yellow leuco compd.; with CH_2N_2 this gives *di-Me hexahydroxylindeate tetra-Me ether*, yellow-brown, m. 247°. The sensitivity toward $KMnO_4$ and the resistance to hydrogenation may be easily explained by assuming that I contains a complicated quinone structure, whose double bonds are polyene-like through several nuclei. Taking up 2 H atoms causes the transformation into a stable benzoic system. Heating I at 175° with EtOH-KOH for 3 hrs. gives a little $PrCO_2H$ an

AcOH and about 18% of an *acid*, $C_{17}H_{14}O_{12}$, m. 199°, contg. 2 Ac groups (the product was acetylated to induce crystn.); CH_2N_2 gives the *compd.* $C_{20}H_{18}O_{12}$ or $C_{20}H_{20}O_{12}$, yellow, m. 165°, contg. 3 MeO groups; sapon. of the above acid gives the *compd.* $C_{18}H_8O_{10}$ or $C_{18}H_{10}O_{10}$, dark brown, m. 216°. Zn distn. of the acid m. 199° gave products from which no cryst. compd. could be isolated. Catalytic reduction of the acid gives a brown compd., m. 180–4°; alk. $KMnO_4$ oxidizes the acid, about 15 atoms of O being consumed. Zn distn. of III gives phenanthrene. C. J. WEST

The constitution of the artificial resins. M. KOEBNER. *Brit. Plastics* **2**, 197–8 (1930); *Plastics & Molded Products* **6**, 653–4; cf. *C. A.* **24**, 6039.—On addn. of 25 parts concd. HCl to a soln. of 168 parts *p*-cresol dialc. (I) in 1000 parts *p*-cresol a substance m. 215° (II) was obtained. On addn. of HCl to a mixt. of 2 parts *p*-cresol and 1 part 30% CH_2O the same substance together with another m. 126° (III) was obtained. An elementary analysis of these substances yielded almost the same % of C and H, but the mol. wt. was 228 and 348 for III and II, resp. As the simplest explanation for this the constitution 4,2,6-Me[5,2-Me(HO)$C_6H_3CH_2$]$_2C_6H_2OH$ was assumed for the "tri-body" (II) and [5,2-Me(HO)C_6H_3]$_2CH_2$ for the "di-body" (III). These formulas, which were confirmed by further investigations, gave reason to believe that the properties of the novolacks, resols and resites might be explained by the length of the chains. Contrary to PhOH and its homologs, *p*-cresol was found to give crystd. substances and the formation of the "tri-body" (II) at once showed the way to prep. chains of any length. The "tetra-, penta-, hexa- and hepta-body" were prepd. by condensing, resp., 2 mol. III with 1 mol. CH_2O, 2 mol. III with 1 mol. I, 2 mol. II with 1 mol. CH_2O and 2 mol. II with 1 mol. I. These formations and the properties of the substances support the hypothesis of Blumfeldt (*C. A.* **23**, 5179). Substances having chains with less than 7 links could be dissolved in aq. NaOH whereas such with 7 or more links were insol. A closer study indicated that the latter formed Na salts which were quite insol. in water. This apparent insoly. of the many-link chain substances in NaOH has misled many investigators. They concluded from the insoly. of the resites in NaOH that their phenolic character might have been lost by etherification or esterification. A splitting off of water as hitherto generally assumed in the transition of alkali-sol. resols to alkali-insol. resites and which by esterification or etherification should yield about 8% water cannot be considered as such substances thereby would be rendered completely unserviceable when they are to be converted from a fusible into an infusible state. The above-mentioned substances which seemed to be insol. in aq. NaOH could be readily dissolved in alc. NaOH. In this respect they differ from the resites, as, *e. g.*, prepd. from PhOH, which absorb NaOH without dissolving. This is not surprising considering the fact that PhOH renders possible far more complicated substitutions than *p*-cresol. *m*-Cresol behaves as PhOH, while *o*-cresol takes a middle place. The present explanation of the insoly. of the resites may be applied to almost all synthetic resins. D. THUESEN

The determination of amino acids formed by the hydrolysis of proteins. III. Application of the process of esterification and acetylation to the hydrolysis products of proteins. E. CHERBULIEZ, PL. PLATTNER AND S. ARIEL. *Helv. Chim. Acta* **13**, 1390–1402(1930); cf. *C. A.* **23**, 5161.—The esterification and acetylation of amino acids to yield stable products of the type RCH(NHAc)CO_2Et was applied to the mixt. obtained upon hydrolysis of serum albumin, casein and silk fibrin. It was found best to eliminate NH_3 and cystine (I) before esterification because the presence of acetylated esters of these compds. hinders the smooth distn. of the acetylated mixt. It is advisable to remove tyrosine (II) since its acetylation product is not found in the distillate. This finding is contrary to that expected from the behavior of the pure substance. The amino acids from serum albumin, after sepn. of NH_3 and I by addn. of phosphotungstic acid, yielded products that b_3 110–200°. From the fraction, b_3 105–15°, *active acetylleucine*, m. 181°, $[\alpha]_D^{29}$ —16.99°, was isolated. This product is purer than that obtained by Karrer (*C. A.* **15**, 1288) by direct acetylation of leucine. The m. p. is higher than that of the *racemate*, m. 161° (*Ber.* **34**, 449(1901)). Distn. of the acetylation products of a mixt. contg. I results in decompn.; a *gum* practically free from S is obtained. This gum is pptd. from its colloidal suspension in water by NH_4Cl soln. It does not give the biuret test and is not reduced by Fehling soln. The product from I alone yields the same gum. From the quantity formed, C., P. and A. confirm the idea that the S in serum albumin originates in I. Casein (500 g.) yielded 374 g. of acetylated esters. By means of a N balance, it was found that the yield of products from silk fibrin from which II and $NH_2CH_2CO_2H$ had been sepd. was very much higher than that obtained by other authors by direct acetylation. I. M. LEVINE

The action of chloral and trichloroacetic acid on cholesterol. XII. E. MONTIGNIE. *Bull. soc. chim.* [4], **37**, 1323–5(1930).—Isomerization of cholesterol (I) was brought about by heating in the presence of 4–5 times its wt. of Cl_3CCHO or Cl_3CCO_2H. The compds. $Cl_3CCO_2C_{27}H_{46}.H_2O$, m. 121°, and $Cl_3CCO_2C_{27}H_{45}$ (isomer), m. 140°, were isolated. More of the latter was formed at 100° than at 60°; 3% of meta-cholesterol, m. 140.5°, was isolated when Cl_3CCHO was used. An attempt to condense I with α- or β-$C_6H_7Ac_5O_6$ in the presence of HCl failed, proving the non-existence of a glucoside. I. M. LEVINE

Chlorophyll series. IV. The degradation of chlorophyll and allomerized chlorophyll to simple chlorins. J. B. CONANT, J. F. HYDE, W. W. MOYER AND E. M. DIETZ. *J. Am. Chem. Soc.* **53**, 359–73(1931); cf. *C. A.* **24**, 4047.—An improved method for the prepn. of pyrochlorin *e* (I) consists in boiling 1 g. of chlorin *e* with 100 g. Ph_2 5 min., pouring into 1 l. Et_2O and extg. with 1% HCl (15% yield); Me ester (II), m. 184°; the spectra of I in 8% HCl and of II in Et_2O and 10% HCl are given. The previous statement that I is unstable has not been verified; a soln. of II in glacial AcOH was boiled 24 hrs. without apparent change, decompn with EtOH-KOH and C_5H_5N at 220° for 5 hrs. gives phylloporphyrin. The Cu salt of II gives a deep blue-green color in Et_2O (spectrum given); the Fe salt gives a deep green ether soln. which, shaken with dil. NaOH, becomes brown, with an altered spectrum; shaking with acid restores the color and the original spectrum. The Zn salt in Et_2O is pure blue; 10–15% HCl exts. it with a pure green color. The reduction of I with H (catalytic or HI) gives a phyllochlorin. The prepn. of pyrochloroporphyrin and its reduction are described. Partial hydrolysis of crude pheophytin (*a* and *b*) with KOH in PrOH gives dimethylpheopurpurin 7, further hydrolyzed by the same agent to pheopurpurin 7 (III), a characteristic product of the phase test, allomerization and the phase test appear to be equiv. processes. III (a mono-Me ester) on pyrolysis loses CO_2 and CO, forming the mono-Me ester of a simple chlorin which appears to be a hydrogenated rhodophorphyrin; the mono-Me ester of chlorin *f* (IV) crystallizes in 8-sided plates, acid no. 11, giving a pure blue HCl soln. and a clear green Et_2O soln.; the soly. in Et_2O is about the same as that of chlorin *e*. CH_2N_2 gives the *di-Me ester*, needles, m. 182° (block), acid no. between 13–14, acid soln. blue. Porphyrin 8 is bluish green in acid soln. with a slight red fluorescence and crystallizes in prisms; porphyrin 6 crystallizes in plates and gives a purplish blue acid soln. The corresponding dibasic acid is formed by the action of hot EtOH-KOH on III, $(CO_2H)_2$ being split off; chlorin *f* gives a deep blue acid soln., the acid no. in 10 and the Et_2O soln. is green; the porphyrin was obtained in very small quantities, has an acid no. of 5–6 and gives a light blue acid soln. with a purplish red fluorescence. These facts show that III is an α-keto acid. Pyrolysis of chlorin *f* gives a mixt. of porphyrins, among which is pyrroporphyrin. The alkali decompn. of IV gives rhodoporphyrin, as does the decompn. of porphyrin 6 and 8. Sapon. of allomerized chlorophyll *a* yields III. I is a simple chlorin of the unallomerized series, it still contains the C atom which is eliminated as CO in the allomerized compd. It appears to be isomeric with phylloporphyrin. All these facts point to an oxidation-reduction process as being involved in the phase test and allomerization. C. J. W.

Porphyrin syntheses. XXXVI. Transformation of mesoporphyrin IX into a porphyrin monopropionic acid and several porphyrin syntheses. H. FISCHER AND A. ROTHHAAS. *Ann.* **484**, 85–112(1930); cf. *C. A.* **25**, 301.—Mesochlorin, obtained from mesoporphyrin IX (I), on reduction with Zn and AcOH and reoxidation, does not give I but a di-Me ester, m. 207° and giving a depression of 20° with the di-Me ester of I. It was therefore necessary to study the Zn-AcOH reduction of mesoporphyrins. The Zn-AcOH reduction of I and crystn. of the Na salts gives at least 3 compds. The Et_2O soln. of the porphyrins, extd. with very dil. NH_4OH (5 drops per l. H_2O), gives a product whose *di-Me ester*, $C_{36}H_{42}O_4N_4$, needles, m. 197° (cor.) (80–100 mg. from 4 g. I); it gives a depression of about 20° with the Me ester of isomesoporphyrin and the esters of mesoporphyrin I, VI, VIII, XI and XII. Further extn. of the Et_2O with 5–10% NH_4OH gives a product whose *Me ester* (150–200 mg.), $C_{36}H_{42}N_4O_2$ (?), does not have a const. m. p. (218–240°) and gives a considerable depression with the natural meso ester; the *Cu complex salt*, $C_{36}H_{40}N_4O_2Cu$, m. 175° (cor.). A 3rd ester (40 mg.), $C_{36}H_{44}O_6N_4$, m. 257° (cor.), which also gives a depression with the Me ester of I; *Cu complex*, m. 277° (cor.); *Fe complex*, bluish black needles. The crude porphyrin mixt., transformed into rhodins, gives a neutral fraction, bluish black needles, m. 259–60°, spectroscopically identical with mesorhodin (1.5–2% yield); the acid fraction, repeatedly fractionated from 1% HCl and esterified, gives needles, m. 205°, analyzing for $C_{37}H_{40}O_8N_4$, or a tripropionic acid. Zn-AcOH reduction of *mesoporphyrin XI* (II) gives 3 Me esters, m. 206°, 165.9° and 245.6°, resp. II was synthesized from the methenes

from opsopyrrolecarboxylic acid and the brominated methene from cryptopyrrolealdehyde and hemopyrrole; *Fe complex*, bluish black needles; *Cu complex*, red, does not m. 299°; *di-Me ester*, m. 174.5° (*Fe complex*, bluish black, m. 263°; *Cu complex*, m. 189°). 3-Ethyl-4-methyl-5-carboxyl-2-pyrrolealdehyde and 2,4-dimethyl-3-propylpyrrole with HBr and then with Br-AcOH give *4,3'-dimethyl-3-ethyl-4'-propyl-5-bromo-5'-bromomethylpyrromethene-HBr*, orange-red, decompg. 195°; with 3,5,3'-trimethyl-4-ethyl-4'-propionic acid-5'-bromopyrromethene-HBr this gives mesoporphyrin V and *1,3,5,8-tetramethyl-2,4-diethyl-6-propyl-7-propionic acid porphin*, whose *Me ester*, blue violet, m. 237° (cor.) (1.8% yield). 3,5-Dimethyl-4-propyl-2-pyrrolealdehyde and opsopyrrole in 48% HBr and EtOH give *3,5,3'-trimethyl-4-propyl-4'-ethylpyrromethene-HBr*, orange-red, m 211° (cor); with 4,5,3'-trimethyl-3-ethyl-4'-propionic acid-5'-bromopyrromethene-HBr there results mesoporphyrin II and 1.7% of *1,3,5,8-tetramethyl-2,4-diethyl-7-propyl-6-propionic acid-porphin*, whose *Me ester* m. 215° (cor.). Cryptopyrrolecarboxylic acid aldehyde and hemopyrrolecarboxylic acid in EtOH with concd. HCl or 48% HBr give *3,4',5,5'-tetramethyl-3',4-dipropionic acid-pyrromethene-HCl* or *HBr* (III), analyzed as the *di-Me esters*, yellow, m. 169–70°, and red, m. 180° (decompn.), resp; III with Br in AcOH gives *3,4'-dimethyl-3',4-dipropionic acid-5,5'-dibromomethylpyrromethene-HBr*, m. 191°. III and 3,3'-diethyl-4,4'-dimethyl-5,5'-dibromopyrromethene-HBr give *mesoporphyrin VI*, whose *di-Me ester* m. 199°, acid no. 2.4–2.5 (*Fe complex*, nearly black rods; *Cu complex*, red, m. 210°). The free mesoporphyrin VI has an acid no of 1.0, the HCl salt forms needles, the *Fe complex* is dark blue; the *Cu complex*, red, m. 314°. 3,3'-Dimethyl-4,4'-diethyl-5,5'-dibromopyrromethene-HBr and III give *mesoporphyrin VIII*, whose *di-Me ester*, red, m. 184–6° (cor.) and gives an *Fe complex*, bluish black, m 223°, and a *Cu complex*, red, m. 210° (cor.) The free porphyrin has an acid no of 1 and gives a bluish black *Fe complex*. The spectra of these compds. are given C. J. WEST

The bile acids. XXIX. MARTIN SCHENCK *Z. physiol. Chem.* **194**, 33–42(1931); cf. *C. A.* **24**, 5761.—Oxime acids of the bile acid series behave differently toward HNO_2 according to the position of the NOH. If this is on the 7-C atom of ring II there occurs merely a splitting off of the N-contg. group with formation of the corresponding keto acid. If, however, the NOH is on the 12-C atom of ring III there is formed a blue or greenish blue nitroso compd. or eventually a colorless nitro compd. Four addnl. examples of these 2 types have now been studied. Isodesoxybilianic acid oxime and cilianic acid oxime, representing the 1st type, yielded the keto acids isodesoxybilianic acid and cilianic acid, resp., in fulfilment of prediction. Isobilianic acid oxime lactam and isobilianic acid dioxime, representing the 2nd type, yielded with HNO_2 bluish green solns. from which dull-blue ppts. sepd on addn of water The lst of these NO derivs. could not be obtained pure, but when recrystd from AcOH the color disappeared and a ketolactamtricarboxylic acid was formed which differed from the parent substance only in the replacement of NOH by O. In contrast to the instability of the intermediate NO deriv. in this reaction, the NO deriv. from the dioxime acid was isolated but not in sufficient yield or purity for a satisfactory analysis An unsuccessful attempt was made to subject the oximinohydroxamic acid, obtained from 3,7,12-trioximinocholanic acid by reduction of its nitrohydroxamic acid, to the Beckmann-Wallach rearrangement with 90% H_2SO_4. The only substance isolated was the original material. A. W. DOX

Sterol group. X. Relationship of the fully saturated derivatives of ergosterol and sitosterol. FRANK S. SPRING. *J. Chem. Soc* **1930**, 2664–7; cf. *C. A.* **24**, 1388.—The crude product prepd. by hydrogenation of ergosterol in the usual manner, when fractionally crystd., gives 3 fractions of nearly pure α-ergostenol, the 4th fraction gave *γ-ergostenol* (I), m. 129 30°, $[\alpha]_D^{22}$ 5.1° ($CHCl_3$, *c* 3.2); fractionation of ergosterol and hydrogenation of the less and the more sol. fractions gave the same products; the isomer responsible for the appearance of I is concd. in the more sol. fractions of yeast ergosterols. I gives an *acetate*, m. 140°, which, with HCl in $CHCl_3$, gives the *acetate*, m. 103–4°, $[\alpha]_D^{22}$ 4.05° ($CHCl_3$, *c* 3.1) of *iso γ-ergostenol* (II), m. 129°, $[\alpha]_D^{22}$ 3.7° ($CHCl_3$, *c* 1.75). On catalytic reduction II absorbs 2 atoms of H, giving *γ-ergostanol*, m. 136°, $[\alpha]_D^{23}$ 29°, which appears to be identical with the sitostanol, m. 136°, $[\alpha]_D^{23}$ 26°, prepd. from cottonseed oil sitosterol. C. J. WEST

Reducing organic compounds. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Fr. 690,911, Feb. 7, 1930. Org. O compds. such as phenols, cresols or mixts. thereof with hydrocarbons are converted into compds. free from O by heating them under pressure with H and in the presence of a catalyst composed of a finely divided substance, such as charcoal or absorption C, intimately mixed with Mo or Mo compds. or substance contg. Mo. The conditions of the reaction are such that no splitting of the rings takes place.

Oxygenated organic compounds. I. G. FARBENIND. A.-G. (Heinrich Hopff, inventor). Ger. 512,718, Nov. 6, 1927. Aliphatic hydrocarbons are subjected to the action of CO in the presence of anhyd. $AlCl_3$ at temps below 100° under pressure. Several examples are given. In one, normal C_6H_{12}, CO and $AlCl_3$ are heated to 60° in a high-pressure bomb at 120–150 atm. The product includes a carboxylic acid $C_6H_{12}O_2$, b. 190–191°, and a ketone $C_6H_{12}O$, b 114–116°. Cf. *C. A.* **24,** 2755.

Temperature control in gas-phase partial oxidation of organic compounds. CHAS R. DOWNS (to Barrett Co.). U. S. 1,789,809, Jan. 20. In effecting catalytic reactions such as production of phthalic acid from naphthalene, a substantially constant and uniform temp. is maintained by the vaporization of a liquid such as Hg distributed within the zone of reaction in heat transfer relation with the catalyst but out of direct contact with it (as in tubes passing through the body catalyst). App. is described. The application on which this pat. was granted was filed June 11, 1919.

Introducing thiocyano groups into organic compounds. HANS P. KAUFMANN (to I. G. Farbenind. A.-G.). U. S. 1,790,097, Jan. 27. An inorg. thiocyanate such as NaSCN and a halogen such as Br or Cl (suitably with the use of HOAc as a solvent) are used together for introducing the SCN group into various org. compds. Examples are given of the treatment of ethylene (to form 1,2-dithiocyanoethane), styrene (to form 1-phenyl-1,2-dithiocyanoethane), anethole (to form 1-*p*-methoxyphenyl-1,2-dithiocyanopropane), aniline (to form *p*-thiocyanoaniline or 2,4-dithiocyanoaniline), diphenylamine (to form *p*-dithiocyanodiphenylamine), salicylic acid (to form 5-thiocyanosalicylic acid), 1-naphthol (to form 4-thiocyano-1-naphthol or 2,4-dithiocyano-1-naphthol) and 1- and 2-naphthylamine to form corresponding derivs. The products may be used as therapeutic agents, dye intermediates, etc. Cf. *C. A.* **24,** 4307.

1-Methyl-2-cyano-3-thiocyano-5-chlorobenzene, etc. I. G. FARBENIND. A.-G. (Richard Herz and Max Schubert, inventors). Ger. 511,211, Mar. 18, 1927. See U. S. 1,766,820 (*C. A.* **24,** 4308).

Hydrocarbons. URBAIN CHANDEYSSON. Fr. 691,886, Mar. 12, 1930. A hydrocarbon is obtained by incorporating CS_2 in a soln. of Na_2CO_3 in water and stirring for some days until a clear yellow liquid of Na_2S is formed which can be decanted from the

C which remains as a pure white liquid. H is passed in and combines with the C to form a hydrocarbon of d. corresponding to the amt. of H passed in.

Hydrocarbons. Soc. d'études scientifiques et d'entreprises industrielles. Fr. 692,395, June 12, 1929. Unsatd. hydrocarbons, particularly C_2H_2. and gaseous mixts. for the synthesis of oxygenated org. products and NH_3 are made by sepg coke-oven gas into its constituents by liquefaction, mixing the H or gas rich in H thus obtained with N obtained by sepn. of air into its constituents, using the O from this air for the regulated combustion of air or a part of the CH_4 or gas rich in CH_4 from the coke-oven gas sepg. the unsatd. hydrocarbons from the combustion and joining the residual gases of this sepn. composed of H, CO and some N, with the H from the coke-oven gas to form a mixt. suitable for the *synthesis of compds. such as MeOH and* NH_3.

Aromatic hydrocarbons. A. S. Ramage. Brit. 335,353, Sept. 3, 1929. Hydrocarbons such as benzene, toluene and zylene are produced by contact of a mixt. contg. unsatd. hydrocarbons (such as may be obtained by dehydrogenating light weathered products and casing-head gasoline vapors over ferric or cupric oxide) with CO and H (suitably water gas) with metallic iron at atm. pressure and a temp. of about 540–815° (the catalyst being maintained active by the presence of an excess of the hydrocarbon, and the reacting gases being, if necessary, freed from satd. hydrocarbons by passage over cupric or ferric oxide). An arrangement of app is described.

Polymerization of unsaturated hydrocarbons. I. G. Farbenind A.-G. Fr. 688,450, Jan. 18, 1930. In chem. reactions promoted by elec. wave discharges from dielec. surfaces or alternating elec. fields, such as the polymerization of unsatd. hydrocarbons, the reaction products are removed from the reaction chamber by heating the latter to a temp. at which all the products are gaseous or vapors.

Products from ethylene. N.-V. de Bataafsche Petroleum Maatschappij. Fr. 690,935, Feb. 26, 1930. Valuable products are prepd. from C_2H_4 and (or) its homologs by submitting the C_2H_4, etc , to a chem. treatment, in the presence or not of a catalyst, under pressure and at a high temp., in the presence or not of H, the reaction being carried out in a liquid medium which may be inert or not. As liquid medium there may be used hydrocarbon oils, oils from the destructive hydrogenation of carbonaceous materials, vegetable oils, phenols, water, an aq. soln. of a salt or the prepn. called "Edeleanu ext." Examples are given of the prepn. of AcOH and benzine hydrocarbons.

Purifying higher alcohols. I. G. Farbenind. A.-G. Fr. 690,958, Mar. 1, 1930. Resins are eliminated from products contg. higher alcs. such as montan wax, caranuba wax or beeswax by means of solvent for the resins, using solvents which form a homogeneous soln. such as aromatic and aliphatic hydrocarbons and solvents which give a dispersed soln. such as alcs., esters or ketones. The crude materials may first be sapond. to eliminate fatty acids. Thus, crude montan wax is melted and C_6H_6 is added, and the mixt. is allowed to cool with stirring. Cold alc. is then added while continuing to stir and on allowing to settle the soln. of resin is decanted.

Oxidization of alkylbenzenes. Joseph Binapfl and Willi Krey. U. S. 1,789,924, Jan. 20. Oxidation of alkylbenzenes with a side chain connected with 2 C atoms of the benzene nucleus is effected in liquid phase with a gas contg. O at a temp. above 50° (suitably 80° or higher in various examples given) in the presence of an oxidation catalyst such as finely divided oxides of Cu, Fe or Ni or mixts. of these with each other with or without carriers such as pumice, $CaCO_3$, silica gel or the like. Benzopolymethylene compds. such as hydrindene, tetrahydronaphthalene and substitution products such as those with a free α-position in the alicyclic ring are readily oxidized to alcs. and ketones. Several examples are given.

Substituted 1,3-diamino-2-propanols. Otto Eisleb (to Winthrop Chemical Co.). U. S. 1,790,042, Jan. 27. A secondary base such as diethylamine is caused to react with epichlorohydrin in mol. proportion, the intermediate product thus obtained is treated with caustic alkali, and the resulting compd. is treated with a N base such as NH_3 or a primary or secondary amine, for producing various 1,3-diamino-2-propanols, the asym. substituted derivs. of which may be used as intermediates in production of *therapeutic compds.* Details are given of the production of 1-amino-3-diethylamino-2-propanol and α-diethylaminoepihydrin, 1-ethylamino-3-diethylamino-2-propanol, 1-amino-3-piperidino-2-propanol and piperidinoepihydrin, and 1-amino-3-(phenylmethylamino)-2-propanol and α-phenylmethylaminoepihydrin.

Alkylcyclohexanols and -cyclohexanones. Schering-Kahlbaum A.-G. (Walter Schoeller, Hans Jordan and Reinhard Clerc, inventors). Ger. 512,881, Oct. 21, 1927. Addn. to 510,442. The hydrogenation process described in Ger. 510,442 (*C. A.* **25**, 974) is continued until the alkylphenols and other products formed have been completely hydrogenated. Examples are given.

Cyclic ketones. I. G. FARBENIND. A.-G. (Fritz Mayer, inventor). Ger. 513,204, Mar. 17, 1926. $C_{10}H_8$ or a halogen or alkyl substitution product is condensed with a β-halo fatty acid halide, the ketone so produced is caused to lose HCl, and the resulting unsatd. ketone is treated with condensing agents, whereupon ring closure occurs. The last two stages may be combined. Thus, α-methylnaphthalene is condensed with β-chloropropionyl chloride, giving 1-methyl-4-(β-chloropropionyl)naphthalene, which, when heated with H_2SO_4 and poured into water, yields *6-methyl-4,5-benzo-3-indanone*, m. 133°. Other examples are given also describing the prepn. of *1,6-dimethyl-4,5-benzo-3-indanone*, m. 70°; *6-chloro-4,5-benzo-3-indanone*, m. 143°; *4,5-benzo-3-indanone*, m. 103°; and *4,5-(2',6'-dimethylbenzo)-3-indanone*, m. 91°. Cf. *C. A.* **24**, 2469

Polycyclic ketones. I. G. FARBENIND. A.-G. (Otto Nicodemus and Walter Berndt, inventors). Ger. 512,717, Sept. 16, 1925. These are formed by passing the vapor of aromatic or heterocyclic ketones, which contain halogen in the *o*-position to the keto group and which are volatile under normal pressure or *in vacuo* (or their derivs. or substitution products), over highly porous heated bodies in the presence or absence of catalyzers. Thus, 1-*o*-chlorobenzoyl-2,6-dimethylnaphthalene gives 4-*Bz*-2-dimethylbenzanthrone, m. 152°; 1-*o*-chlorobenzoyl-2-methylnaphthalene gives 4-methylbenzanthrone, m. 127°, and *o*-chlorobenzoylbenzene gives fluorenone, m. 83°. Other examples are given. The yield in each case is 30–50%.

Substituted isocyclohexanols and corresponding ketones. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Hans Jordan, inventors). Ger. 512,719, June 30, 1926. Alkylisoalkylcyclohexanols and the corresponding ketones are prepd. by treating alkylisopropylenephenols with H under raised pressure and temp., in the presence of catalyzers, until 6 or 8 atoms are taken up. Thus, 3-methyl-6-isopropylenephenol is heated with H to above 150° under pressure, with a suitable catalyzer, until 8 H atoms are taken up. A 90% yield of menthol and a 5% yield of menthone results. The solidifying point of the mixt. is 12–7°. If the reaction is stopped after the taking up of 6 atoms of H, an almost 100% yield of menthone results. Another example is given.

Monocyclic lactones. SOC. ANON. M. NALF & CIE. Ger. 511,884, June 19, 1928. See *C. A.* **23**, 4483.

Separating amines. I. G. FARBENIND. A.-G. Fr. 691,614, Mar. 8, 1930. Primary and secondary aliphatic amines are sepd. by the reaction of the mixt. of aliphatic bases with an aromatic aldehyde, eliminating the secondary amine by distn., decomposing the aldehyde which remains by heating it with mineral acids and sepg. in the usual way the acid soln. of the primary amine from the aldehyde. Thus, $EtNH_2$ is sepd. from Et_2NH by BzH. Other examples are given.

Alkyl ethers of hydroxyalkylphenols. I. G. FARBENIND. A.-G. (Hans Hahl, inventor). Ger. 511,950, July 30, 1926. Basic alkyl ethers of hydroxyalkylphenols are prepd. by the action of basic alkyl halides on the phenols in the presence of alk. agents. Thus, the Na salt of 2,6-dimethyl-1-hydroxy-4-methylbenzene is heated with diethylaminoethyl chloride to give the corresponding ether as a thick oil which becomes a yellow liquid at 213–8° at 12 mm. Other examples are given.

Polysaccharide ether esters (for films, lacquers, etc.). I. G. FARBENIND. A.-G. Brit. 334,897, June 11, 1929. By causing a carboxylic acid having more than 6 C atoms to act on a polysaccharide ether, while heating, with or without use of a solvent, "indifferent liquid" or catalyst, products are obtained such as butylstarch linoleate, ethylcellulose esterified with fatty acids from coconut oil, benzylcellulose linoleate, ethylcellulose stearate and butylcellulose linoleate. H_3BO_3 may be used in small quantity as a catalyst and mention is made of the production of various products formed by the action of acids such as benzoic, salicylic, phenylacetic, undecylic, lauric, palmitic, stearic, oleic, linoleic, wood oil or abietic or other resin acids with ethers and mixed ethers of sucrose, starch, cellulose, etc.

Esters from nitriles. LUDWIG J. CHRISTMANN (to American Cyanamid Co.). U. S. 1,790,262, Jan. 27. In forming an ester such as ethyl lactate, a mixt. of a nitrile such as lactonitrile and an alc. such as EtOH in approx. theoretically combining proportions is treated with an inorg. acid which may be generated *in situ* (such as HCl generated by the action of H_2SO_4 on $CaCl_2$) to effect substantially complete reaction.

Carbohydrate esters. I. G. FARBENIND. A.-G. Fr. 691,031, Mar. 3, 1930. Carbohydrates or their conversion products are esterified with the amt. of fatty anhydride calcd. to form the triacyl compd. in combination with a fatty acid different from that of the anhydride used, in the presence or not of catalysts or diluents. Examples are given of the prepn. of the acetobutyrate and the butyropropionate of cellulose and the acetobutyrate of starch. Cf. *C. A.* **24**, 1650.

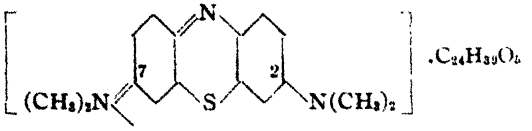
Esters of 4-hexen-3-ol. I. G. FARBENIND. A.-G. (Karl Böttcher, inventor)

Ger. 513,364, Mar. 27, 1925. Addn. to 512,232 (*C. A.* **25**, 1037). Esters of 4-hexen-3-ol with halogen hydracids are prepd. by interaction of the alc. and the concd. acid at atm. temp. Examples are given. *4-Bromo-2-hexene* b_9 40–2°.

Silicic acid esters. I. G. FARBENIND. A.-G. (Martin Müller-Cunradi and Grete Lechner, inventors). Ger. 512,716, Jan 19, 1927. The esters are prepd. by the action of alcs. on $SiCl_4$ in the presence of indifferent diluents. Thus, $SiCl_4$ and EtOH are allowed to react under exclusion of moisture, diluted with a large vol. of C_6H_6. A 70% yield of $(Et)_2SiO_3$ is distd. off between 162–5°. Other examples are given.

Basic products from imido esters of the higher fatty acids. I. G. FARBENIND. A.-G. (Max Bockmühl and Robert Knoll, inventors). Ger. 512,721, Mar. 20, 1928. Basic products are obtained by condensing the imido esters of higher fatty acids with diamino compds. in which the amino groups are bound by an aliphatic or hydroaromatic linkage. Thus, a suspension of the imido-ethyl ester of palmitic acid in abs. alc. and 1-diethylamino-2-hydroxypropylamine are heated together for 6-8 hrs. On distg. off the alc. the new substance is obtained as a thick oil. The monohydrochloride m 38–9° and the dihydrochloride m. 156°. Other examples are given. Cf. *C. A.* **24**, 2244.

Diesters of carboxylic acids. CANADIAN ELECTRO PRODUCTS CO., LTD., F. W. SKIRROW and G. O. MORRISON. Brit. 335,223, March 18, 1929. Esters such as ethylidene diacetate are produced as described in Brit. 308,169 (*C. A.* **24**, 129). Any vinyl ester formed is returned to the reaction chamber and converted into the diester. Examples and details are given.



Polysulfides of aromatic carboxylic acids. ROBERT EDER. Ger. 512,567, May 10, 1928. See U. S. 1,769,423 (*C. A.* **24**, 4522).

Arylides of hydroxycarboxylic acids. I. G FARBENIND. A.-G. Fr. 690,662, Feb 25, 1930. Arylides of hydroxycarboxylic acids are prepd. by heating hydroxyphenylarylaminocarboxylic acids (obtained by heating the alkali salts of *m*-hydroxyphenylarylamines with CO_2 under pressure) or their *N*-acyl compds. with arylamines in dispersing agents or solvents, in the presence of condensing agents, and sepg., if necessary, the acyl group. Several examples and a long list of components with the m. ps. of the products are given Cf. *C. A.* **24**, 5308.

Cyanoformic arylides. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORMALS ROESSLER. Ger. 511,886, Feb. 21, 1928. See Fr. 669,678 (*C. A.* **24**, 1867).

Disubstituted ureas and their reaction products. HEINRICH VON DIESBACH. Ger. 511,210, Dec 11, 1928. Hydroxy or amino compds. of the C_6H_6 or $C_{10}H_8$ series are condensed with dimethylolurea (I). According to the proportions taken, the condensation may affect one or both of the methylol groups. On sapong., benzylamine derivs. are generally obtained from products of the C_6H_6 series, and *sym*-diarylethanes from products of the $C_{10}H_8$ series. Condensation and sapon. may be effected in one working operation. According to some of the examples, (1) PhOH and I yield *α-hydroxymethyl-β-(2-hydroxybenzyl)urea*, m 155°; (2) *p*-cresol and I yield *2,2'-dihydroxy 5,5'-dimethyldibenzylurea*, m. 70°; (3) *p*-nitrophenol and I yield *α-hydroxymethyl-β-(2-hydroxy-5-nitrobenzyl)urea*, decompg. 181°; (4) *o*-nitrophenol and I yield *sym-4,4'-dihydroxy-5,5'-dinitrodibenzylurea*, m. 215–6°, which yields 5-nitro-4-hydroxybenzylamine when heated with concd. HCl; (5) resorcinol and I yield *2,2',4,4'-tetrahydroxydibenzylurea*, decompg 134–40°; (6) 2-naphthol and I yield *di(1-methyl-2-naphthol)urea* (II), m. 205°; (7) 1-naphthol-2-carboxylic acid and I yield *di(4-methyl 1-hydroxy-2 carboxynaphthalene)urea*, m. 202°; (8) II is sapond. with alc. HCl, yielding *α,β-di(2-hydroxynaphthyl)ethane*.

Bile acid salts of thiazine. CHEMISCHE FABRIK VORM. SANDOZ Ger. 511,810, Dec 30, 1927. These salts are prepd. by the action of bile acids on diaminophenothiazine or its *N*-alkyl- or nuclear alkyl- or alkoxy-substitution products. Thus, 2,7-tetramethyldiaminophenothiazonium chloride in water is treated with Na cholate to give salt

Other examples describe the salts formed by the other thiazonium chloride compds. with Na desoxycholate, Na taurocholate and Na glycocholate. *The salts are strong bactericides.* Cf. *C. A.* **24**, 629.

Alkali salts of aromatic sulfohaloamides. CHEM. FAB. VON HEYDEN A. G. (Curt

Philipp, inventor). Ger. 514,094, July 7, 1927. These are prepd. by the reaction of aromatic sulfodihaloamides in aq. soln. with 2 or more mols. of alkali in the presence of aromatic sulfonamides. Thus, toluenesulfodichloroamide (1 mol.) reacts in aq. soln. with NaOH (2 mol.) in the presence of toluenesulfonamide (1 mol.), and the soln. then evapd. to yield the Na salt of toluenesulfochloroamide.

Hydroxy sulfonylchlorides. ERICH GEBAUER-FÜLNEGG and EUGEN RIESZ. Austrian 119,960, June 15, 1930. Hydroxy sulfochlorides prepd. by the reaction of phenols with HSO_3Cl are isolated by pouring the reaction mixt. into concd. HCl, the sulfochloride then sepg. out. Examples are given describing the prepn. of *phenol-2,4-disulfonylchloride*, m. 89°, *1,3,5-trihydroxybenzene-2,4-disulfonylchloride*, m. 184°, and *3-hydroxytoluene-2,4,6-trisulfonylchloride*, m. 151°.

Sulfurized compounds of phenols. ALFRED THAUSS and ALFRED GÜNTHER (to General Aniline Works). U. S. reissue 17,940, Jan. 27. Reissue of original pat. No. 1,450,463 (*C. A.* **17**, 1893).

Derivatives of α-hydroxyallyl alcohol. SCHERING-KAHLBAUM A.-G. (Hermann Fischer, inventor). Ger. 514,093, Feb. 24, 1929. Acetone glycerol-α-chlorohydrin is distd. over alk. reagents, whereby HCl is split off and the acetone deriv. of α-hydroxyallyl alc. is obtained. The same or corresponding derivs. may be prepd. similarly from other esters of acetone glycerol or from esters of condensation products of glycerol with other carbonyl compds. Cf. *C. A.* **15**, 686.

Derivatives of di-*o*-benzoylene-1,10,6,5-pyrene (pyranthrone). I. G. FARBENIND. A.-G. Fr. 677,549, June 28, 1929. Derivs. of di-*o*-benzoylene-1,10,6,5-pyrene are prepd. by replacing the NO_2 groups in the NO_2 derivs. by other groups. The NO_2 compds. may be reduced to NH_2 compds. and one or both H atoms may then be replaced by univalent radicals. Examples are given of the prepn of monochloro, tetrachloro, benzoylamino and tetrahydroxy derivs. and condensation products of the amino derivs. with 1-chloroanthraquinone and monobromodibenzanthrone. Cf. *C. A.* **24**, 2307.

Derivatives of 4-aminodiphenylamine. I. G. FARBENIND. A.-G. (Johann Büsdorf and Fritz Löflund, inventors). Ger. 512,722, Feb. 16, 1929 Addn. to 499,824 (*C. A.* **24**, 4521). The method of 499,824 for producing the above derivs. is modified by condensing equimol. amts. of nitrobenzene and *o*-substituted nitrosobenzene with a free *p*-position, and treating the product with reducing agents. Thus, nitrosobenzene and *o*-nitrosoanisole in glacial AcOH are condensed in the presence of concd. H_2SO_4, and the product, m. 153°, salted out. This product is reduced by Na_2S to give 4-amino-3-methoxydiphenylamine, m. 87°. Another example is given

Aminodiphenylamine derivatives. I. G. FARBENIND. A.-G. (Johann Büsdorf and Fritz Löflund, inventors). Ger. 511,526, Feb. 16, 1929. Addn to 499,824 (*C. A.* **24**, 4521). The method of 499,824 for producing derivs. of 4-aminodiphenylamine is modified by condensing equimol. mixts. of *p*-substituted nitrosobenzene and non-substituted nitrosobenzene and treating the product with reagents. Thus, *p*-chloronitrosobenzene and nitrosobenzene are condensed and treated with glacial AcOH and H_2SO_4, giving a product m. 143°. This is treated with NaOH or anhyd. Na_2S to give 4-amino-4'-chlorodiphenylamine, m. 70–71°. Another example is given.

Anthraquinone derivatives. IMPERIAL CHEMICAL INDUSTRIES, LTD. Ger. 511,320, Sept. 27, 1929. This corresponds to Brit. 322,576 (*C. A.* **24**, 2896), but includes also the treatment of 1-aminoanthraquinone-2-sulfonic acids unsubstituted in the 4-position. Addnl. examples are given also.

Benzanthrone derivatives. I. G. FARBENIND. A.-G. (Arthur Lüttringhaus and Paul Nawiasky, inventors). Ger. 511,946, Jan. 17, 1926. Benzanthrone having an O-contg. residue in the *Bz*-1-position is treated with acid halides. Thus, *Bz*-1-phenoxybenzanthrone is treated with *o*-chlorobenzoyl chloride. Cf. *C. A.* **24**, 2148.

Benzanthrone derivative. I. G. FARBENIND. A.-G. (Gustav Reddelien and Hans Lange, inventors). Ger. 511,951, Aug. 1, 1928. Addn. to 442,774. ω-Aminomethylbenzanthrone is prepd. by the action of benzanthrone on ω-halomethylphthalimide. $ZnCl_2$ may be present as a catalyzer. Cf. *C. A.* **25**, 712.

Carbazole derivatives. I. G. FARBENIND. A.-G. (Friedrich Muth and Albert Schmelzer, inventors). Ger. 511,021, Jan. 3, 1928. Addn. to 507,797 (*C. A.* **25**, 716). Substituted carbazolesulfonic acids other than the 1-amino compd. of 507,797 are used. Examples mention the prepn. of 1,8-dihydroxycarbazole (m. 211–2°) from K 1,8-dihydroxycarbazole-3,6-disulfonate, 1-amino-8-hydroxycarbazole (m. 216–7°) from Na 1-amino-8-hydroxycarbazole-3,6-disulfonate, 1-nitrocarbazole (m. 184°) from the di-Na salt of 1-nitrocarbazole-3,6,8-trisulfonic acid and 1-chlorocarbazole (m. 125°) from Na 1-chlorocarbazole-3,6,8-trisulfonate. Cf. *C. A.* **25**, 965, 966.

Guanidine derivatives. SCHERING-KAHLBAUM A.-G. (Herbert Schotte, inventor). Ger. 512,880, Feb. 25, 1927. Addn. to 506,282. The method of Ger. 506,282 (*C. A.* **25**, 304) is improved by working with an amt. of solvent insufficient to dissolve completely the amine salt. Examples are given. Cf. *C. A.* **25**, 712.

Guanidine derivatives. SCHERING-KAHLBAUM A.-G. (Herbert Schotte, inventor). Ger. 514,248, Sept. 13, 1927. Substituted guanidines are prepd. by treating a disubstituted cyanamide with an amine salt in the presence of free amine. Thus, diethylcyanamide and $PhNH_2.HCl$, heated for 10 hrs. at 100° in the presence of $PhNH_2$, yield *N,N*-diethyl-*N'*-phenylguanidine. Other examples are given also. In some cases the reaction mixt. need not be heated.

Naphthalene derivative. I. G. FARBENIND. A.-G. (Richard Herz and Fritz Schulte, inventors). Ger. 511,022, Dec. 21, 1928. A β-aminonaphthalenesulfocarboxylic acid is prepd. by nitrating the anhydride of 1,8-naphthalenesulfocarboxylic acid and reducing the nitro compd. An example is given. Cf. *C. A.* **25**, 966.

Pyridine derivatives. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM. ROESSLER (Gerd Kochendoerfer, inventor). Ger. 513,293, Jan. 25, 1925. Amino- or hydroxy-pyridines or their nuclear substitution products are iodized by treatment with I, or reagents yielding I, in a feebly alk. or neutral medium and in the presence of an acid-binding agent, *e. g.*, Na_2CO_3 or borax. Examples are given describing the prepn. of 2-amino-5-iodopyridine, *2-hydroxy-3-iodo-5-nitropyridine*, m. 203°, and 2-hydroxy-3,5-diiodopyridine. Cf. *C. A.* **24**, 2472.

Quinoline derivatives. I. G. FARBENIND. A.-G. (Fritz Schönhöfer, inventor). Ger. 511,466, Dec. 18, 1927. Aminoalkyl derivs. of quinoline are prepd. by condensing *o*-aminobenzaldehyde or *o*-aminoacetophenone with aliphatic amino ketones. The reaction may be effected at ordinary or raised temp., and a catalyst may be present, *e. g.*, NaOH or piperidine. Examples are given. Cf. *C. A.* **25**, 966.

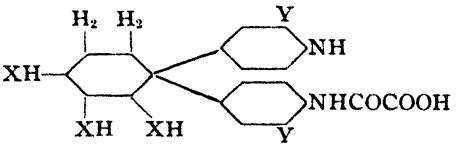
Quinoline derivative. I. G. FARBENIND. A.-G. (Paul Baumgarten, inventor). Ger. 512,720, Aug. 22, 1928. 2,4-Diketo-1,2,3,4-tetrahydroquinoline is prepd. by heating the amide of malonic acid or one of its alkyl or aryl derivs., with primary or secondary aromatic amines. Thus, the diamide of ethylmalonic acid is heated to 220° with N-methylaniline in a reflux condenser till NH_3 is evolved. The excess of methylaniline is removed by HCl and a 90% yield of 1-methyl-3-ethyl-2,4-diketo-1,2,3,4-tetrahydroquinoline, m. 184–185° (uncor.), obtained by crystn. Other examples are given.

Condensation products. I. G. FARBENIND. A.-G. (Myrtil Kahn, Wilhelm Schepss and Ludwig Zeh, inventors). Ger. 513,207, Oct. 10, 1926. Addn. to 484,837 (*C. A.* **24**, 1120). The methods of 484,837 and 494,803 (*C. A.* **24**, 3516). for forming aromatic condensation products from primary and secondary amines and hydroxybenzyl halides is modified by replacing the latter substances by hydroxyarylhalomethane compds. which contain more than one benzene nucleus. Thus, monomethylaniline is condensed with 1-ω-chloromethyl-2-hydroxynaphthalene-3-carboxylic acid. Other examples are given.

Condensation products of the perimidone series. I. G. FARBENIND. A.-G. (Walter Mieg and Rudolf M. Heidenreich, inventors). Ger. 511,948, Dec. 17, 1925. See U. S. 1,749,955 (*C. A.* **24**, 2149).

Separating mixtures of formic and acetic acids. I. G. FARBENIND. A.-G. (Irnfried Petersen and Curt Engelbrecht, inventors). Ger. 513,024, Feb. 8, 1928. The acids are sepd. by distn., after addn. to the mixt. of a liquid which is miscible with AcOH but immiscible or only slightly miscible with HCOOH, and which forms an azeotropic mixt. with HCOOH. Suitable liquids are C_2HCl_3, CCl_4, C_6H_6 and benzine. Examples are given.

Glycidic acids. A. A. KAUFMANN. Brit. 335,391, Oct. 8, 1929. See Fr. 682,471 (*C. A.* **24**, 4306).



1-Bromo-2-aminoanthraquinone-3-carboxylic acid. I. G. FARBENIND. A.-G (Max. A. Kunz and Erich Berthold, inventors). Ger. 511,470, Aug. 19, 1927. 2-Nitro-3-methylanthraquinone is treated with Br at ordinary or raised pressure, preferably in the presence of a solvent or diluent. The product m. 323–5° (decompn.). Examples are given.

Anthraquinonesulfonic acids. JOHN THOMAS (to Scottish Dyes, Ltd.). U. S. 1,790,448, Jan. 27. β-Monosulfonic acids of anthraquinone are formed by mixing together 2-benzoylbenzoic acid, an excess of oleum and V pentoxide and heating to about 150°.

Sulfonic acids of nitrohalodiaryl ketones or sulfones. I. G. FARBENIND. A.-G. (Winfrid Hentrich, Rudolf Knoche, Ernst Tietze and Josef Hilger, inventors). Ger. 514,234, July 5, 1928. These sulfonic acids are readily prepd. by sulfonating nitro-

halodiaryl ketones or sulfones contg. halogen in the nitrated nucleus. The SO_3H group is believed to enter the unnitrated nucleus in the *m*-position to the CO or SO_2 group. The sulfonic acids may be further treated to replace the halogen atom by NH_2 or OH, or to reduce the NO_2 group. Useful *intermediates for dyes* are so obtained. Examples are given. Cf. *C. A.* **24**, 3250.

Mono-oxamic acids of 4,4'-diaminodiarylcyclohexane compounds. GEORG KALISCHER and RICHARD FLEISCHHAUER (to General Aniline Works). U. S. 1,789,903, Jan. 20. Mono-oxamic acids of 4,4'-diaminodiarylcyclohexane compds. which correspond to the general formula:

(wherein one X means H or Me, the other X's H and the Y's stand for H, halogen, Me or alkoxy groups) are obtained by treating 4,4'-diaminodiarylcyclohexane compds. with oxalic acid. The starting bases are heated with oxalic acid until they have mostly disappeared, advantageously in the presence of a solvent, as water or an inert org. solvent, care being taken that the quantity of the oxalic acid applied does not substantially surpass that necessary for dissolving the bases. The mono-oxamic acids are difficultly sol. in water and in org. solvents. Their Na and K salts are difficultly sol. in cold water, more sol. in hot water. The new products contg. a free amino group capable of being diazotized, are *intermediates for the production of dyes*. Several examples are given.

Acetic anhydride. IMPERIAL CHEMICAL INDUSTRIES, LTD., H. HEPWORTH and F. D. LEICESTER Brit. 334,986, July 4, 1929. Ac_2O is sepd. from vapors contg. HOAc and steam by use of active carbon. Various details of operation are described

Acetic anhydride. A. L. SHAPIRO. Russ. 58,598, Nov. 25, 1929. Addn. to Russ. 17,216. A mixt. of $AcNH_2$ and glacial AcOH is acted upon with HCl instead of H_2SO_4.

Crystalline phthalic anhydride. LLOYD C. DANIELS and CHRISTIAN J. SCHWINDT (to Selden Research Engineering Corp.). U. S. 1,789,967, Jan. 27. Cryst. phthalic anhydride substantially free from phthalic anhydride dust is prepd. by disintegrating needle crystals in app. such as a dough mixer.

Aromatic mercaptans and thioglycolic acids. I. G FARBENIND A.-G. (Richard Herz and Max Schubert, inventors). Ger. 513,208, Mar. 25, 1927. *o*-Cyanoaryl mercaptans are prepd. by treating *o*-cyanoaryl thiocyano compds. in aq. or alc. soln. with alk. sapong. agents in the presence of reducing agents ($Na_2S_2O_4$ or Zn), or with alkali sulfides or polysulfides Thus, 1-methyl-2-cyano 3-thiocyano-5-chlorobenzene, heated with Na_2S_2, yields 1-methyl-2-cyano-5-chlorobenzene-3-mercaptan. Other examples are given also. *o*-Cyanoaryl thioglycolic acids are prepd. by condensing the mercaptans with $ClCH_2COOH$.

1,1,2-Trichloroethane. CONSORTIUM FÜR ELEKTROCHEMISCHE IND G. M. B. H. Fr. 690,767, Feb. 27, 1930. 1,1,2-Trichloroethane is prepd. by passing vinyl chloride and Cl in the presence of 1,1,2-trichloroethane or other solvents over Cl carriers, particularly $SbCl_5$.

1,1,2-Trichloroethane. I. G. FARBENIND. A.-G. Fr. 690,655, Feb. 25, 1930 Crude chloroethylene obtained by incomplete substitution from C_2H_2 and HCl, with intervention of a catalyst, is treated directly with Cl. Cf. *C. A.* **23**, 2724.

1-(4'-Aminophenyl)-1-hydroxy-2-methylaminopropane. FIRMA E. MERCK. (Otto Dalmer and Max Oberlin, inventors). Ger. 511,469, Aug. 8, 1929. 1-Phenyl-1-hydroxy 2-methylaminopropane or its salts is nitrated at a temp. not exceeding 20°, and the nitro compd. is reduced. Examples are given. The product m. 114–6° and is less poisonous than the initial material. Cf. *C. A.* **24**, 4793.

Acetylene. I. G. FARBENIND. A.-G. (Bernhard C. Stuer and Walter Grob, inventors). Ger. 511,634, Mar. 6, 1915. C_2H_2 is converted into AcH and other condensation or oxidation products by leading it, mixed with at least 3 times its own vol. of steam, over catalyzers at high temps. Thus, the mixt. is led through a tube contg. powd. bog Fe ore at 400–420° to give AcH, AcOH, acetone and phenolic condensation products.

Acetylene. INTERNATIONAL INDUSTRIAL & CHEMICAL CO. Fr. 692,451, June 19,

1929. CH_4 is transformed into C_2H_2 by a heat treatment of 750–2,000°, C_2H_4 being a by-product of the reaction. The pressure and speed of the gas is varied according to the compn. of gas product desired. Fr. 692,452 describes the conversion of CH_4 into C_2H_2 and the hydrogenation of the latter into C_2H_4 which is condensed with water gas to higher hydrocarbons. The product of the first conversion contg. C_2H_2 is cooled rapidly to stabilize it.

2,6-Xylidine. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 692,041, Mar. 17, 1930. See Brit. 328,418 (*C. A.* **24**, 5309).

2,4-Xylidine. SILESIA, VEREIN CHEMISCHER FABRIKEN. Fr. 691,911, Mar. 14, 1930. 2,4-Xylidine is extd. from tech. mixts. of xylidine by dissolving the mixt. in an anhyd. solvent which does not mix with water, such as benzene, benzine and ether, and pptg. the hydrochloride of 2,4-xylidine by introducing dry HCl gas.

Methanol. BRITISH CELANESE, LTD., W. BADER and E. B. THOMAS. Brit. 334,924, April 12, 1929. ZnS (alone or mixed with Cr oxide or other promoters) is used as catalyst in synthesizing MeOH from C oxides and H (suitably at 360–400° and under 100 atm. pressure). Details for prepg. the catalyst are given

Aluminum alcoholates. A. WACKER GES. FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit 334,820, June 13, 1929. Al alcoholates contg. some $AlCl_3$ (suitable for use as catalysts for conversion of AcH into EtOAc) are prepd. by treating Al (suitably in the form of chips) and an alc. such as abs. EtOH with Cl or a Cl compd. such as HCl which is capable of parting with Cl to Al Various details of procedure are described.

Urea. I G. FARBENIND. A.-G. (Wilhelm Meiser, inventor). Ger. 511,465, Mar. 20, 1929; Fr 691,069, Mar. 4, 1930. This relates to the removal of combined NH_3 and CO_2 from urea prepd. by the reaction of NH_3 and CO_2 under pressure. CO_2 and some NH_3 are first removed by distn. under high pressure in the presence of an excess of NH_3, and the residual NH_3 is then removed by distn. at a relatively low temp. and pressure. An example is given

Formamide. I. G FARBENIND A.-G. (Reinhold Fick, inventor). Ger. 511,885, June 8, 1924. Addn to 485,989 (*C. A.* **24**, 1185). For the production of HCN by the catalytic decompn of $HCONH_2$ and $HCOONH_4$ by the methods of 485,989 and 510,407 (*C. A.* **25**, 1040), the $HCONH_2$ is obtained by passing $HCOONH_4$ or HCOOH or both mixed with NH_3, over catalyzers at high temps. Thus, water-free $HCOONH_4$ and NH_3 are led over glowing bauxite at 140–170°. The gases are then cooled to 60° and the $HCONH_2$ is sepd. by addn. of water.

Benzene. GES. FÜR LINDE'S EISMACHINEN A.-G. Ger. 511,567, Aug. 5, 1926. The sepn. of C_6H_6 and hydrocarbons from distn. or similar gases by expansion, cooling and condensing, is described. The layout is indicated. Cf. *C. A.* **25**, 583

5-Chloro-2-amino-1-methoxybenzene. I. G. FARBENIND. A.-G. (Wilhelm Fitzky, inventor). Ger. 511,468, Jan. 18, 1928. *sym*-Di(*o*-methoxyphenyl)urea is chlorinated and the dichloro deriv. so obtained is treated with alk. reagents. An example is given

Thiophenols. I. G FARBENIND. A.-G. (Alfred Thauss and Fritz Ballauf, inventors). Ger. 510,444, Jan 1, 1929. Addn. to 496,903 (*C. A.* **24**, 3518). The method of 496,903 for producing colorless thiophenols by sulfurizing PhOH with salts of org. carboxylic or weak inorg. acids as catalyzers, is modified by using excess of PhOH and recovering the unsulfurized PhOH by distn

Catalytic reduction of anthraquinone compounds. I. G. FARBENIND. A.-G. (Julius von Braun and Otto Bayer, inventors) Ger. 511,576, Mar. 4, 1925. See U. S 1,751,670 (*C. A.* **24**, 2471).

1-Chloro-2-methylanthraquinone. W. SMITH, J. PRIMROSE, J. THOMAS and SCOTTISH DYES, LTD. Brit. 335,232, April 15, 1929. 2-Methylanthraquinone is chlorinated in oleum of strength not exceeding about 20% at temps. not exceeding 15° (the process being applicable as a step in the conversion of 4'-methyl-2-benzoylbenzoic acid into 1-chloranthraquinone-2-carboxylic acid without isolation of intermediate products, as described in Brit. 207,840 (*C. A.* **18**, 1504)). Examples and details of procedure are given.

Dihydroxyanthraquinone and its derivatives. JOHN W. ORELUP. U. S. 1,790,510, Jan. 27 Mixed *o*-chlorophenol and *p*-chlorophenol with phthalic anhydride are heated in concd. H_2SO_4 in the presence of H_3BO_3.

Anthraquinoneazines. PAUL NAWIASKY and LUDWIG EIFFLAENDER (to General Aniline Works). U. S. 1,790,109, Jan. 27. In forming *N*-dihydro-1,2,1',2'-anthraquinoneazines, a 2-aminoanthraquinone is subjected to the action of a caustic alkali melt in the presence of a salt of a lower aliphatic acid such as NaOAc together with an

alkali metal compd. of an alc. contg. at least 3 C atoms such as Na glycerate. Especially good yields are thus obtained.

Phenazones. I. G. FARBENIND. A.-G. (Arthur Wolfram, Emil Hausdörfer and Ludwig Schörnig, inventors). Ger. 513,206, Sept. 28, 1928. Phenazones are prepd. by the action of $AlCl_3$ on azobenzene and its homologs and substitution products having one *o*-position to each N atom unsubstituted. The reaction may be effected in the presence of fluxes and diluents, and in the presence or absence of air or other oxidizing agent. The reaction temp. may be 60–120°. Examples are given.

***o*-Hydroxybiphenyl.** GES. FÜR TEERVERWERTUNG M. B. H. and OTTO KRUBER. Ger. 513,027, May 17, 1929. Biphenylene oxide is treated with nascent H at a raised temp. Alkali metals need not be present (cf. Ger. 492,064 (*C. A.* **24**, 2475)). Thus, biphenylene oxide and steam superheated to 300° may be passed through a tinned iron tube filled with active C and heated to 850°.

Triazines. I. G. FARBENIND. A.-G. Brit. 334,887, June 10, 1929. 2,4-Bis(nitrophenyl)-6-halo-1,3,5-triazines (such as the 6-chloro deriv.) are made by treating a 2,4-di(nitrophenyl)-6-hydroxy-1,3,5-triazine with a P halide such as P oxychloride or pentabromide. The products may be used as *dye intermediates* or in making *pharmaceutical compds.* Cf. *C. A.* **24**, 4520.

Polyglucosans. F. HOFFMANN-LA ROCHE & Co. A.-G. Ger. 513,126, Feb. 29, 1928. Tetraglucosan and other polyglucosans are prepd by heating glucose with a quantity of an org. or inorg. acid at ordinary or reduced pressure or in an inert gas. A diluent may be present. Examples are given.

Chloranil. MARIA HEIMBERG NÉE KRAUSS. Ger. 511,209, April 6, 1929. Chloranil is prepd. by treating mononuclear isocyclic aromatic or hydroaromatic hydroxy compds. at a raised temp. with Cl and $HClSO_3$ together or in turn. The reaction is preferably effected in a medium of H_2SO_4 or oleum, and the $HClSO_3$ may be generated *in situ*, *e. g.*, by passing in HCl or by adding chlorides to the mixt. Examples are given.

Isoeugenol, etc. THOMAS S CARSWELL (to Monsanto Chemical Works). U. S. 1,789,352, Jan. 20. A mixt of alkyloxyisoeugenol and alkyloxyisochavibetol is subjected to such treatment (suitably by use of CaO or $Ca(OH)_2$) as to convert the mixt into the Ca salts of the isomers, and the Ca salts are sepd. (suitably by use of alc as a selective solvent) and the sepd. Ca salts are treated with acid.

Naphthostyrils. I. G. FARBENIND A.-G. (Richard Herz and Fritz Schulte, inventors). Ger. 511,212, May 12, 1926. Addn. to 441,225 and 504,342 (*C. A.* **24**, 5307). The methods of the prior patents mentioned are modified by using alk. earths instead of caustic alkalies The reactions are preferably conducted under pressure Examples are given. Cf. *C. A.* **24**, 5767.

Styrene. OMAR H. SMITH (to Dominion Rubber Co., Ltd.). Can. 308,122, Jan. 27, 1931. Styrene is produced by heating a mixt. of benzene and ethylbenzene to 600–750° in the presence of a dehydrogenating mixt. comprising ethylene chloride and S.

Porphyrins. HANS FISCHER. Ger. 511,319, Mar. 14, 1928. Porphyrins are prepd. by fusing halodipyrrylmethenes. An example is given. Cf. *C. A.* **25**, 716.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

FRANK P. UNDERHILL

Pectin. IV. Oxidation of pectin by Fenton's reagent and its bearing on the genesis of the hemicelluloses. A. G. NORMAN AND F. W. NORRIS. *Biochem. J.* **24**, 402–9(1930); cf. *C. A.* **24**, 133.—Pectin may be readily oxidized by means of Fenton's reagent. The reaction temp. must be 30–5°. The products of this reaction yield on hydrolysis galactose and galacturonic acid and resemble in appearance and general properties the structural hemicelluloses such as those obtained from wheat bran, beech wood and cereal straws. They are possibly polymerides contg. mainly galactose-monogalacturonic acid and galactose-digalacturonic acid, although the presence of other conjugated acids contg. galactose and galacturonic acid is not excluded. Hemicellulose may be formed in nature by the protracted mild oxidation of pectin. B. C. A.

Use of sulfur in biological chemistry. DE REY-PAILHADE. *Bull. soc. chim. biol.*

11, 1143–5(1929).—H_2S is evolved when certain biol. materials are mixed with S at 40°, even if the nitroprusside reaction is not given B. C. A.

Validity of blood-sugar determinations. VI, VIII. Variation in results obtained by deproteinization with tungstic acid and mercuric nitrate. VII. Sugar in the plasma. IX. Phenomenon of "mercurial dilution." G. FONTÈS AND L. THIVOLLE. *Bull. soc. chim. biol.* 12, 264–98(1930); cf. *C. A.* 24, 4816.—VI, VIII. Blood filtrates obtained by means of tungstic acid always give higher values for reducing sugars than those prepd. by Hg pptn. $Hg(NO_3)_2$ gives the same results on the tungstic acid filtrate as on the original blood filtrates, and these, after brief hydrolysis with dil. acid, become almost equal to the original values of the tungstic acid filtrate. The presence of a glucoside possibly accounts for these phenomena. Subcutaneous injection of adrenaline in dogs (1 mg. per kg. body-wt.) produces a rise in the glucoside content of the blood as well as in the dextrose content, while compression of the portal vein or injection of morphine does not affect it. Insulin decreases the amt. of reducing carbohydrate until, at the crisis, it is nonexistent. This sugar is entirely metabolized by yeast and living animal cells. VII. Rapid production of insulin hypoglucemia affects the plasma sugar only, although the sugar of the corpuscles is also affected after prolonged hypoglucemia. The sugar of the corpuscles acts as a reserve for that of the plasma. IX. If more than two vols. of water are added to whole blood or plasma before the Hg pptn., min. results for blood sugar are not obtained (mercurial diln.). This phenomenon persists after injection of insulin and in the filtrate from the tungstic acid pptn., and it appears to be due to some substance other than the reducing carbohydrate which appears in the tungstic acid filtrate. B. C. A.

Oxidation of some constituents of the body by activated charcoal. O. FÜRTH AND H. KAUNITZ. *Bull. soc. chim. biol.* 12, 411–2(1930); cf. *C. A.* 24, 871.—Amino acids of high mol. wt. are deaminized more readily than those of low mol. wt. Amides, some dipeptides, proline and histidine are not affected by charcoal. Phenolic substances are rapidly destroyed. Ordinary sugar charcoal is almost as active as animal charcoal. Deamination is in no case complete. B. C. A.

Normal antithrombin and its relation to the production of thrombin by cytozyme or chloroform. P. BORDET. *Compt. rend. soc. biol.* 100, 753–5(1929).—Serum activated by $CHCl_3$ can be inactivated by addn. of aged inactive serum, and it cannot then be activated by $CHCl_3$. Antithrombin is decomposed at 65° and is pptd. from soln. with $CHCl_3$. Thrombin originating from the action of cytozyme on serum is also decomposed by antithrombin. B. C. A.

Micelle changes produced by the addition of crystalloids to serum. G. CLUZET. *Compt. rend. soc. biol.* 101, 458–61(1929).—The viscosity and n of serum have maxima at p_H 5.5, but the max. cond. occurs at p_H 7.0. Electrolytes affect these phys. properties but sucrose and dextrose do not. B. C. A.

Electrostatic properties of human fibrinogen. G. VON FARKAS AND B. GROÁK. *Z. ges. exptl. Med.* 66, 590–613(1929).—The optimal p_H for pptn. depends on the method of sepn. and on the buffer mixt. used; the double optimum is ascribed to the presence of 2 proteins, both of which are coagulable. B. C. A.

Does the unipolarity of the air exert a physiological action? A. BELÁK, S. HOLIK AND ST. KELEMEN. *Z. Hyg. Infektionskrankh.* 111, 703–10 (1930).—A method is given for establishing the unipolarity of the atm. ions in a closed room. No effect could be observed on the blood pressure, pulse, respiration rate or phys. efficiency of the humans treated. RACHEL BROWN

The kinetics of ester hydrolysis by enzymes. III. The influence of indicator dyes on the activity of esterases. EUGEN BAMANN AND MARIA SCHMELLER. *Z. physiol. Chem.* 194, 1–13(1931); cf. *C. A.* 24, 3252.—Many indicators have an inhibitory effect on liver esterase. When the enzyme activity is detd. by titration after hydrolysis has taken place in the presence of indicator, there may be a considerable error unless a suitable choice of indicators has been made. Esterases from different sources show varying degrees of inhibition. The enzymes from sheep liver, human liver and horse liver show increasing inhibition by bromothymol blue in the order named. While the sensitivity of certain enzymes to light in the presence of fluorescent substances like eosin is non-specific, that of esterases to indicator dyes is specific. The inhibition depends on the reactivity of the substance with the enzyme, with the substrate or with the enzyme-substrate compd. The phthalein dyes especially, because of their lactone character, have a tendency to form complexes with the ester substrate. A suitable medium for comparing the effect of different indicators is a soln. contg. 100 cc. H_2O, 0.05 cc. $PrCO_2Me$ and 0.1–0.7 cc. of the enzyme prepn. representing 0.03–0.2 lipase units. Any considerable amt. of protein is to be avoided since it tends to adsorb the

dye and remove it from the sphere of action. The enzyme solns. were made by extg. the dry powd. liver, previously treated with MeAc and Et_2O, with 50 parts of 0.025 *N* NH_4OH, neutralizing with dil. AcOH and dialyzing. Addn. of 0.4 mg. of bromothymol blue or phenolphthalein to 100 cc. of the reaction system causes a decided inhibition of enzymic hydrolysis at p_H 6.8. The inhibition increases with increasing concn. of the indicator and with decreasing concn. of the ester. It decreases with increasing OH-ion concn., and at p_H 8.9 there is even an acceleration of hydrolysis. This is attributed to a transition from the lactone to the quinoid salt of the indicator. The p_H at which such change from inhibition to activation occurs varies with the turning point of the indicator. Bromocresol purple (dibromo-*o*-cresolsulfonethalein) in a concn. sufficient for indicator purposes (0.04 mg. per 100 cc.) is without influence on ester hydrolysis at p_H 6.8, but in greater concn. and at higher p_H it causes activation. A comparison of bromothymol blue with bromocresol purple (1 mg. per 100 cc.), both at p_H 7.0, showed 31% inhibition with the former and 23% activation with the latter. The decrease in inhibition by indicators in the presence of higher enzyme concn. is probably due to an increase in proteins which remove the dye by adsorption. Dyes other than those of phthalein structure may also be inhibitory. Rosolic acid gives an indistinct end point and *m*-$HOC_6H_4NO_2$ requires an inhibitory concn. *p*-$HOC_6H_4NO_2$ is not inhibitory but its turning point, p_H 6.0, is too far on the acid side. Neutral red is fairly satisfactory. For detn. of ester hydrolysis by liver esterase the choice of indicators rests with bromocresol purple (0.04 mg. per 100 cc.) and neutral red (0.3 mg. per 100 cc.). **IV. The behavior of esterases toward lactones.** *Ibid* 14–20.—Lactones, although they may be regarded as inner esters, are not hydrolyzed by esterases which attack the ordinary open-chain esters Butyrolactone, γ-valerolactone, cumarin and santonin in alk. medium show no appreciable hydrolysis by liver esterase prepns. which are reactive toward $PrCO_2Me$. On the contrary, they inhibit the cleavage of $PrCO_2Me$. Probably the lactone and the enzyme form a stable complex. The inhibition is proportional to the lactone concn. and inversely to the ester concn. By forming a complex with the enzyme the lactone diminishes the concn. of esterase-ester compd. and thus retards the ester hydrolysis. If the lactone ring is opened up, as in $MeCH(OH)CH_2CH_2CO_2NH_4$, the inhibitory effect is overcome. A. W. Dox

The nature of proteases. VII. Comparative investigations on the pepsin of cold- and warm-blooded animals. N. P. Pyatnitzkii. *Z. physiol. Chem.* **194**, 43–52 (1931); cf. *C. A.* **24**, 4796.—Gastric juice was obtained from frogs by the Smirnow method, which consists in ligating the stomach at the cardia and duodenum after the animal has swallowed numerous small pieces of cork, sewing up the abdomen, then removing the stomach after 24 hrs. and collecting the secretion. The latter contains 20–40 Gross pepsin units per cc., and digests 10 mm. of albumin in Mett tubes in 18 hrs. at 38°. The p_H varies between the limits 1.52 and 3.9. The gastric juice is relatively rich in combined HCl, deficient in free HCl and has a relatively high total acidity. The optimum p_H lies between 1.0 and 1.4 and coincides apparently with that of warm-blooded animals. The ext. of frog stomach is much less active than that of dog stomach. The pepsin of cold-blooded animals is evidently identical with that of warm-blooded animals. A. W. Dox

The action of arginase. VI. S. Edlbacher and H. Burchard. *Z. physiol. Chem.* **194**, 69–75(1931); cf. *C. A.* **22**, 96.—An arginase prepn. was obtained free from dipeptidase by dilg. a glycerol ext. of calf liver, treating the soln. with $Al(OH)_3$ and centrifuging. The soln. thus obtained was inert toward glycylglycine, leucylglycine, Witte peptone and gelatin at p_H 8, but vigorously attacked arginine. The arginase activity at p_H 9.2 was measured by detg. the liberated urea with urease. The dipeptidase-free arginase was examd. for its action on the dipeptide arginylarginine obtained by partial hydrolysis of clupein with 70% H_2SO_4 at 37°. This dipeptide contains 1 free NH_2 group as shown by the Van Slyke detn. After subjecting it to the action of purified arginase, the dipeptide yielded an amt. of urea corresponding to 85% of the theory for 1 arginine. The unpurified enzyme, however, which contained dipeptidase, yielded twice this amt. of urea. Arginase, therefore, attacks only 1 of the 2 guanidyl groups and leaves the peptide linkage intact. Contrary to statements in the literature both NH_2 groups of lysine react quantitatively in the Van Slyke detn. during 5 min. shaking at 20°. Under the same conditions ornithine yielded 88% of its total N. This behavior of lysine supports the theory that the free NH_2 of proteins represents the terminal NH_2 of the lysine component. The residual dipeptide of ornithine and arginine, resulting from the arginase cleavage of arginylarginine, contains 2 NH_2 groups which react in 5 min. in the Van Slyke detn. The action of arginase on only 1 of the 2 guanidyl groupings in arginylarginine is of especial interest in view of the recent

findings of Dauphinee and Hunter (*Biochem. J.* **24**, 1128) that the combined action of trypsin and arginase on proteins attacks only half of the arginine present. By the use of dipeptidase-free proteases it should be possible by this method to det. whether proteins contain arginylarginine, as does clupein, or whether the arginine groupings occur singly in the peptide chain. A. W. Dox

Hemoglobin preparation, fluorohemoglobin, papain cleavage of hemoglobin, and hemoglobin in pernicious anemia. Felix Haurowitz. *Z. physiol. Chem.* 194, 98–106 (1931).—The procedure previously described for the prepn. of cryst. methemoglobin depends on temp. and illumination and is difficult to control. Pure cryst. methemoglobin is obtained more easily and uniformly by 6–10 days' treatment of horse oxyhemoglobin with 5% EtOH at 37–40°. The transformation of methemoglobin into its F deriv. by treatment with 25% KF occurs very slowly, an equil. being reached in about 30 min. The previously described absorption curve does not correspond to this final stage and requires correction. The max. of absorption in the red lies at about 606 $m\mu \pm 1\ m\mu$. The action of papain-HCN on the blood pigment at p_H 5 resembles that of activated trypsin at p_H 9 and results in formation of a hemin proteose. In pernicious anemia only normal human hemoglobin is found, not the alkali-resistant fetal hemoglobin of the new-born. A. W. Dox

Biological action of Röntgen rays on the blood and spleen. I. Changes in the blood picture following x-ray radiation of the spleen. Shigetsugu Katsura. *Tôhoku J. Exptl. Med.* **16**, 241–59(1930).—The total leucocyte count of rabbits, and particularly that of the pseudo-eosinophiles, is larger in the afternoon. Following irradiation of the splenic area for several hrs. there is a slight decrease in the red cell count and hemoglobin, with a gradual return to normal within 6 weeks. There is a transitory leucocytosis (several hours); a slight leucopenia is observed several weeks later, reaching a max. in about 2 weeks. The pseudo-eosinophiles are particularly affected. There is a change in the Arneth formula following strong irradiation, presumably due to increased bone marrow function. **II. The changes in blood viscosity and serum protein following irradiation of the spleen.** *Ibid* 260–76.—Following strong irradiation of the splenic area ($^1/_2$ H. E. D.) there is a decrease in blood viscosity, a decrease in serum protein, but no change in serum viscosity. With weaker irradiation ($^1/_{25}$ H. E. D.) there is an increase in both blood and serum viscosity, but no change in the total protein. In both cases there is a relative increase in the globulin fraction which lasts for 2 weeks. Qualitatively similar results are obtained by irradiating the lower extremity, or the splenic area following splenectomy. The results are interpreted as due partly to blood diln. following strong irradiation, partly to a relative increase in globulin. H. Eagle

Pyrophosphate and cell structure. W. A. Engelhardt. *Klin. Wochschr.* **9**, 1550(1930); cf. *C. A.* **25**, 331.—Hemolysis by saponin, water or freezing is accompanied by an enormous acceleration in the decompn. of pyrophosphate into orthophosphate. H. Eagle

The oxidation-reduction potentials of living cells and their significance. Eugen Aubel. *Z. angew. Chem.* **43**, 939–43(1930).—The potential of aerobic cells varies according to the conditions, between +0.273 and —0.210 v. at p_H 7.0; the anaerobic cells between —0.050 and —0.490 v. at p_H 7.0. When it is possible to use electrodes, differences are established between electrodes of different metals and even electrodes of the same metal. The general curve, however, is the same in all cases and the limits are similar if the cells are uninjured. When the cells are autolyzed or compressed, more strongly neg. values are obtained. Their physiol. significance is naturally uncertain. In all expts. a definite reduction power was measured but it is doubtful whether a true oxidation-reduction potential in the thermodynamic sense is measured. The cell potential is dependent upon the cell synthesis. Russell C. Erb

The copper content of livers and liver extracts. G. N. Quam. *Proc. Iowa Acad. Sci.* **36**, 267–8(1929).—Stated in mg. per kg. beef liver has been found to contain 16 to 30 mg. for the adult and for calf liver McHargue has reported 161.3 mg. while Robscheit-Robbins and others reported 145 mg. Adult hog liver yielded an av. of 50 mg. per kg. A human fetal liver yielded 69.36 mg. per kg.; that of a still-born child, 28 mg.; while an adult liver (cirrhosis), 20 mg. Van Itallie and Van Eck reported 26.1 mg. per kg. for a still-born liver and White reported 19.1 mg. for an adult liver (sepsis). A sample of Armours live ext. (liquid) yielded 4.5 mg. per kg. of the original which calcd. to 0.5 mg. per kg. of the equiv. wt. of raw liver. Apparently only a small fractional part of the total Cu was recovered. Abbots liver ext. (dry) yielded 403 mg. per kg. of the original product or 25 mg. per kg. of the equiv. amt. of raw liver. Apparently little or no Cu was lost in the processing. Hart and others reported 160 mg. per kg. for their Ely Lilly and Co. product Lot No. 343 N. N. R. This disagreement

among investigators as to the potency of liver exts. and liver in the treatment of various types of anemia may be in some way assocd. with the lack of consistency in the Cu content of liver exts. W. G. GAESSLER

Ultrafiltrate in vivo. L. BRULL. *Compt. rend. soc. biol.* **99**, 1607–8(1928); *Physiol. Abstracts* **14**, 482.—On ultrafiltration *in vivo* the Cl, dextrose and nonprotein N pass fully through the filter; the mineral P and Ca are only in part obtained. G. G.

Cleavage of plasma proteins. Proteic sugar. H. BIERRY. *Compt. rend. soc. biol.* **101**, 20–2(1929); *Physiol. Abstracts* **14**, 338.—By heating to 120° in the presence of acids or alkalies, a cleavage of plasma proteins occurs. After prolonged action of potash, 1 or 2 non-reducing polysaccharides may be sepd. by fractional pptn., from which reducing sugars are produced. One of these is a hexose, another a biose. The latter is dextrorotatory and gives an osazone in concd. soln. G. G.

Plasma proteins and proteic sugar. H. BIERRY. *Compt. rend. soc. biol.* **101**, 544–6(1929); *Physiol. Abstracts* **14**, 649.—After cleavage of plasma proteins with potash it is possible to isolate a polysaccharide which is non-reducing. In presence of acids this is readily converted to reducing sugars. In particular, *d*-mannose and *d*-galactose may be obtained at a certain stage of the hydrolysis. It is not possible to say whether the 2 hexoses are combined or exist separately in the mol. G. G.

Protein sugar and animal species. H. BIERRY. *Compt. rend.* **191**, 1381–2(1930); cf. preceding abstract.—Protein sugar may vary quantitatively and qualitatively with the animal species. B. S. LEVINE

Displacement of iodine by irradiated cholesterol. E. ROUSSEAU. *Compt. rend. soc. biol.* **100**, 158–60(1929); *Physiol. Abstracts* **14**, 595; cf. *C. A.* **23**, 4953.—The displacement of I from KI by irradiated cholesterol in olive oil (1 hr.) is greater than that due to natural cod-liver oil. The appearance of acidity in the olive oil, with or without cholesterol, on irradiation may explain a part of the action in displacing I. The chem. power of oil plus cholesterol is distinctly greater than that of the oil alone. G. G.

Amylase protecting substances. I. Introduction and preliminary tests. HIROICHI NAKAMURA. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 521–2(1930).—The rate of digestion of starch at 50° by taka-diastase is practically const. between p_H 4.9 and 5.8. Solns. contg. 0.1% taka-diastase heated to 50° for 1 hr. were partially inactivated, the degree of inactivation varying from about 70% at p_H 4.7 to almost nil at p_H 5.8. More concd. solns. were inactivated to a greater degree under similar conditions. **II. Protective action of proteases.** *Ibid* 523–4.—The addn. of a small amt. of a protease to the taka-diastase soln. before partially inactivating it as previously described greatly decreased the effect of the heating. Papain and papayotin almost completely prevented inactivation; pepsin was less effective. Proteases previously boiled 20 min. were as effective as active proteases. No activating effect was observed **III. Protective action of proteins and their digestion products.** 524–6.—Peptone and the solns. obtained by digesting egg white, gelatin, or casein for various periods with pepsin or papain all partially inhibited the heat inactivation of taka-diastase at 50°, but had no activating effect. Digested gelatin solns. were most effective, casein least. L. E. GILSON

Carbohydrate complex of serum proteins and the clinical determination of bound sugar in the blood. CLAUDE RIMINGTON. *Nature* **126**, 882–3(1930); cf. *C. A.* **23**, 4714.—A further study of the carbohydrate complex obtained by hydrolysis of the proteins of horse serum has led to the conclusion that it is not a disaccharide but a trisaccharide, possibly polymerized, which contains 1 mol. of glucosamine assocd with 2 mols. of mannose and which is optically inactive. A similar complex has been isolated from ox blood and the mucoid of blood serum is under examn. for such substances. Contradictory observations of various authors regarding "bound sugar" of the blood are held to be due to the fact that alk. hydrolysis of the proteins leads to a non-reducing complex which is unattacked by enzymes while acid hydrolysis gives reducing substances. Removal of the protein with $Hg(NO_3)_2$ also ppts. glucosamine while phosphotungstic acid does not. R. C. HOCKETT

Catalytic splitting of casein. V. S. SADIKOV AND E. A. POZHILTZOVA. *Zhur. Prikladnoi Khim.* **3**, 895–904(1930); cf. *C. A.* **24**, 4062.—By using H_2SO_4 in place of HCl or H_3PO_4 in a higher concn. and by increasing the time of heating in the autoclave as compared with the usual methods cyclopolypeptides are easily isolated. A cyclotripeptide (cyclo-prolylprolylleucine), $C_{18}H_{28}N_3O_3$, was obtained in this manner. V. KALICHEVSKY

Sugars and their precursors in hen egg. H. BIERRY. *Compt. rend. soc. biol.* **101**, 579–80(1929); *Physiol. Abstracts* **14**, 654.—It is possible to set free reducing sugars from egg albumin. The sugar-forming substances are more abundant than is generally

recognized, and it is necessary to take account of this in expts. in autogenesis.
E. C. K.

Hexacosanol, a new alcohol of the fatty series C_{26}, obtained from the cortex of Amelanchier vulgaris Moench. J. RABATE. *Bull. soc. chim. biol.* **12**, 758–64(1930).—Eight g. crude hexacosanol ($C_{26}H_{54}O$), m. 77.5°, was obtained from 3 kg. dried material by extn. with alc. and ether, followed by sapon. and crystn. from ether. Aq ether was the best solvent for final purification. The acetate, iodide and hexacosanoic acid were prepd. and their mol. wts. detd.
C. G. KING

A method which enables one to follow the change in the number of particles in the process of formation and transformation of a colloidal solution. Application to blood serum. AUGUSTIN BOUTARIC. *Compt. rend.* **191**, 1332–4(1930).—B. assumes that the increase in the size of suspended spherical particles in the evolution of a colloidal suspension results from the process of (1) particles coalescing without any change in the H_2O content of the suspensoid, leading to a reduction in the no. of suspended spheres; (2) H_2O absorption by the suspended particles with a resulting swelling, leaving the original no. of spheres unchanged. By the application of the principle of Lord Rayleigh according to which a colloidal suspension possesses a coeff. of absorption (optic density) as per formula: $h = ANv^2 (n^2 - n_0^2)/(n^2 - 2n_0^2)$, where h = coeff. of absorption, A = a const. depending upon the wave length, N = no. of particles per unit vol., v = their vol., n = index of suspended substance, n_0 = index of the suspension media, B. is able to det. which of the 2 processes obtains in a given instance. The conclusion of Lecomte du Noüy that in the process of serum inactivation by heat the size of the suspended particles is increased without any change in their no. is corroborated.
B. S. LEVINE

The state of biochemical substances, proteins in particular, in anhydrous solution. JEAN LOISELEUR. *Compt. rend.* **191**, 1391–3(1930).—Biochem. substances, proteins in particular, are sol. in aliphatic acids and in the absence of water form true solns. The transition of a true soln. into a pseudo soln. may be brought about by the simple addn. of water, which interferes more dielectrically than as a chem. solvent. These properties are common to all biochem. substances, and the state of their soln. depends less upon their resp. constitution than upon their behavior toward the solvent.
B. S. LEVINE

Studies on urease. IV. The variations in ammonia in circulating blood through the action of urease. M. RIGONI *Arch. sci. biol.* (Italy) **15**, 342–5(1930); cf. *C. A.* **24**, 5359.—Supplementing observations referred to in earlier work, R. detd. NH_3 after introducing various doses of urease into the blood of the rabbit, using the Nash-Benedict method instead of the Folin-Denis method previously used. With this method, small variations in the NH_3 content of the blood were noted after the introduction of non-lethal doses of urease which escaped detection by the Folin-Denis method.
P. M.

Reversibility of protein coagulation. M. L. ANSON AND A. E. MIRSKY. *J. Phys. Chem.* **35**, 185–93(1931); cf. *C. A.* **24**, 1399, 3523.—Studies of the absorption spectra indicate that hemoglobin may be reversibly coagulated. It is probable that most proteins are reversibly coagulable.
FRANK URBAN

Adsorption in biology. R. FABRE. *J. pharm. chim.* [8], **11**, 529–39, 584–96(1930).—Typical examples are given of adsorption of gases, liquids and solids on charcoal, kaolin, etc.; its mechanism is explained on the basis of surface tension and elec. charges involved. The laws of Gibbs (cf. *C. A.* **4**, 2406) and Freundlich (cf. Trividic, *C. A.* **23**, 3613, 4121) are discussed. The importance of adsorption in biology is based on the great surface reactivity of the colloidal protein matter of the living cell. Detailed reference is made to the investigations of Hugounenq and Loiseleur on the nature of proteolytic enzymes (*C. A.* **18**, 109; **19**, 3493, 3499; **20**, 2105; **21**, 919), to those of Willstätter, *et al.* on enzyme purification, including the sepn. of the pancreatic enzymes (*C. A.* **16**, 938, 3320; **20**, 2339) based on the work of Michaelis (*C. A.* **3**, 920); also the purification of insulin (*C. A.* **17**, 3884; **18**, 541, 1730, 1731, 2351) and of vitamins by adsorption (cf. Seidell, *C. A.* **12**, 562; **16**, 3113). Many examples of the pharmacol. and toxicol. application of selective adsorption are quoted, *e. g.*, Ehrlich's work; Wittgenstein and Krebs (*C. A.* **20**, 1465), Sbarsky and Subkowa (*C. A.* **20**, 1276, 3737), Billard (*C. A.* **21**, 2007; **24**, 3261), Vincent (*C. A.* **20**, 3187) and Binet and Fabre (*C. A.* **24**, 4865).
S. WALDBOTT

Membrane equilibria and their application in biology. L. AMY. *J. pharm. chim.* [8], **12**, 79–89(1930).—A clear exposition of the law of Donnan and its application to the phenomena of osmotic pressure, swelling of gels, viscosity, membrane potential and equilibria in blood.
S. WALDBOTT

Studies on the oxidation-reduction power of tissues. I. Introduction. R. FABRE AND H. SIMONNET. *J. pharm. chim.* [8], **12**, 97–101(1930). **II. Studies on the perfused liver.** *Ibid* 193–213; *Bull. soc. chim. biol.* **12**, 777–99. **III. Studies on liver pulp.** *J. pharm. chim.* [8], **12**, 253–66(1930); *Bull. soc. chim. biol.* **12**, 800–14.—A record of expts., with conclusions (*C. A.* **24**, 4816–7). Also cf. *C. A.* **15**, 3119; **21**, 2708, 3373; **24**, 1876. S. WALDBOTT

Effect of ethylene upon the hydrolysis of salicin by emulsin. D. T. ENGLIS AND F. A. DYKINS. *J. Am. Chem. Soc.* **53**, 723–6(1931).—The fact that C_2H_4 hastens coloration of many fruits and vegetables gave rise to the belief that its effect might be associated with the activation of the enzyme responsible for the hydrolysis of many glucosides. For this reason a study was made of its influence upon the rate of hydrolysis of salicin by emulsin. The rate of hydrolysis was followed by polarimetric observations and detns. of reducing sugar. No acceleration of the reaction was observed in favor of the treated samples over the controls. The results are in accord with the idea that C_2H_4 does not directly affect the activity of enzymes but acts indirectly through its effect upon the living matter. C. J. WEST

Heat-coagulable protein from gelatin. S. E. SHEPPARD, J. H. HUDSON AND R. C. HOUCK. *J. Am. Chem. Soc.* **53**, 760–5(1931).—Gelatin prepd. from calf-skins usually contains a small amt. (less than 1%) of a heat-coagulable protein as an impurity. The protein approaches albumin (egg albumin and serum) in N content (about 14%). Its org. S content is considerably higher than that of gelatin (0.8 compared to 0.24%). Its isoelec. point lies at about p_H 4.0. It is suggested that the so-called "insol." gelatin of various investigators is identical with this protein impurity. C. J. WEST

C—BACTERIOLOGY

CHARLES B. MORREY

Do significant physiological strains of Bacillus amylovorus (Burr.) Trev. exist? FRANK L. HOWARD. *Proc. Iowa Acad. Sci.* **36**, 105–10(1929).—On a physiol. basis sufficient differences have probably not been demonstrated, as yet, to warrant the assumption that strains of *Bacillus amylovorus* occur. This species might be considered

exceptionally const. when the widespread sources of the cultures are considered. A short bibliography is appended. W. G. GAESSLER

Physiological behavior of the propionic acid group of bacteria. SARA E. KENDALL AND C. H. WERKMAN. *Proc. Iowa Acad. Sci* **36**, 111(1929).—The group comprises a no. of species of bacteria producing large quantities of EtCOOH from carbohydrates. The generic diagnosis of the group is: *Propionibacterium*, Orla-Jense, 1909. Gram-pos., non-sporulating, non-motile short rods showing marked morphological variation in acid media or when grown under aerobic conditions; normal growth anaerobic. Cultures are catalase-pos. Carbohydrates, glucosides and alcs. are attacked with the production of EtCOOH, AcOH and CO_2. The species are differentiated on the basis of sugar fermentation, nitrate reduction, pigment production and morphology. A key to the species is given with a description of each. W. G. GAESSLER

The production of propionic acid from pentoses by Propionibacterium pentosaceum. C. H. WERKMAN, R. M. HIXON, E. I. FULMER AND C. H. RAYBURN. *Proc. Iowa Acad. Sci.* **36**, 111-2(1929).—*Propionibacterium pentosaceum* attacks pentoses (xylose, arabinose) with the production of EtCOOH and AcOH. The medium employed was dried yeast (Harris Lab) 10 g., K_2HPO_4 1 g. $CaCO_3$ 5 g., pentose 15 g., H_2O 750 cc. The medium was brought to boiling, cooled and adjusted to p_H 7.1 electrometrically. It was then sterilized for 15 min. at 20 lb. pressure. The inoculum consisted of 25 cc. of a 10-day culture of *P. pentosaceum* in Sherman's $NaC_3H_5O_3$ medium. Incubation was at 30° for 10 days. The xylose employed was prepd. from corn cobs by a method of acid hydrolysis. In addn. to the pentoses a no. of other fermentable substances were employed to furnish comparative data. Small quantities of a substance, apparently succinic acid, were found in all cases, probably derived from the proteins. Both EtCOOH and AcOH are produced from xylose and arabinose by *P. pentosaceum*. Only EtCOOH is produced from glycerol by this organism in significant quantity. W. G. GAESSLER

Virulence of hemolytic streptococci. I. The influence of oxygen on the production of glossy variants. E. W. TODD. *Brit. J. Exptl. Path.* **11**, 368-92(1930).—Virulent cultures of hemolytic streptococci are degraded to glossy, avirulent variants by long-continued subcultivation on aerobic agar. This change is due to natural selection of the variants by bacterial peroxide and the following factors contribute to the process of selection: (*a*) The glossy variants of certain strains are more resistant to inhibition by peroxide than the virulent forms. (*b*) Virulent colonies produce more peroxide, and therefore suffer earlier autosterilization than glossy colonies. The process of selection does not occur in anaerobic cultures when no peroxide is found; it is accelerated by adding reagent H_2O_2 to the medium and by using media which preserve peroxide. Natural selection of glossy variants is prevented and virulence is maintained if accumulation of bacterial peroxide is prevented by adding catalase to the agar used for subcultivation; on the other hand, peroxidase does not appear to accelerate, and possibly tends to retard, the natural selection of glossy variants by peroxide. D—BOTANY

THOMAS G. PHILLIPS

A method for the growth of leguminous plants under bacteriologically controlled conditions. E. W. HOPKINS, P. W. WILSON AND E. B. FRED. *J. Am. Soc. Agron.* **23**, 32–40(1931).—The seeds are sterilized by immersion *in vacuo* in 1:1000 $HgCl_2$ soln. The seeds were then sprouted after which all transferring, planting and growing were carried out in a transfer chamber which is described. J. R. ADAMS

The chemical composition of some pollens. E. ELSER AND J. GANZMÜLLER. *Z. physiol. Chem.* **194**, 21–32(1931).—Microchem. analyses of alder, pine and hazel pollen gave the following values, resp.: H_2O 7.11, 7.45, 2.33; dry substance 92.89, 92.55, 97.77; fat 23.55, 14.59, 8 81; protein 23.44, 12.55, 16.19; invert sugar 4.60, 1.61, 6.43; sucrose 0, 5.82, 3.95; catalase +, +, +; amylase +, —, +; sucrase +, —, —; total ash 3.78, 2.88, 4.53; SiO_2 0.90, 0.20, 1.01; K_2O 1.85, 0.94, 2.46; CaO 0.339, 0.252, 0.353; Fe_2O_3 0.315, 0.040, 0.114; P_2O_5 1.13, 1.39, 1.37; MgO 0, 0, 0; Cl 0, 0, 0. The significant findings are the entire absence of Mg and Cl, the absence of sucrase from 1 variety, and the differences in enzyme makeup of the 3 varieties. The sucrase content is insignificant compared to that of honey. Pine pollen is avoided by bees because of its high cellulose content. The protein and the mineral constituents are important nutrients for the bees, but the carbohydrates are negligible in comparison to the honey. The wax of the comb is not derived from pollen but is a specific product of the bees' metabolism. A. W. DOX

Quercetin in Magnoliaceae and its distribution in the vegetable kingdom. TH. WEEVERS. *Proc. Acad. Sci. Amsterdam* **33**, 778–85(1930).—The petals of *Magnolia yulan* var. *Soulangiana* contain quercetin (I), which was not found at all (or only in traces) in the petals of *M. stellata*. Neither I nor quercitin was found in the leaves and twigs of *M. yulan*. When the petals were frozen at —5° and then melted, they turned brown. Since I could then be isolated from them, I is not the chromogen which on oxidation gave the brown color. There was no indication of a connection between anthocyanins and I in the metabolism of the petals of *M. yulan*. Along with a marked increase in anthocyanin during petal development, the quantity of I increased. The presence of I in different plants does not indicate a closer genetic relationship between these species. LOUISE KELLEY

Relation of nutrients to perithecial production under ultra-violet irradiation. F. L. STEVENS. *Philippine Agr.* **19**, 265–72(1930).—The production of the sexual stage in fungi, *Glomerella cingulata* and *G. lagenarium*, was studied in relation to nutrients and ultra-violet light. Irradiation with ultra-violet light greatly stimulated conidial production in certain strains. Sucrose, levulose and maltose strongly favored mycelial growth; raffinose, lactose and galactose favored it to a less extent. Those sugars that most stimulated growth also increased perithecial production most upon irradiation. Certain strains never produced perithecia under any circumstances. Various vitamins caused excessive development of the mycelium but had no effect on the production of perithecia. Certain strains which had never been known to form perithecia before did so after irradiation if either pepsin, raffinose or $MgSO_4$ was added to the nutrient. This result was particularly striking with added pepsin. A. L. MEHRING

The fermentable principle in the tubers of Asphodelus. C. NEYRON. *Bull. sci. pharmacol.* **37**, 539–48, 603–13(1930).—The morphology of the tubers of *Asphodelus microcarpus, albus* or *ramosus* is described. Exts. were observed by the polariscope before and after hydrolysis with acids and with sucrase. From 8 to 10% of the carbohydrates is sucrose. The rotatory power of exts. of bulbs of varying age and at different seasons of the year and of the rhizome has been studied. A. E. MEYER

The necessity and function of manganese in the growth of Chlorella sp. E. F. HOPKINS. *Science* **72**, 609–10(1930); cf. *C. A.* **20**, 3177; **21**, 2489; **22**, 610.—It is shown that Mn is essential for the growth of a unicellular green alga, *Chlorella sp.* The growth of the alga is studied in comparative culture solns. in the presence and in the absence of Mn. Without Mn, only a few mg. of dry felt is obtained; at p_H 7.0, the increase due to Mn is 17-fold and at p_H 8.0 about 170-fold. It is also shown that Mn is toxic to the plant as the amt. added is increased. Since Mn and Fe are both

essential to plant growth, it is suggested that the function of the Mn is to control the ratio of Fe^{++} to Fe^{+++} in the culture or in the cell. N. M. NAYLOR

The classification of plant juices: nitrate concentration in large and small leaves. DONALD E. FREAR. *Science* **72**, 634–5(1930).—A method is described for securing plant juices used for the detn. of nitrate N by the phenoldisulfonic acid method (*C. A.* **18**, 725). The plant tissue, which has been frozen, is thawed and the juice expressed by hydraulic pressure. To an aliquot sample of the clear juice is added 5 cc. of satd. Ag_2SO_4 soln., 1 cc. of *N* $CuSO_4$ soln., and 0.2 g. $Ca(OH)_2$ and the mixt. made to a vol. of 100 cc. It was found that the colloidal ppt. formed by the above reagents absorbs the coloring matter of plant juices so that a suitable soln. is obtained for the nitrate N test. The midrib of the leaves contains more nitrate than the rest of the leaf and since the proportion of midrib to leaf varies with the size of leaf, it is thought to be more consistent to make detns. for nitrate N on leaves from which the midrib has been removed. N. M. NAYLOR

Studies on toxic action. I. Preliminary observations on the swelling and shrinkage of plant tissue in solutions of toxic substances. WALTER STILES. *Protoplasma* **11**, 349–81(1930).—Disks of potato, 2.2 cm. in diam. by 1 mm. thick, were immersed in various solns. for a definite time, then removed, superficially dried and weighed. The change in wt. was considered a measure of the toxicity of the solute when compared with results obtained with distd. water. A reduction in rate of swelling was produced by $Hg(CN)_2$, $CuSO_4$, quinine-HCl and $CHCl_3$. An initial acceleration of swelling was produced by H_2SO_4, osmic acid, $HgCl_2$ and the primary aliphatic alcs. The order of decreasing toxicity is quinine-HCl, $HgCl_2$, $CHCl_3$, $CuSO_4$ and EtOH. M. H. S.

Distribution of moisture, dry matter and sugars in the maturing corn stem. F. A. WELTON, V. H. MORRIS AND A. J. HARTZLER. *Plant Physiology* **5**, 555–64(1930).—The percentage of "residual dry matter" (*i. e.*, the total dry matter minus the total sugars) and that of sucrose were, in general, larger in the upper part of the corn stem than in the lower part. The percentage of moisture was larger in the lower part of the stem. The percentage of "residual dry matter" and of sucrose increased and the percentage of reducing sugars and of moisture decreased progressively from the tasseling stage to maturity. The total amt. of "residual dry matter," moisture and sugars per segment (consisting of an internode and the node above) reached a max. in the region of the second, third or fourth segment and decreased rapidly toward the upper part of the plant. The lowest 4 segments, constituting about 0.25 of the total length of the stem, contained over 50% of the total amts. of these constituents of the stem.
WALTER THOMAS

Adolf Engler, Botanist, 1844–1930. A. BECHERER. *Schweiz. Apoth. Ztg.* **68**, 671–2(1930).—An obituary. S. WALDBOTT

The action of x-rays on the development of plants. MME. S. LALLEMAND. *Thesis*, Strasbourg, 1929; *J. pharm. chim.* [8], **12**, 45–6(1930).—A systematic study is made of the effect of x-rays on the development of seeds, dry or in process of germination, of *Panicum miliaceum, Lepidium sativum, Brassica napus, Triticum sativum, Lens esculenta, Phaseolus vulgaris*, also of the bulb of *Allium cepa*. The study of the biol. effects of graduated doses of x-rays led to the observation of "*radiophylaxy*," *i. e.*, the application to a cell of a small dose of x-rays protects it against a new but much stronger irradiation, but only after the lapse of a certain time between the 2 exposures. If the cells are kept at a low temp. where metabolism is much retarded, radiophylaxy does not take place. Thus the latter is a function of the physiol. activity of the cell, independent of radiosensitivity. S. WALDBOTT

A contribution to the iodine question. J. HANSEN. *Tierernähr.* **1**, No. 1, 119–24 (1929).—A general article on the metabolism of I in cows. Numerous tables are given to show the effects of I on milk and fat production. RUSSELL C. ERB

Energy metabolism of sheep. E. G. RITZMAN AND F. G. BENEDICT. N. H. Agr. Expt. Sta., *Tech. Bull.* **43**, 3–23(1930).—By the surface-area method the heat production was detd. on 115 sheep. For these body measurements the formula $S = 0.124\ W^{0.561}$ was used, in which S equals surface area in sq. m. and W equals the live body wt. in kg. The technic involved and a description of the app. are not given in this bulletin

but will be published separately. Standard metabolism signifies a measure of the animal's heat production while standing during 3 or 5 half-hr. periods beginning 24 hrs. after the last food intake. Rams and sucking lambs showed highest basal metabolism values. Energy requirements of sheep are extraordinarily high at birth and during the early part of the suckling period, but drop rapidly thereafter and by the end of the fourth month of life reach a level below which there is only a relatively small further decrease, due purely to advance in age. C. R. FELLERS

Estrus-producing hormone in the urine of cattle during pregnancy. C. W. TURNER, A. H. FRANK, C. H. LOMAS AND C. W. NIBLER. Univ. Missouri Agr. Expt. Sta., *Research Bull.* **150**, 5–43(1930).—A study is reported of the rate of secretion of the estrus-producing hormone in the urine of 45 dairy cows and 32 beef cows. The urine was collected every 2 hrs. by a new method of induced micturition. A 24-hr. collection period was the min. period during which a representative sample of urine could be obtained. The estrus-producing hormone was extd. from the urine by shaking 2 l. of the urine with 20–50 cc. of pure olive oil, allowing it to settle in a separatory funnel, centrifuging the oil to clarify it, and assayed by the method of Allen and Doisy (*C. A.* **17**, 3929); spayed, white rats were used. During the advance of the stage of gestation, the daily secretion of the hormone began at a low level and increased gradually until the time of parturition. The course of the hormone secretion during pregnancy can be represented by the equation $H = Ae^{Kt}$, where H is the daily hormone secretion at any day during pregnancy t, A (93.0) is the initial daily level of hormone secretion, K (0.0126) is the rate of increase of the hormone, and e the base of natural logarithms. The increasing secretion of the hormone during pregnancy is probably required for the normal development of the mammary glands. Little difference was noted between Jersey and Holstein cattle, though dairy cows as compared with beef types showed greater hormone secretion after 100 days following gestation. The vol. of urine increases for the first 100 days, then gradually declines until parturition. Changes in age and milk production did not perceptibly influence the vol. of urine secreted. Full bibliography. C. R. FELLERS

Comparative studies on the osmotic resistance and permeability of the red blood corpuscles of mother and child. K. J ANSELMINO AND F. HOFFMANN. *Arch. Gynakol.* **142**, 649–61(1930).—By the use of the method of partial hemolysis it has been shown that in the blood of the new-born child 40–50% of the blood corpuscles are osmotically less resistant than those of the mother and 50–60% are more resistant. The interval between the beginning and end of hemolysis is greater with the blood corpuscles of the child and may exceed 3 atms. of osmotic pressure while with the blood corpuscles of the mother hemolysis is complete with 2 atms., which is also the normal value in non-pregnant women. The cell membrane of the red blood corpuscle is made up of a mosaic-like arrangement of lipoid and protein phases in a supporting stroma. The permeability of the lipoid phases of the cell membrane is greater in the new-born child than in the mother as is shown by the more rapid entrance in the corpuscles of the child of arabinose, galactose and glucose, substances which are known to enter through the lipoid phase. Substances such as erythritol, a tetrose, that enter through the protein (globin) phase enter with equal rapidity the corpuscles of the blood of both mother and child which indicates that there are no differences in the protein phase of the cell membranes. HARRIET F. HOLMES

The Reid-Hunt reaction and pregnancy. II. H. EUFINGER AND H. WIESBADER. *Arch. Gynakol.* **142**, 662–7(1930); cf. *C. A.* **23**, 4731.—The resistance of white mice to a lethal dose of acetonitrile is heightened by a previous series of injections of serum from a woman in the later stage of pregnancy. The hormone from the anterior lobe of the hypophysis increases the acetonitrile resistance enormously and the increase of resistance does not seem to be dependent on the abs. quantity of the hormone. Preparatory treatment with ovarial hormone also increases the acetonitrile resistance, though to a far less degree. The increase of the acetonitrile resistance, therefore, cannot be attributed solely to the increased presence in the serum of pregnant women of thyroxine-like substances, but it is probable that an increase of the hormone of the anterior lobe of the hypophysis and perhaps an increase of ovarial hormone are of marked importance. HARRIET F. HOLMES

Iron storage in splenectomized rabbits. F. S. FOWWEATHER AND C. J. POLSON. *Brit. J. Exptl. Path.* **11**, 362–8(1930).—It is shown by means of parallel expts. on intact and splenectomized rabbits, that the absence of the spleen does not affect the storage of Fe, the principal site of Fe storage being the liver. Confirmation is obtained of previous expts. with the intravenous administration of Fe. Failure to secure an adequate reservoir of Fe in the lungs precluded observations on the possible function of

the spleen in the transfer of Fe from lungs to liver. A new feature in these expts. was the appearance in the liver of a non-ferruginous pigment which had the staining reactions ascribed to hemofuscin by Mallory, Parker and Nye (*C. A.* **16**, 3339). Since the only new factor was the addn of mangels to the diet, it is possible that this feed may be responsible for the appearance of the pigment. HARRIET F. HOLMES

Sex differences from the standpoint of biochemistry. TETSUTORO TADOKORO. *Med. Bull. Univ. Cincinnati* **6**, 1-31(1930).—Acidic muscle proteins of female animals compare with those of males as follows: higher in ash and P content, lower p_H, less specific rotatory power, greater quantity of combined HCl, less development of the acidity of muscle fibers in neutral salt solns., greater histidine N, less arginine, a greater no. of acetyl groups in acetylated proteins and greater N content. The physicochem. characteristics of oryzenin of glutinous rice closely resemble those of female proteins. The same chemistry must occur in both plant and animal cells. Methods of sex diagnosis must be based on the following chemisms: the female body cells are richer in fat, contain proteins of higher acidity, are superior in reduction and are more anaerobic in respiration. MARY E. LEAR

Investigations on the reciprocal relation intervening between the secretory function of the stomach and the chlorine equilibrium and the acid-base metabolism of the organism. II. The influence of the mobilization of tissue chloride by novasurol and of the period of low chloride intake on gastric secretion. ANASTAZY LANDAU AND JERZY GLASS. *Med. Doswiadczalna i Spoleczna* **12**, 313-56(1930).—Injection of 2 cc. of novasurol causes an increased secretion of Cl in the urine which is reflected in a noticeable manner on the secretory function of the stomach and in the blood. One hr. after a meal contg. alc. with a simultaneous injection of novasurol, the plasma Cl slowly falls as compared with the amt. in the blood after a meal with alc. alone. The corpuscular Cl is thus not affected. The Cl content of gastric secretion is increased after novasurol, and so is the acidity (phase 1). There follows then a fall in Cl content and in the free and total acidity (phase 2). During a period of low Cl intake the gastric juice is not appreciably altered. Alc. has the same effect as before. After 2 hrs. the curve of Cl secretion is lower than the normal. The Cl index in the period of low Cl intake is greater than normal. The secretion in the urine is also above the normal. Only in the 2nd phase does the Cl fall. It is suggested that in a period of low Cl intake the stimulation of the secretory function of the stomach produces a compensatory mobilization of tissue Cl. G. H. W. LUCAS

Contribution to the study of the physiological variations and the internal secretions of the pancreas. E. ZUNZ AND JEAN LA BARRE. *Arch. Intern. Physiol.* **33**, 142-58 (1930).—The introduction of HCl into the duodenum of dogs stimulates the flow of pancreatic juice. This increased flow is accompanied by a decrease in blood sugar if the adrenals have been removed from the system. These expts. indicate a relation of the internal and external secretions. C. M. MCCAY

Study of the acid secretion of the stomach. I. Secretion of the isolated mucus of the frog stomach. Technic. Action of histamine and pilocarpine. G. DELRUE. *Arch Intern. Physiol.* **33**, 196-216(1930).—The mucous membrane of the stomach of a frog can be easily sepd. and clamped in position so that it forms the dividing wall of 2 cells Ringer's soln. can be placed in these cells and the p_H measured at regular time intervals. Under such conditions the membrane remains alive. It develops an acidity in the one cell that is similar in magnitude to that of the intact stomach. The acid secretion is stimulated by treating the membrane with histamine or pilocarpine. C. M. MCCAY

Experimental investigation on the fate of bilirubin introduced into the blood vessels. I. Changes of bilirubin concentration in the blood vessels and its limit of excretion into bile, urine and cerebrospinal fluid. SANETOSHI SAIKI. *Japan. J. Gastroenterology* **2**, 203-12(1930).—Bilirubin injected into the circulation of rabbits and dogs rapidly disappears from the blood plasma. It passes into the bile and urine very easily. Dog kidneys are more permeable than those of the rabbit. C. M. MCCAY

The significance of the liver glycogen in the liver function. I. The pigment excretion from the liver in cases where the liver glycogen is diminished. TANESABURO IKUSHIMA. *Japan. J. Gastroenterology* **2**, 213-9(1930).—The rate of excretion of azorubin S by the bile was measured after the injection of 0.5 cc. of 1% soln. per kg. of body wt. into the blood stream of rabbits. The time of the first appearance in normal animals is about 3 min. The total excretion requires 60-75 min. in winter and 75-90 min. in summer. After the glycogen of the liver is decreased by fasting, or by the injection of phlorhizin, strychnine or adrenaline the time of excretion may extend to 2 hrs. The pigment excretion function of the liver falls when the glycogen content

decreases. **II. The pigment excretion from the liver in cases where the liver glycogen is increased.** *Ibid* 220–5.—The glycogen was increased in the livers of different rabbits by feeding glucose, fructose, galactose, saccharose, maltose and lactose. Increase of glycogen content produces acceleration in the rate of dye excretions. C. M. McCay

Experimental studies on the halogen excretion from the liver. I. Studies on the chlorine-excreting portion of the liver. Yoshimasa Maruno. *Japan. J. Gastroenterology* **2**, 231–8(1930); cf. *C. A.* **24**, 1431.—Rabbits were injected intravenously with 5 cc. of 10% NaCl soln. per kg. body wt. Alterations in the Cl of the blood and bile were measured in a series of samples. The blood Cl increases after the injection and then drops to the normal after 2–3 hrs. The bile Cl attains a max. in 15–30 min. and remains above normal after 23 hrs. Injury to the liver by means of CCl_4, P or liver emulsion disturbs the Cl excretion. Since blockading the stellate cells with India ink produces no effect, the Cl excretion must be through the parenchymatous cells. C. M. McCay

Some observations made by means of the double gastro-duodenal tube, with particular reference to the opening and closing function of the pylorus. Niro Endo. *Japan. J. Gastroenterology* **2**, 239–46(1930).—A double tube permits the collection of both gastric and duodenal samples at the same time. The test meal of 50 cc. of whole milk permits the use of a small food vol. By the use of this technic it was shown that the more the acid secretion of the stomach is accelerated, the more delay results in the passage of stomach contents into the duodenum. The upward flow of duodenal contents is rarely found. No definite relation exists between the acidity of the gastric juice and the quantity of duodenal juice. C. M. McCay

Biological and chemical studies of extracts of the anterior lobe of the pituitary. E. A. Spaul and W. W. Myddleton. *J. Exptl. Biol.* **8**, 30–43(1931).—AcOH exts. of the anterior lobe of the pituitary stimulate metamorphic activity of tadpoles. Part of the active substance is pptd. by an I soln. (6.35 g. I_2 and 15 g. KI per l.). Similar AcOH exts. of other tissues such as liver and exts. of anterior lobes with other solvents do not give the same ppt. The metamorphic factor is destroyed rapidly by trypsin and slowly by pepsin. It is reduced by boiling. C. M. McCay

The phosphate content of the anterior lobe of the pituitary. E. A. Spaul and W. Myddleton. *J. Exptl. Biol.* **8**, 44–54(1931).—There is a rough correlation between the phosphate P of the I ppt. and its metamorphic activity. The active factor is insol. in EtOH, $CHCl_3$ and Et_2O. The melanophore stimulant has no relation to phosphate content. There is a small amt. of phosphate pptd. from posterior-lobe exts. C. M. McCay

The physicochemical theory of sex. Ph. Joyet-Lavergne. *Compt. rend.* **191**, 682–4(1930).—Hormone and chromosome theories of sex have serious difficulty in explaining the metabolic aspect of sex. Chromosomic and other morphological characteristics are manifestations of a phys.-chem. equil. of cell constituents, which must be more thoroughly understood to explain the question of sex. J. G. McNally

The influence of various kinds of agricultural work upon the alkali reserve of the blood of horses. I. The physiology of work in agricultural draft-animals. W. Schaper. *Z. Tierzucht. Zuchtungsbiol. Tierernahrung* **20**, 79–96(1930).—The values for alkali reserve of the blood of resting horses are subject to considerable variations at different hrs. on the same day and from one day to another. No significant changes occur in the mean values as a result of work. There appears to be a relationship between the nature of the ration and alkali reserve. Body temp. was found higher after work in 16 cases, lower in 9 and unchanged in 5. L. A. Maynard

Studies concerning the hemoglobin of the blood of healthy swine. Hans von Falck. *Z. Tierzücht. Zuchtungsbiol. Tierernähr.* **20**, 97–120(1930).—The hemoglobin content of the blood of new-born pigs is very high—15 to 16 g. This value, which is higher than that of the mother, drops quickly during the first few days, then more slowly, reaching a min. during the second week. It then commences to rise and reaches a value between the 5th and 8th week which is comparable to that of full-grown hogs. The hemoglobin values of sows in advanced pregnancy and of sows nursing litters are markedly lower than those of sterile sows and sows in early pregnancy. L. A. Maynard

The unitary versus the multiple hormone theory of posterior pituitary principles. John J. Abel. *J. Pharmacol.* **40**, 139–69(1930).—Methods are briefly described for the prepn. of a colorless powder having all the physiol. properties of the international standard pituitary powder with an increase in potency of 50 to 60 times the standard. Impurities make up 50% of this powder, chiefly proteins of an albumose-like character. It contains also a cryst. org. compd. contg. N. Boiling with 0.25% AcOH causes

hydrolysis of the unitary product, with production of physiologically active cleavage products. A. believes that "pitressin" is a mixt. of 3 active principles (vasopressor, melanophore and antidiuretic) with inert materials, and some unhydrolyzed unitary product. "Pitocin" contains chiefly the oxytocic cleavage product. It is estd. that the unitary product if pure would have an activity of 100 times that of the standard powder and that each of the 4 cleavage products if isolated in the pure state would have an activity 300–400 times that of the standard powder. Some evidence for this is presented. C. RIEGEL

Iron and manganese in the human organism. G. CHEVALIER. *Thesis*, Paris 1929; *J. pharm. chim.* [8], **12**, 480(1930).—In physiol. organs, the Fe and Mn contents do not differ much from an av. for each organ; muscle has the least Fe or Mn; liver has the most Fe or Mn; the ratio of Fe to Mn varies with each organ. In pathol. organs, the av. values for Fe are more variable; but the Mn content is rather const., being about parallel with, although slightly lower than, that in healthy tissues. S. W.

Chemistry of the hormones. F. LAQUER. *Klin. Wochschr.* **1930**, No. 3; *Therap. Ber.; Schweiz. Apoth. Ztg.*, **68**, 581–3, 601–3(1930); cf. *C. A.* **22**, 4599; **23**, 1437.—A review of the present state of our knowledge of glands and their hormones. S. W.

H. GIDEON WELLS

Local specific immunity of the skin. M. A. KUSCHMARJEW. *Z. Immunitäts.* **65**, 517–23(1930).—The intracutaneous injection of anatoxin produces a local immunity of the skin against diphtheria toxin. The immunity is sp. and depends on the satn. of the cell receptors which are sensitive to toxin. The grade of immunity produced in the skin is proportional to the concn. of anatoxin or its content of sp. haptoform groups. JULIAN H. LEWIS

The time of the appearance of isohemagglutinating properties in the human blood. M. A. DYCHNO AND G. D. DERTSCHINSKY. *Arch. Gynäkol.* **142**, 740–9(1930).—The blood was examd. for agglutinins and agglutinogens in 14 fetuses aged 3–7 months, 76 new-born infants and 24 children aged 2 days to 18 months. The agglutinogens appear early in intrauterine life and were well developed in a fetus of $3^1/_2$ months. Agglutinins were found for the first time in an almost full-term child. At the end of the third week of extrauterine life the agglutinins had disappeared from the serum of the child. The agglutinins reappeared at the second month. Toward the end of the second year the blood had the characteristics of adult blood. It is probable that the agglutinins present in the serum of the child at birth are the agglutinins of the mother, which gradually disappear and are replaced by the child's own agglutinins. The group reaction of the blood of 8.8% of the girls and 19.04% of the boys was different from that of the mother but in no case was any effect noted on the development or weight of the child. HARRIET F. HOLMES

The effect of injury on cellular permeability to water. B. LUCKÉ AND M. MCCUTCHEON. *Arch. Path.* **10**, 662–70(1930).—The unfertilized egg of the sea urchin, *Arbacia punctulata*, was used as a cell in which injury can readily be recognized and permeability to water accurately measured. It was found that injury (induced by high temp. and by anisotonic solns.) causes a marked increase in cellular permeability to water, and that this increase in permeability can be correlated with the degree of injury. HARRIET F. HOLMES

Experimental subacute amyloid nephrosis in rabbits. E. M. BUTT. *Arch. Path.* **10**, 859–68(1930).—Amyloid nephrosis may be produced in rabbits by subcutaneous injections of Mn chloride. The production of the lesion of the kidney depends on giving Mn chloride over a long period of time, thus making it necessary to regulate the dose to the individual tolerance of the animal. This may be done by following the daily weights and the detn. of albumin in the urine. HARRIET F. HOLMES

Further observations upon electric charge in its relation to hemolysis and phagocytosis. J. C. BROOM AND H. C. BROWN. *Brit. J. Exptl. Path.* 11, 305–10(1930).—The amt. of complement fixed by sensitized bacteria depends on the concn. of NaCl present. $K_4Fe(CN)_6$ inhibits serum hemolysis *in vitro*, and *in vivo* its administration to mice exerts a protective action against a lethal dose of a hemolytic serum. This salt also markedly interferes with the phagocytosis of bacteria. It is probable that all these effects are dependent upon the relative elec. charges of the reacting components.
HARRIET F. HOLMES

Tar cancer in mice. II. The condition of the skin where modified by external treatment or diet, as a factor in influencing the cancerous reaction. A. F. WATSON AND E. MELLANBY. *Brit. J. Exptl. Path.* 11, 311–22(1930).—The carcinogenic activities of a sample of coal tar were increased when each of its periodical applications to the skin of the mouse was preceded by treatment of the skin with certain fluid fats or fatty substances. A petr.-ether ext. of the tissues of mice was found to be particularly effective in producing this acceleration. In addn. to a relatively larger no. of skin tumors and their accelerated growth, these increased carcinogenic activities were reflected in the greater no. and development of the assocd. nodules situated in the lung tissues. The carcinogenic activities of the tar were also increased if the exptl. mice were maintained on a diet contg. a high proportion of fat in the form of butter. Under these conditions the coats of the animals assumed a characteristic fatty condition which probably facilitated the periodical absorption of the tar. The preliminary treatment of the skin with petr. ether under certain conditions was found to produce the opposite effect to that produced by the local treatment of the skin with suitable fluid fats. This was shown by a decrease of skin tumors and lung nodules, together with inhibited growth in the former. HARRIET F. HOLMES

The theoretical carbon dioxide dissociation curve in acid-base disturbance of childhood. N. MORRIS AND S. GRAHAM. *Brit. J. Exptl. Path.* 11, 322–8(1930); cf. *C. A.* 24, 1667.—The capacity of the blood for holding CO_2 depends upon 2 factors, the available alkali and the degree of buffering. The relative importance of these 2 factors in maintaining acid-base equil. is revealed by the theoretical dissocn. curve described by Barcroft, *et al.* (*C. A.* 20, 2878). In the blood of a normal child the theoretical dissocn. curve agreed with that actually detd. In congenital pyloric stenosis the CO_2 dissocn. curve is definitely hypercapnic. A theoretical dissocn. curve constructed from the blood of an infant showing very marked symptoms was much higher and flatter than normal, which indicates that the blood contains much more than the usual amt. of CO_2 at any given tension. The slight flattening of the curve is due to the low degree of buffering, while the height of the curve is the result of the large amt. of available alkali. The theoretical dissocn. curve from the blood of a child showing symptoms of salicylate poisoning was definitely lower than normal and the lowness is due solely to the diminution in the degree of buffering as the amt. of available alkali is well within normal limits. HARRIET F. HOLMES

The secretion of mucus by the colon. H. FLOREY. *Brit. J. Exptl. Path.* 11, 348–61(1930).—Application of agents capable of causing cell damage calls forth a secretion from the goblet cells of the colon. This secretion might be caused either by the direct action of the noxious agents on the goblet cells or by the liberation of some chem. substance which then stimulated the goblet cells Tests with histamine (which is active on the skin), acetylcholine, adenosine and peptone solns. have failed to give evidence that they stimulate mucus production from the goblet cells. Exts. prepd. from colonic mucosa did not have an observable influence in stimulating mucus production. It appears, therefore, that the goblet cells directly react to the insult of the noxious agent in contradistinction to the accompanying vascular reaction which, judging from the results on skin, is due to the liberation of some histamine-like body.
HARRIET F. HOLMES

The index of nucleic phosphorus in normal and neoplastic tissues. A. H. ROFFO AND P. PILONI. *Neoplasmes* 9, 201–10(1930).—By the use of the technic of Javillier and Allaire (*C. A.* 19, 3100) detns. were made of the total P, nucleic P and lipoid P in the blood and organs of normal rats and of rats with tumors and in the tumors. The nucleic P in the blood of a normal rat is lower than that in the blood of a tumor rat, while the nucleic P in the liver or spleen is very much less than that in tumor tissue. These differences appear more marked if the indices (nucleic P × 100)/total P and (nucleic P × 100)/lipoid P are considered. The following values were obtained for nucleic P/total P: liver 4.36, spleen 4.35, sarcoma 19.6 and carcinoma 31.67, and for nucleic P/lipoid P: liver 12.91, spleen 23, sarcoma 70 and carcinoma 152. The results are explained as in relation to the nuclear contents of the tissues. The nuclear

content is known to be high in neoplastic tissue, but there seems also to be a hyperfunction with increased mitotic activity. HARRIET F. HOLMES

The chlorine content and the chlorine distribution in the blood and their relation to acid-base equilibrium. A. LANDAU, J. GLASS AND S. KAMINER. *Compt. rend. soc. biol.* **101**, 594–6(1929); *Wiener Arch. inn. Med.* **20**, 375–428(1930).—The Cl content of the blood and its distribution in plasma and corpuscles were studied in 10 convalescents and in 64 patients with various pathol. conditions. The normal Cl content of the blood shows little variation and is as follows: Cl of the total blood 2.7–3.02 g. per l.; Cl of the plasma 3.4–3.62 g.; Cl of the blood corpuscles 1.7–1.95 g. The Cl index of the blood corpuscles or the ratio of Cl concn. of the blood cells to Cl concn. of the plasma is 0.47–0.55. In pathol. conditions the variations are more marked and the amplitude of variation in the blood corpuscles is nearly twice as large as those in the plasma. In 14 cases the Cl content of the blood corpuscles was greater than normal and in all these cases there was acidosis. In 45 cases without acidosis this condition was found only once, in a case in which there had been a long-continued administration of chlorides in considerable amount. The rise of the Cl index of the blood corpuscles over normal values was noted 20 times, in 16 of which there was acidosis. The rise of the Cl content of the blood corpuscles over 2.30 g. per l. and the rise of the Cl index of the blood corpuscles over 0.65 were found only in cases with most severe acidosis and the prognosis is extremely unfavorable in these cases. There is, however, no strict parallelism between the lowering of the alkali reserve in cases of acidosis and the degree of shifting of Cl from plasma to blood corpuscles. In 7 cases in spite of pronounced acidosis the Cl content of the blood corpuscles and the Cl index were not increased. H. F. H.

The cause of anaphylactic shock. V. YELIN. *Arch. Path. Anat.* (Virchow's) **278**, 35–41(1930).—A series of histological changes develops in the organism following the parenteral introduction of protein, including, particularly, an increased glycogen deposition in the liver. In anaphylactic shock, produced by reinjection of the same protein, a sudden passage of glycogen from the liver, and possibly also the muscles, into the blood occurs. Anaphylactic shock is the result of a glycogenemia and consequent glycogen poisoning. E. R. LONG

Placental transmission of foreign proteins in rabbits. FRANCES E. HOLFORD. *J. Immunol.* **19**, 177–216(1930).—Horse hemoglobin was not found to pass the rabbit placenta, but egg albumin horse or beef serum, the pseudo-globulin fraction of beef serum, and the globulin fraction of horse serum, injected into pregnant rabbits near term, in a no. of instances passed the placental barrier in quantity sufficient for demonstration in the serum of the fetus. These facts may explain the occasionally observed sensitization of the fetus *in utero* to foreign protein. E. R. LONG

The relationship between complement and opsonin. Experiments with Congo red. J. GORDON. *J. Immunol.* **19**, 303–5(1930).—Congo red and similar dyes prevent the bactericidal and hemolytic (complement) activities of normal serum, but a serum the complement of which has been inactivated by Congo red is still able to exert opsonic activity. E. R. LONG

Molecular movement, viscosity and agglutination. STEPHEN WENT. *J. Immunol.* **19**, 347–56(1930).—The viscosity of the dispersing medium affects the Brownian movement of bacteria greatly. With a certain degree of internal friction mol. movement ceases. The intensity of this movement depends on the abs. temp. Bacteria may flocculate spontaneously if the viscosity of the medium is increased to a certain degree. The sensitiveness in this relation depends on the amt. of bacterial surface. Media of high viscosity hinder the bacterial agglutination caused by immune sera; this is an effect on the first phase of immune agglutination, *i. e.*, the process of adsorption of the immune bodies. E. R. LONG

The relation of the bacterial precipitin reaction to the Ramon flocculation phenomenon. ELIZABETH LEE HAZEN. *J. Immunol.* **19**, 393–403(1930).—Flocculation in mixts. of filtrate of *C. diphtheriae* and antitoxin is not limited by agglutination types of the organism serving for toxin production. Pptn. in mixts. of toxic filtrate and agglutinating serum is restricted to agglutinating types. The property in the toxic filtrate essential for flocculation with antitoxin is destroyed at 60°, when this temp. is maintained 0.5 hr., whereas the property essential for pptn. of agglutinating serum withstands 85° for 1 hr. Removal of the bacterial antibody from antitoxic serum by adsorption of the serum with bacterial exts. does not prevent subsequent flocculation of the serum with the toxic filtrate, whereas the agglutinating serum treated in the same manner no longer ppts. with the toxic filtrate. The Ramon reaction is probably due to interaction between toxin and antitoxin and not between bacterial precipitinogen and precipitin. E. R. LONG

The dialyzability of proteins. ARTHUR F. COCA. *J. Immunol.* **19**, 405–10(1930).—The dialyzability of the excitants of atopic hypersensitiveness in egg white reported by W. Jadassohn (*Schweiz. med. Wochschr.* **1926**, No. 27) is confirmed. Dialyzates were prepd. by the use of 3 different membranes, the collodion sac, the air bladder from fish and the parchment diffusion shell. With the aid of specific antisera and chem. methods the dialyzable excitants were shown to be native proteins, and these proteins proved to have antigenic capacity. E. R. LONG

The heat stability of the diphtheria toxin. K. ANDO AND H. NISHIMURA. *J. Immunol.* **19**, 465–71(1930).—The heat sensitiveness of diphtheria toxin depends on its p_H when heated. The more acidified the toxin is, the more heat stable it is. Diphtheria toxin is practically destroyed by heating to 80–90° for 30 min., but some toxicity remains even after 30 min. boiling. When acidified to a p_H of 2.0 before boiling the toxin preserves $^1/_{1000}$ to $^1/_{700}$ of its original toxicity after boiling for 30 min. E. R. L.

Experiments on the concentration of antipneumococcic and antimeningococcic horse sera. KENNETH GOODNER. *J. Immunol.* **19**, 473–84(1930).—During immunization of horses against the meningococcus and pneumococcus there is generally an increase in the serum of a euglobulin of low soly. The antibody of the immune serum is assocd. with this protein, particularly with its least sol. fraction. This fact makes it unnecessary to conc. the protein as a whole. E. R. LONG

The action of formaldehyde on diphtheria toxin. WM. E. BUNNEY. *J. Immunol.* **20**, 47–59(1931).—Toxoid formation does not appear to be the result of direct action of HCHO on diphtheria toxin, but seems to be due to the action of a compd. resulting from the reaction between HCHO and the amino group of an amino acid. A method for making toxoid on this principle is suggested. It consists in concg. low-grade toxins and then diluting in a glutamic acid soln. to which HCHO has been added. E. R. LONG

Advantages and disadvantages of the buffered diluent for diphtheria toxin. WM E. BUNNEY AND BENJAMIN WHITE. *J. Immunol.* **20**, 61–70(1931).—The buffered diluent of Glenny, Pope and Waddington (*J. Path. and Bact.* **31**, 133(1928)) dissolves diphtheria toxin pptd. by acid, and preserves toxicity and flocculation value for at least 10 months in cold storage. It is not a practical diluent for Shick toxin prepns. E. R. LONG

A new diluent for diphtheria toxin in the Shick test. WM. E. BUNNEY. *J. Immunol.* **20**, 71–84(1931).—A 2% soln. of peptone contg. 0.85% NaCl and 0.5% phenol maintains the toxicity of certain diphtheria toxins dild. to 0.25 M. L. D. per cc. for at least 2 months. E. R. LONG

Biochemical investigation of the blood in cases of experimental disturbance of liver function. I. Liver function and carbohydrate metabolism. TSUNEJIRO [illegible]DA *Japan. J. Gastroenterology* **2**, 191–202(1930).—The blood sugar of rabbits was detd. by the method of Bang before and after injury to the liver. The livers of various rabbits were impaired by feeding $CHCl_3$, CCl_4 and yellow P. The blood sugar increases in the early period of poisoning and falls below the normal in later stages. Injury through *Schistosomum japonicum* causes the blood sugar to rise to a max. about 30 days after infection. At the time of the animal's death on the 70th day the values were normal Injury to the liver by Röntgen ray irradiation produced a rise in blood sugar for 3 days. Partial hepatectomy decreases blood sugar from the beginning. Ligation of the common bile duct causes an initial increase followed by a decrease. One or two rabbits were used for each expt. The fluctuations regarded as significant are frequently close to the author's normal. C. M. MCCAY

The biological diagnosis of gout. PEDRO ESCUDERO AND ADOLFO ESCUDERO *Semana méd.* (Buenos Aires) **1930**, II, 1945–54.—The patient is kept on a diet free from purines for 10 days and the av. of purine elimination in the urine is detd. On the test day, 100 g. beef ext contg. 1 g. purine substances is given. Patients suffering from gout retain between 50 and 85% of the purine. The method of Deniges for the detn. of uric acid, directions for the diet and clinical records are given. A. E. MEYER

A large calculus formed within the prepuce. COUILLAUD. *J. pharm. chim.* [8], 12, 31–4(1930).—In a case of phimosis affecting a native of Bamako, W. Africa, a hard calculus weighing 645 g., of about 10 yrs.' formation was removed. The urine contained CaC_2O_4, Ca phosphate and uric acid. The stone consisted of 2 concentric layers (*A*, *B*), resp., 4 and 3.5 cm. thick, and an outer (*C*) and an inner nucleus (*D*), wt. 4 g. CaC_2O_4 was absent throughout. *A* contained $CaCO_3$ and Ca phosphate, also $MgNH_4PO_4$, but no uric acid or urates (murexide test). Results in *B* were the same except that $MgNH_4PO_4$ was more pronounced. This was chiefly present in *C* which contained

little Ca, but also some uric acid and Na urate. *D* contained traces of $MgNH_4PO_4$ and of $CaCO_3$, but showed the murexide test abundantly. S. WALDBOTT

H—PHARMACOLOGY

A. N. RICHARDS

Cutaneous absorption of phosphorus. F. ZERNIK. *Z. ges. exptl. Med.* **70**, 1–15 (1930).—The absorption of yellow P through the skin of guinea pigs depends on the solvent. P. could be demonstrated in the skin 5 days after application. A 1% soln. of dichloroamine in CCl_4 inhibited the cutaneous absorption of P. Rules for handling P by men are recommended. F. L. DUNN

Variations of the glucemia level in dogs under the influence of an injection of colloidal silver and adrenaline. H. GNOIŃSKI. *Med. Dosawiadczalna i Spoleczna* **11**, [illegible]ench 117–8)(1930).—Intravenous injection of colloidal Ag causes hyperglucemia on the av. of 35% and at the same time a diminution of hepatic glycogen. Adrenaline alone causes hyperglucemia on the av. of 70%. Injections of colloidal Hg and adrenaline cause hyperglucemia on the av. of 43%. About the same hyperglucemia is caused by subcutaneous injection of adrenaline 4 hrs. after the injection of colloidal Ag. The hyperglucemia after the injection of colloidal Ag is apparently not caused by the stopping of the reticulo-endothelial system. J. KUČERA

The tolerance of normal subjects to levulose. Factors influencing the variations in rise in blood sugar. NORMAN JOLLIFFE. *J. Clin. Investigation* **9**, 363–80(1930).—In normal subjects the max. blood sugar following oral ingestion of 30 to 50 g. of levulose rarely exceeds 115 mg. %. A rise to 125 mg. % was considered abnormal. Tests on convalescent patients and triplicate tests on normals showed no significant variation. A level of blood sugar above 95 to 110 mg. % seems to stimulate a sugar-storage mechanism which rapidly lowers the blood sugar. The rapidity of disappearance of the blood sugar probably depends on the glycogen-forming ability of the sugar used. J. B. B.

Studies in congestive heart failure. VI. The effect of overwork and other factors on the potassium content of the cardiac muscle. J. ALFRED CALHOUN, GLENN E. CULLEN, GURNEY CLARKE AND T. R. HARRISON. *J. Clin. Investigation* **9**, 393–403(1930); cf. *C. A.* **25**, 736.—The water content of the ventricular muscles of patients dying of congestive heart failure was not changed There was diminished K of the right ventricle in pneumonia and massive collapse and in myocardial insufficiency, resulting in pulmonary congestion. In hepatic and systemic edema from myocardial insufficiency there was decreased K of the right ventricle. The cause of loss of cardiac K was not edema, but rather overwork which is the predisposing factor to cardiac fatigue and failure. **VII. The effect of overwork on the potassium content of skeletal muscle.** J. ALFRED CALHOUN, GLENN E. CULLEN AND T. R. HARRISON. *Ibid* 405–8.—"Overwork of the muscles of one leg of a dog, produced by stimulation of the sciatic nerve,

usually leads to a diminished content of K in these muscles as compared with those of the opposite unstimulated leg." J. B. BROWN

The treatment of oriental sore with berberine acid sulfate. B. M. DAS GUPTA. *Indian Med. Gaz.* **65**, 683–5(1930).—A 2% soln. of the salt is used; 2 cc. of this is injected into several points, thoroughly to infiltrate the area. FREDERICK G. GERMUTH

Tryptophan and histidine are hematogenous amino acids. GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend.* **191**, 1088–90(1930).—Subcutaneous injections of the two acids, tryptophan and histidine, into rabbits and dogs cause an increase of 1,040,000 in erythrocytes and 6:100 in hemoglobin, after one day. The use of both (1:2) is superior to the use of either alone. Rats fed on a diet deficient in these 2 acids show a marked decrease in hemoglobin index. It is suggested that they be called hematogenous amino acids. MARY E. LEAR

Hypoglucemic action of bulbs of Allium cepa L. MAURICE-MARIE JANOT AND JEAN LAURIN. *Compt. rend.* **191**, 1098–1100(1930).—Exts. of certain bulbs, when injected subcutaneously into rabbits, show an action similar to that of insulin. Exts. stabilized in solid CO_2 give better results than those treated with boiling 95% alc. Analysis shows mannose and glucose, 26.5 g. per 100 in terms of glucose; pyrocatechuic acid; nitrogenous and S compds. Sugar may be responsible for the failure to establish glucemic equil. MARY E. LEAR

The influence of amino acids on the glycogen mobilization in the toad liver through adrenaline. YOICHIRO TANIUCHI. *Folia Pharmacol. Japon.* **10**, No. 1, 64–99(1930). Lately Abderhalden and his pupils have reported that the so-called optone, as well as certain amino acids, strengthen the adrenaline action on heart activity, vessel contraction and intestinal function. These substances appear to sensitize the nerve endings in the organs to adrenaline. Perfusion expts. have been performed on toad livers with glycocoll, tryptophan, histidine and cystine in certain concns. of adrenaline to det. the glycogenic effect. The sugar was estd. by the Hagedorn method. Glycocoll and tryptophan in concn. 1–20,000 or 40,000 are weak in sugar production, while histidine and cystine are actionless. Each amino acid in certain concns. strengthens more or less the sugar mobilization of the adrenaline; histidine and cystine are especially active. Livers perfused with Ringer soln. contg. histidine or cystine an hr. before adrenaline is added show remarkable adrenaline action; glycocoll and tryptophan do not. The combined effect of 2 amino acids is much weaker than their action separately and is also weaker on the adrenaline action. The sugar mobilization does not parallel the concn. of amino acid or the combination with adrenaline. All observations on toad livers could be paralleled by the action on blood vessels in warm-blooded animals. H. G. W. LUCAS

The detoxication of adrenaline through the reticulo-endothelium apparatus. II. TORANOSUKE UEMORI. *Folia Pharmacol. Japon.* **11**, No. 1, 42–56, Breviaria 3 4 (1930); cf. *C. A.* **25**, 351. In connection with earlier expts. with India ink, U has investigated the effect in rabbits of electrargol Clin and lithium carmine. Intravenous injection of these intensify remarkably the adrenaline sensitivity. Repeated injections give an increased effect After loading the reticulo-endothelium cells with these colloids, the adrenaline action by the mesenteric vein is much greater than by the ear vein The silver colloid and lithia carmine strongly influence the reticulo-endothelium cells in their detoxication of adrenaline. These cells in the liver play an important role. The Congo red index after electrargol rises insignificantly; *i. e.*, the Congo red accumulative possibility of these cells after being filled with the silver colloid remains almost unchanged **III.** *Ibid* 57–74, Breviaria 4 5. —Artificial perfusion of fresh rabbit liver through the portal vein with adrenaline-contg. Ringer soln shows that a considerable decrease in adrenaline has taken place in the perfusion fluid. The loss is very small if the rabbits are first injected intravenously with India ink, electrargol or lithia carmine. Repeated injections are most effective. The liver has a conspicuous detoxicating effect on adrenaline through its reticulo-endothelium system. Perfusion through the liver artery also shows a loss of adrenaline but it is small compared to the loss through the portal vein. Colloids do not affect the loss of adrenaline so much when perfusion is made through the artery. Perfusion of the spleen shows that much adrenaline is removed After preliminary intravenous treatment with the colloid, the adrenaline detoxication is greatly hindered. The reticulo-endothelium of the spleen stands in intimate relationship with the adrenaline inactivation by this organ. G. H. W. LUCAS

The relationship between the vomiting, blood sugar and uric acid regulation center from the pharmacological standpoint. I. The influence of emetics on the vomiting and blood sugar. MOKKIU MUN. *Folia Pharmacol. Japon.* **11**, No. 1, 75–83, Breviaria 5(1930).—Apomorphine-HCl, Cu sulfate, emetine-HCl, wine of antimony and erycon

have been employed in a series of comparative expts.; they were injected subcutaneously in dogs. The rapidity with which vomiting is produced is in the order given above. Emetine produces more frequent vomiting, and wine of antimony the least. In reduction of blood sugar, the series is thus—emetine-HCl, antimonial wine, Cu sulfate, erycon and apomorphine-HCl. Apparently simultaneously with stimulation of the vomiting center by emetica in the dog the blood center is also affected and the blood sugar falls. G. H. W. LUCAS

The influence of synthetic β-(1-piperidyl)ethyl acetyltropate (navigan) on the blood sugar mobilization in the liver. KIKUO TODA, YOICHIRO TANIUCHI AND MITSUTAKA NAKANO. *Folia Pharmacol. Japon.* **11**, No. 2, 15 Breviaria(1930).—It is generally assumed that atropine depresses the parasympathetic nerve ending app. exclusively. It appears that this view has not sufficient grounds. In many organs it acts antagonistically to adrenaline, and appears to fatigue sympathetic nerve endings. In the toad liver, it depresses the sugar mobilization after adrenaline. Expts. with navigan in perfusion of toad livers show that it slightly increases the sugar content and that when it is injected together with adrenaline, it depresses, on the other hand, the sugar mobilization of the adrenaline. This latter action is stronger the longer the foregoing adrenaline stimulation continues. This is in harmony with earlier data of other investigators and supports their assertion that atropine is a fatigue poison of sympathetic endings. G. H. W. LUCAS

Studies on chronic morphine poisoning. I. The blood picture of morphinism. MASASUE SUO. *Folia Pharmacol. Japon.* **11**, No. 2, 127–43, Breviaria 9(1930).—The blood of morphine addicts compared with that of normal persons shows a lower red count, which leads one to assume the presence of an anemia. In normal persons as well as in addicts and addicted dogs, a leucocytosis appears 30–60 min. after a morphine injection. The increase in lymphocytes is greater than in polynuclear neutrophiles. This change in the leucocytes is only transient and becomes normal in 90–120 min. In addicts and addicted dogs which show a leucocytosis, the percentage of lymphocytes is greater than that of the other leucocytes. During the period of abstinence in the addict, the increase in leucocytes is due to the no. of polynuclear neutrophiles. **II. The sedimentation of the blood corpuscles in the morphine addict and the addicted dog.** *Ibid* 143–152, Breviaria 10.—The sedimentation of the red cells in the addict and the addicted dog is much more rapid than normal. In the addict, the sedimentation is more rapid in the period of habituation than in the abstinence period. Withholding of the morphine doses only retards the sedimentation. This retardation increases in the abstinence period. In the withdrawal period, the sedimentation is slower in well-nourished patients than in emaciated ones. It is also slower in patients who have had small daily doses than in those who have had large daily doses. G. H. W. LUCAS

The study of Leonurus sibericus L. II. Pharmacological study of the alkaloid "Leonurin" isolated from Leonurus sibericus L. SEIKO KUBOTA AND SEIKICHI NAKASHIMA. *Folia Pharmacol. Japon.* **11**, No. 2, 159–67, Breviaria 11–2(1930); cf. *C. A.* **25**, 771.—The M. L. D. of leonurin injected subcutaneously per g. body wt. of frogs is between 0.0004 and 0.0006. In mice when injected it produces irritation, convulsions and respiratory paralysis. The heart continues to beat for some time. The M. L. D. per g. body wt. is between 0.0006 and 0.0007, injected intravenously in a cat. It produces a temporary fall in blood pressure, which may be followed by a slight rise. On the excised frog heart, a small dose has a stimulant action, but a large dose a depressant one. Perfusion expts. on toads showed that the alkaloid contracted blood vessels. Similar results were obtained on rabbits. Small doses in a cat act as a respiratory stimulant, quickening the frequency and magnifying the amplitude. Excessive doses produce respiratory paralysis. The alkaloid acts on motor nerve endings as curara does. On isolated intestine it appears to stimulate the musculature directly. The tonus of the excised uterus is increased and the movements are magnified. Intravenously injected in a rabbit it produces a marked diuresis. It has a hemolytic action on rabbit blood in concns. up to 1/1000. G. H. W. LUCAS

The influence of some drugs of the quinine group on the growth in vitro of cultures of fibroblast. SEIICHI SEMURA. *Folia Pharmacol. Japon.* **11**, No. 2, 168–80, Breviaria 12(1930).—The influence of quinine, quinidine, cinchonine, cinchonidine and optochine on the growth *in vitro* of cultures of fibroblast has been measured. Fibroblast cultures 1–2 months old from the ventricle of chick embryo were used in the usual cover glass method. The nutrient medium was chick plasma with an addnl. vol. of embryo tissue fluid. Fixed and stained prepns. of normal cultures were made as controls at the same time. The above-mentioned drugs were poisonous and their poisonous effect varied directly with their concn. High concns. completely inhibited growth; the tissue de-

generated rapidly and died. The cells showed irregular polygons or rounded-off forms in the growth zone. In the cytoplasm appeared an aggregation of fat granules with more or less small vacuoles. Optochine was the strongest poison; cinchonine and cinchonidine were the weakest. G. H. W. LUCAS

The drugs employed in Chinese medicine as antidiabetica. NORIYUKI SUGIHARA. **III. Experimental investigation on the influence of the drugs employed in Chinese medicine as antidiabetica on the blood sugar of rabbits.** PIUNGKI MIN. *Folia Pharmacol. Japon.* **11**, No. 2, 181–7, Breviaria 13(1930); cf. *C. A.* **25**, 741.—Alc. exts. of *Bupleurum falcatum, Lycium chinense, Fritillaria verticillata* and *Anemarrhena asphodeloides* increase the blood sugar rapidly. The max. is reached in ½ to 1 hr., after which there is a gradual decrease to normal values in 5–6 hrs. Alc. exts. of *Cannabis sativa, Pachyma coccus, Astragalus membranaceus, Morus bombycis, Atractylis ovata, Phellodendron amurense, Pueraria hirsuta* and *Rehmannia lutea* act to increase the sugar and then to decrease it. After 2–3 hrs. a gradual hyperglucemia occurs. G. H. W. L.

The influence of various conditions on the resorption of sodium salicylate from the pleural cavity, as well as the absorption path of this drug. MASAYOSHI OGAWA. *Folia Pharmacol. Japon.* **11**, No. 2, 188–201, Breviaria 13–4(1930).—Sodium salicylate (0.1 g. per kg.) was injected into the right pleural cavity of a rabbit, and at various intervals after the injection the salicylate content of the serum was estd. in blood taken from the jugular vein, according to the method of Herissey. The resorption of salicylate from the pleural cavity decreases after section of the phrenic nerve on the side in which the injection was made. This is more distinct after double-sided phrenectomy. However, after phrenectomy on the other side, there is practically no effect. It is thought that the spreading of the injected soln. due to the respiratory movement plays an important role. This is quite evident after phrenectomy where there is a decrease in resorption when respiration is decreased on the side injected. Disturbance of the circulation of the lung also influences the resorption. When an animal is curarized and artificial respiration is employed, the rate of resorption is increased with an increase in respiratory frequency. After a unilateral closed pneumothorax the rate of resorption on the same side is depressed and on the other side is increased. This shows clearly that resorption and blood circulation on the damaged side are decreased, while on the uninjured side, they are strongly compensated. G. H. W. LUCAS

The fluctuation of cholesterol, calcium and sugar pictures in blood of rabbits poisoned with thallium. SHIGEYOSHI KOYANAGI. *Folia Pharmacol. Japon.* **11**, No. 2 202–13, Breviaria 14–5(1930).—The relationship between Tl and the endocrine system has been investigated frequently, but no definite conclusions have been reached. It is known that the metabolism of cholesterol, Ca and sugar is closely related to the inner secretion functions. Expts. performed by K. show that the cholesterol content of the blood after repeated subcutaneous administration of Tl undergoes a more or less marked rise which is most noticeable during the falling out of the hair. There is also a rise in free cholesterol and cholesterol esters, particularly of the latter. Following subcutaneous or intravenous injections of Tl, the Ca falls in varying degrees. Intravenous administration of Tl results in hyperglucemia. Subcutaneous injection shows two different forms, one in which there is a tendency to hyperglucemia and one in which an initial fall is superseded by a rise in blood sugar. In Tl-poisoned rabbits, the hyperglucemia resulting from adrenaline is more or less weakened. G. H. W. LUCAS

Studies upon the action of certain amino acids upon the isoelectric point of human serum. F. VLÈS AND A. DE COULON. *Compt. rend.* **191**, 1166–8(1930).—Previous repts. have shown the isoelec. point of the plasma can be altered by the injection of amino acid mixts. Cancers in mice have been cured by such injections. Six cancer patients were injected with a mixt. of alanine, proline and cystine. The amt. used ranged from 4 to 14 g. Before the injections the isoelectric points of the plasmas ranged from p_H 8.3 to 11. After the injections they attained minima from p_H 5.0 to 8.0 in the course of 1–2 months. Single detns. and not minimal values are given for the isoelec. points before the injections. C. M. MCCAY

The formation of compounds between lead and lipoids in the organism. The behavior of the fatty acids of the liver in lead poisoning. G. ORESTANO. *Arch. sci. biol.* (Italy) **15**, 204–14(1930).—See *C. A.* **24**, 4863 PETER MASUCCI

The pharmacologic study of dye adsorption compounds. G. SPAGNOL. *Arch. sci. biol.* (Italy) **15**, 216–48(1930).—The basic dyes used were Janus green, Victoria blue 4R, Nile blue, safranine, methylene blue, and trypaflavine; the acid dyes were Congo red, trypan red, trypan blue, lithium carmine, indigo carmine, eosin, alizarin red and orange G. The proportion of the 2 dyes used was varied so that the adsorption compd. had a pos. or neg. elec. charge. Six different classes of compds. were prepd.: (1) colloidal

basic, colloidal acid dye; (2) colloidal basic, crystalloidal acid; (3) semi-colloidal basic, colloidal acid; (4) semi-colloidal basic, crystalloidal acid; (5) crystalloidal basic, colloidal acid; (6) crystalloidal basic, crystalloidal acid. The compds. were injected intravenously into rabbits, and their actions studied with particular reference to their distribution in the tissues, toxicity, and rate of scission into their resp. dyes. The compds. were distributed in the organism in an entirely different manner from that of the two-component dyes. When the acid or basic dyes were injected singly they were distributed throughout the organism but when injected in the form of the adsorption compd. they were fixed almost exclusively in the lungs, in the hemopoietic organs, or occasionally in the kidneys. The difference in their distribution depended not only on the proportion of the mixt., but also on their dispersion. Those which had well-marked colloidal characteristics showed the most difference, whereas those which had crystalloidal characteristics showed the least. The compds. were split into their component parts either in circulation or after they had been fixed in the tissues. The rate of scission was slow in those compds. in which both dyes had marked colloidal properties and was much more rapid in the compds. in which one or both dyes had crystalloidal properties. The compds. showed toxicities different from those of the components; this difference varied according to the organotropism and rate of scission. In general, when they were fixed by the lungs, their toxicities increased and at times were greater than those of either component; when they were fixed by the hemopoietic organs, their toxicities decreased and at times they were almost innocuous, especially when the rate of scission was very slow. The differences in the distribution of the dyes in the form of the compds. are explained by the phys. and chem. changes which the particles of opposite charge undergo when they are united in the compd. The variations in toxicity are explained by their organotropism and by their rapid or slow rate of scission. These results may have not only theoretical but also practical therapeutic importance. PETER MASUCCI

The results of the sclerotic injections of sodium salicylate in the treatment of hemorrhoids. RAFFAELLO PAZZAGLI. *Minerva med.* **1930**, II, 519–24.—Numerous cases of hemorrhoids in various stages were treated by means of injections of 20–40% Na salicylate. The sclerotic action of this drug has given excellent results. No counter indications have yet been established. On account of the simplicity of treatment P. recommends this form of therapy as useful and effective. PETER MASUCCI

The influence of insulin on glycogen distribution in marine fishes. R. W. ROOT, F. G. HALL AND I. E. GRAY. *J. Elisha Mitchell Sci. Soc.* **46**, 15-6(1930).—Injections of 40 units of insulin per kg. body wt. into scup fish, *Stenotomus chrysops* (Lin.), caused first a transient hyperglucemia and then a very low blood sugar level. The glycogen supply dropped in the liver and increased in the muscle for about 6 hrs. after the injections. A. L. MEHRING

Narcosis. II. The coefficient of distribution between water and lipides of various contents of double linkages. ILARIA MALANDRUCCO. *Biochim. terap. sper.* **17**, 287–94 (1930), cf. *C. A.* **20**, 2540.—The prepn. of bromural is described. Its coeff. of distribution between water and oils of different I values showed no relation to the latter. A. E. MEYER

The lipases present in blood after the action of anesthetics. MARCO PAZZI DEMURTAS. *Biochim. terap. sper.* **17**, 402–13(1930); cf. *C. A.* **24**, 2803.—The blood of dogs contains after $CHCl_3$ narcosis a quinine-resistant lipase, which is not present in normal conditions. The activity of the normal blood lipase is increased by the presence of the quinine-resistant lipase. The quantity of the latter does not depend on the quantity of $CHCl_3$ used, but on the resistance of the organism. It is of hepatic origin. Its estn. may be used as a test for the liver function after narcosis. A. E. MEYER

The anagotoxic power of mineral waters and chemotherapy. MAURICE PERRIN AND ALAIN CUÉNOT. *Presse méd.* **38**, 633–4(1930).—An emulsion of $MgCO_3$ in H_2O (1.4000) is anagotoxic to the poisoning effect of picrotoxin on mosquito larvae. Previous treatment of the larvae with $MgCO_3$ does not make them more resistant. The alkaloid and $MgCO_3$ must be in contact for a certain time. A. E. MEYER

Salicylates in the treatment of acute articular rheumatism. R. LUTEMBACHER. *Presse méd.* **38**, 634–6(1930).—Salicylates of Na, K and Ca in 5% soln. at the same ratio as in Ringer's soln. were used. The mixt. is better tolerated than the soln. of a single salt alone. A. E. MEYER

Danger of intracardiac injections of adrenaline and the value of atropine in secondary chloroform syncope. L. GARRELON AND GEORGE PASCALIS. *Presse méd.* **38**, 649–51(1930).—The heart stop observed in $CHCl_3$ poisoning after administration of adrenaline is explained by mobilization of the thyroid hormone by the adrenaline and a consequent oversensitization of the heart to the $CHCl_3$. Intracardiac injections of

0.5 mg. of atropine restore the action of the heart by making it more resistant to the poisoning effect. A. E. MEYER

Magnesium thiosulfate in conditions of shock. G. BOISSEL. *Presse méd.* **38**, 670–2(1930).—Shock of anaphylactic or other origin was successfully treated with MgS_2O_3 in 4 to 5 daily doses of 0.5 g. each or in severe cases by intramuscular injection of 10 cc. of a 10% soln. In spasmodic coryza, hay fever, etc., adrenaline was also used. In asthma and vomiting in pregnancy good results were obtained. The injections are not painful. A. E. MEYER

Mercury poisoning, its treatment with sodium thiosulfate. J. C. GONZÁLES PODESTÁ AND ROBERTO E. TORVISO. *Semana méd.* (Buenos Aires) **1931**, I, 19–24.—The $Na_2S_2O_3$ was given in intravenous injections, 10–20 cc. of a 20 or 40% soln. once or several times a day and for 5, 10 or more days. When the treatment was started several hrs. after the poisoning, 42% of the cases were saved. Unfavorable secondary effects were never observed. Anuria and azotemia give a bad prognosis. A. E. MEYER

The influence of toxic substances and of lipoids on the growth of experimental tumors. II. ELISA MORELLI. *Sperimentale* **84**, 443–55(1930); cf. *C. A.* **24**, 5379.—Lesions caused by snake poison and by tar are similar. Both produce subcutaneous hemorrhages and degeneration of the organs. The snake poison acts as an activator in the growth of tar tumors. A. E. MEYER

Experimental histological changes caused by ichthyol. ANTONIO SEVERI. *Sperimentale* **84**, 457–87(1930).—When NH_4 ichthyolate was applied directly on internal organs of animals or when given intravenously, new formations in the epithelium were observed. Conclusion: A prolonged application of ichthyol may form the stimulus to the formation of neoplasms. A. E. MEYER

Biochemical changes in the organism following the use of hypersol. O. TRAVINA. *Acta Med. Scand.* **74**, 105–28(1930).—Hypersol is an artificial serum contg. in 100 cc soln. 5 g. NaCl, 1.0 g. Na_2SO_4 crystals, 0.5 g. NaH_2PO_4, 0.4 g $NaHCO_3$ and 0.35 g. KCl This soln. is injected intramuscularly into patients with arteriosclerosis the injections being repeated 30–40 times Patients with sclerosis yield in a larger degree to this treatment than do persons suffering from uric acid diatheses. The injections of hypersol cause considerable variation in the blood cholesterol with a general tendency to an increase, this increase being apparently of hemolytic origin. The blood Ca also undergoes much variation with a marked tendency to diminution, to which effect the therapeutic value of the hypersol is ascribed. The hypersol actually induces an increased Ca elimination and thus frees the organism from excess Ca; it also increases the uric acid elimination, although this is either preceded or followed by a rise in the blood uric acid level. The best results with the hypersol treatment were obtained in cases with an initially abnormally high cholesterol content, whereas in persons with a normal cholesterol and Ca content the results were usually negative. S. MORGULIS

The influence of insulin on the physiological alimentary increase of the blood sugar. H. F. HÖST. *Acta Med. Scand.* **74**, 186–90(1930). Expts. on 6 healthy individuals demonstrate that the normal alimentary hyperglucemia is decreased by the administration of insulin. Furthermore, by the proper selection of the dose the hyperglucemic effect may be entirely destroyed. S. MORGULIS

The effect of chemically pure carbon monoxide, illuminating gas, and automobile exhaust gas on the fragility of red blood cells. MAY R. MAYERS, HELEN RIVKIN AND FRANCES KRASNOW. *J. Ind. Hyg.* **12**, 300–5(1930) —The fragility of blood cells was tested by examn. for hemolysis of a suspension of them in solns. of NaCl ranging in concn. from 0.25 to 0.6%. When normal blood was exposed to pure CO, there was no increase in the fragility of the blood cells. A sample of normal blood exposed to illuminating gas and another exposed to automobile exhaust gas both showed a tendency to increased hemolysis of the red blood cells, the former sample showing a greater hemolysis. This effect seems to be due to the presence of other toxic constituents of the gases rather than to their CO content. The hemolysis is not due to a change in H-ion concn. of the blood. N. M. NAYLOR

The effect of carbon dioxide on the nervous centers of the eye. P. P. LAZAREV *Compt. rend. acad. sci. U. R. S. S.* **1930A**, 209–10 —The sight-adaptation curve depends upon the space dimensions. It does not change for the first hr. on a subject placed in a small, soundproof, room. Then sharp fluctuation and a drop occur, thus indicating instability of the nervous centers; this is caused by accumulation of the expired CO_2 In 1–2 min. the curve rises, fluctuating, until it reaches the normal (2–4 min.). The drop of the sensitiveness varies with the amt. of CO_2 inhaled. Y. P.

A practical test for the antidiuretic action of pituitary. O. S. GIBBS. *J. Pharmacol*

40, 129–37(1930).—Pituitary ext. prevented the diuresis produced in mice by intraperitoneal injection of water. C. RIEGEL

The amide nitrogen of blood. V. A theory of ammonia metabolism. SIDNEY BLISS. *J. Pharmacol.* **40**, 171–93(1930); cf. *C. A.* **23**, 3239.—Injection of NH_3 into the femoral artery of the dog causes an increase in amide N of the blood from the femoral vein. Injection of acid into the blood results in an increase of amide N of the blood at a time when urinary NH_3 is increased, while injection of alkali results in a decrease of amide N of the blood and NH_3 of the urine. In the acidosis found in phlorhizinized dogs there is also an increase in amide N of the blood. B. believes that NH_3 neutralizes the excess acid in the blood, the NH_3 appearing in a detoxified form as amide N; it is excreted by the kidney as NH_3 again. C. RIEGEL

Mydriasis affected by sympathomimetic agents. F. F. YONKMAN. *J. Pharmacol.* 40, 195–206(1930).—The isolated iris sphincter muscle (circular fibers) from dogs and steers was placed in a bath of Ringer-Locke or Tyrode soln. Cocaine, ephedrine or adrenaline added to the bath all produce relaxation. This action is attributed to stimulation of sympathetic inhibitory fibers in the sphincter. C. RIEGEL

Resistance to morphine in experimental uremia. EATON M. MACKAY AND LOIS LOCKARD MACKAY. *J. Pharmacol.* **40**, 207–14(1930).—There was an 80–190% increase in tolerance to morphine in rats made uremic by removal of the kidneys. C. R.

The effects of barbituric acid hypnotics on basal metabolism in humans. HAMILTON H. ANDERSON, MEI-YU CHEN AND CHAUNCEY D. LEAKE. *J. Pharmacol.* **40**, 215–28(1930).—The following compds. were studied: (1) ethylisoamylbarbituric acid (amytal); (2) Na diethylbarbiturate (sodium barbital); (3) diallylbarbituric acid (dial); (4) calcium ethylisopropylbarbiturate (ipral); (5) butylethylbarbituric acid (neonal), (6) cyclohexenylethylbarbituric acid (phanodorn); (7) ethylphenylbarbituric acid (phenobarbital). All the drugs decreased tactile discrimination and increased respiratory rate. Nos. 2, 4, 5 and 6 caused decreased O_2 consumption. Nos. 1 and 7 increased O_2 consumption, while No. 3 had inconstant effects. Barbital had a more consistent effect in decreasing the pulse rate and lowering the blood pressure than the other drugs. C. RIEGEL

The action of drugs on the oxygen consumption of the frog's isolated auricle. J. CHRISTODOSS DAVID. *J. Pharmacol.* **40**, 229–34(1930).—Adrenaline caused an increase in consumption and in the rate of the heart. Strophanthin in low concn. caused a slight initial increase followed by a fall, while in high concn. it caused a decrease in O_2 consumption, and in rate of the heart. Pilocarpine was followed by a decrease in O_2 consumption and in rate. C. RIEGEL

The action of sympathetic and parasympathetic poisons on isolated veins. L. WATERMAN. *Arch. néerland. physiol.* **15**, 545–64(1930).—By means of Van Herk's photographic method W. studied the action of adrenaline pilocarpine and acetylcholine on a number of isolated veins. Adrenaline nearly always produced a vasoconstriction, while the results with the other two were somewhat uncertain. A bibliography of 98 references is appended. M. H. SOULE

Animal calorimetry. XL. The metabolism of glucose administered to the fasting dog. MARGARET DANN AND WM. H. CHAMBERS. *J. Biol. Chem.* **89**, 675–88(1930); cf. *C. A.* **24**, 1412.—On ingestion of 50 g. glucose after a fast of 19–31 days, dogs showed hyperglucemia and glucosuria, and oxidized on the first day after the fast only 4–12% of the amt. which could be oxidized under normal conditions. The non-protein respiratory quotient rose from 0.72 on the 1st day after the fast to 0.97 on the 4th. Injection of 2–6 units insulin per kg. body wt. at the time of glucose ingestion only partially increased the carbohydrate utilization. The specific dynamic action of the glucose under these conditions was apparently independent of the amt. of sugar burnt and of the blood sugar level. K. V. THIMANN

Alkaloidal aminoxides, genalkaloids; a chemical, biological and pharmacodynamical study. M. POLONOWSKI. *J. pharm. chim.* [8], **11**, 385–95, 429–44(1930).—A systematic outline is given of the work done by P. on geneserine (*C. A.* **12**, 40; **13**, 1316, 1317), genatropine, genhyoscyamine, etc. (cf. *C. A.* **18**, 231, 2709; **19**, 1426; **20**, 1114; **23**, 4271, etc.). S. WALDBOTT

Diuretic action of cacodylate of bismuth. A. BESNIER. *J. pharm. chim.* [8], **11**, 465–78(1930).—Intravenous injection of Bi cacodylate (*A*) in man is rapidly followed by diuresis, similar to the behavior of Hg [illegible] on dogs showed that with [illegible] hydrous and [illegible] secretion, although the abs. quantities of NaCl are also in- [illegible] rate of elimination of urea during 24 hrs. seems const., but tends towards [illegible] Recording graphs show that blood pressure is not modified by *A*, whether

in the general circulation or in the renal region. *A* acts essentially on the mode of filtration of the renal cell, producing in larger dose an increase of urea in the blood.
S. WALDBOTT

Pharmacodynamic study of tropanol. Relations between the secondary alcohol function and the cardiovascular action of this compound. RENÉ HAZARD. *J. pharm. chim.* [8], **11**, 513–22(1930).—A summary of previous papers, illustrated by graphs, describing the contrasts in pharmacol. actions of tropanol *vs.* pseudotropanol (*C. A.* **23**, 4271), the aminoxide derivs. of both (*C. A.* **23**, 3019; **24**, 2192), the products of demethylation of both (*Ibid*), and the action of tropanone, its oxime and semicarbazone (*C. A.* **23**, 904).
S. WALDBOTT

Acetylcholine. L. LEMATTE, G. BOINOT AND E. KAHANE. *J. pharm. chim.* [8], **10**, 220–8(1930).—A review of pharmacol. studies on acetylcholine (*A*) and derivs., notably by Hunt and Taveau (*C. A.* **1**, 582), Hunt and Renshaw (*C. A.* **19**, 1912), Gautrelet (*C. A.* **3**, 329, 1638; **4**, 782, 1761), Fourneau and Page (*C. A.* **8**, 3435) and by Villaret, Schiff-Wertheim and Justin-Besançon (*C. A.* **22**, 2991). The fact is emphasized that toxicity of *A* is small in therapeutic doses of this powerful hypotensor medicament.
S. WALDBOTT

Some past and present aspects of therapeutics. RALPH STOCKMAN. *Pharm. J.* **125**, 556–9; *Chemist and Druggist* **113**, 725–7(1930).—An historical outline of progress of medical treatment with drugs from antiquity to the present day. Among the retarding agencies have been the forced com. introduction of many useless synthetic drugs. The medical curriculum should be amended.
S. WALDBOTT

Toxic properties of tuberculoproteins and polysaccharides. FLORENCE R. SABIN, FRANKLIN R. MILLER, CHARLES A. DOAN AND BRUCE K. WISEMAN. *J. Exptl. Med.* **53**, 51–80(1931).—The temp. reaction in tuberculous and normal guinea pigs and rabbits is elicited by the tuberculoprotein and probably not at all by the polysaccharides. The polysaccharides may have some killing power under certain conditions but this is not as consistently related to dosage as in the case of the proteins. Both proteins and polysaccharides cause a change in the white blood cells when introduced by any route.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Advances in food chemistry in Czechoslovakia. FRANTIŠEK HRUŠKA. *Chem. Obzor* **5**, 224–9(1930). F. KUČERA

The microchemical determination of crude fiber. TH. VON FELLENBERG. *Mitt. Lebensm. Hyg.* **21**, 385–90(1930).—From 0.01 to 0.5 g. of the material is boiled with 10 cc. of a reagent consisting of glacial AcOH 8, HNO_3 (sp. gr. 1.4) 1 and H_2O 2 vols., filtered and washed with EtOH and Et_2O to remove fat, and the raw fiber remaining is oxidized with H_2CrO_4. Then 1 cc. 0.1 *N* $K_2Cr_2O_7$ is equiv. to 0.675 g. cellulose. F. L. S.-J.

The determination of ash in grain products. TH. VON FELLENBERG. *Mitt. Lebensm. Hyg.* **21**, 376–84(1930).—Simple ashing gives low results on materials with an acid ash, such as grain products. The addn. of a few cc. of 0.1 *N* NaOH before ashing, soln. of the weighed ash in 0.1 *N* HCl and back titration give correct results. The use of Mg acetate or $La(NO_3)_3$ gives too low results. F. L. SEYMOUR-JONES

Treating grain for the destruction of injurious insects. LAUREL DUVAL. *Food Ind.* **2**, 541–4(1930).—Ethylene oxide-solid CO_2 mixts. proved to be uniformly successful in the destruction of grain-infesting insects, when used as a fumigant. The proportions recommended are 3 lb. of ethylene oxide to 30–5 lb. of solid CO_2 per 1000 bu. of grain to be treated. Closed bins or tanks contg the grain, either closed or open top, were equally well fumigated. C. R. FELLERS

Colorimetric microreactions of glutenogenous proteins and of cellulose-like gels of wheat grains. PAUL BRUÈRE. *Compt. rend.* **191**, 792–4(1930).—By use of a soln. of 0.01 g. of *bromocresol purple*, *bromocresol green* or *phenosafranine* in 20 cc. 60% alc., a cross section of wheat grain is stained blue, purple or green at the site of glutenogenous proteides and brilliant rose or orange at the site of cellulose-like gels. Amylaceous pentosan gels and lipoids are not stained. T. H. RIDER

Influence of fertilization on the baking quality of bread cereals. M. P. NEUMANN AND O. NOLTE *Mitt. deut. landw. Ges.* **44**, 447–9(1929).—Wheat grown with complete fertilizers produces the same loaf vol. as that from unfertilized soil, but this figure decreases when unbalanced fertilizers are used. B. C. A.

The temperature effect on the solubilities of nickel, tin, copper, steel (chromium) and zinc in raw cow milk. G. N. QUAM. *Proc. Iowa Acad. Sci.* **36**, 261–2(1929); cf. *C. A.* **23**, 4277.—The soly curves for Ni, Cu and Zn show a max. within a range of 75° to 85°. Sn shows an accumulation of sturdy corrosion product above 75°, while the Cr steel (Super-ascoloy) shows no apparent change. W. G. GAESSLER

Acid-proteolytic bacteria in pasteurized milk. CONSTANTINO GORINI. *Compt. rend.* **191**, 885–6(1930).—The thermophylic, acid-proteolytic bacilli of the subtilis group are among the most harmful to the preservation of pasteurized milk The preservation of milk after pasteurization depends more upon the no. of bacteria which have resisted the heat treatment than upon the types present. T. H. RIDER

Semi-micro methods for the analysis of condensed milk. E. ELSER. *Mitt. Lebensm. Hyg.* **21**, 314–20(1930).—About 8–9 g. of condensed milk is dild. to 200 cc. with water. For total solids 20 cc. is evapd. with pumice on the steam bath, then at 100° *in vacuo* for 2 hrs. For sugars the proteins in 50 cc. are pptd. with $CuSO_4$ soln., and 20 cc of the filtrate is taken for lactose and similarly for sucrose. Total protein and albumin-globulin are detd. by the micro-Kjeldahl method. Fat is estd. in 11 cc. with the Gerber butyrometer. Cl is detd. by treating 20 cc. with concd. HNO_3 and 0.02 *N* $AgNO_3$, destroying proteins with perhydrol and titrating back with 0.02 *N* KCNS. Ash is detd. on the undiluted product, which is dried first at 70° and then at 120° *in vacuo* before ashing. The ash is dissolved in HNO_3 and used for detn. of Ca, K, Fe and P_2O_5. F. L. SEYMOUR-JONES

A simple and accurate method for the identification of added fats in milk or butter. S. CAMILLA. *Ann. chim. applicata* **20**, 527–34(1930).—See *C. A.* **24**, 4339. A. W. C.

The year's research record. A. C. DAHLBERG. *Ice Cream Trade J.* **26**, No. 10, 35–8(1930).—D. reviews the progress of research in the *dairy industry* during the previous 12 months. A. H. JOHNSON

Frozen sweet cream as an ingredient of ice cream. M. J. MACK. Mass. Agr. Expt. Sta., *Bull.* **268**, 184–93(1930).—The storage of frozen cream contg. 10% sugar is a satisfactory method of preserving surplus cream for later use in ice cream. Its quality depends upon the initial quality and the length and temp. of storage. Holding periods of less than 6 months at below —18° are recommended. The frozen creams lose a part of their whipping properties, require a longer time in the freezer to reach a definite overrun,

and show a lower max. overrun than sweet creams. Frozen cream mixes were higher in viscosity than sweet cream mixes; the fat globules are larger and more irregularly shaped. Homogenization of frozen cream did not improve its properties for ice cream making. The addn. of gelatin did not greatly improve the whipping properties of frozen cream. C. R. FELLERS

The advantages of direct expansion. N. E. OLSON. *Ice Cream Trade J.* **26**, No. 11, 60–2(1930).—The advantages of using the direct expansion system for freezing ice cream mixes are reviewed. The effects of various constituents of the mix on the properties of the whipped and frozen mix are given. A. H. JOHNSON

Packaged ice cream. K. E. WRIGHT. Mass. Agr. Expt. Sta., *Bull.* **269**, 196–206 (1930).—Lack of popularity of factory-packaged ice cream is attributed to lighter wt. and poorer texture. The light wt. may be compensated for by drawing the mix at an overrun of about 50% and also by increasing the fat content of the mix. The texture of packaged ice cream is detd. largely by the temp. of the semi-frozen product at the beginning of the hardening process, the rate of freezing either in the freezer or in the hardening room being of little significance. Texture improvement by the addn. of gelatin and by aging was the result of aging the gelatin. Because of the low overrun required in packaged goods, the overrun of easily whipped mixes must be retarded to permit drawing the mix at the proper consistency. The substitution of butter for a part of the cream was the most practical effective means of obtaining a low const. overrun. C. R. F.

The effect of high temperatures in the processing of the mix. C. D. DAHLE AND G. S. BARNHART. *Ice Cream Trade J.* **26**, No. 11, 41–3(1930); cf. *C. A.* **24**, 3063.—Processing the ice cream mix at temps. of 170° and 180°F. decreases the degree of fat clumping, reduces viscosity and freezing time and increases protein stability. The difference obtained between the temps. of 170° and 180°F. is not sufficiently great to warrant using temp. much in excess of 170°F. The greatest benefits to be had in using the high temp. result when the mix is both pasteurized and homogenized at the high temp. Lowering the temp. of the mix from 170° or 180°F. to 150°F. for homogenizing vitiates some of the advantages obtained, particularly when mixes heated to 180°F. are cooled to a temp. of 150°F. for homogenizing. The high temp. at which the mix is pasteurized has more effect on viscosity, overrun and protein stability than high homogenization temp., while high homogenization temp. has a greater effect on fat clumping than high pasteurization temp. A. H. JOHNSON

Manufacture of margarine. AAGE W. OWE. *Tek. Ukeblad* **76**, 123–7, 135–40 (1929).—An illustrated review. C. A. ROBAK

The methylene blue reductase test. Its underlying principles and a consideration of its value compared with other methods of grading milk for cheese manufacture. H. R. WHITEHEAD. *New Zealand J. Sci. Tech.* **12**, 100–7(1930).—Both the reductase test and direct microscopic count can give valuable service in improving milk supplies and consequently the quality of the resulting cheese. H. W. LEAHY

Water content of cheese. K. TEICHERT AND H. SCHLAG. *Milchwirtschaft. Forsch* **7**, 259–70(1929).—Av. values for cheese contg. 40–50 (or 20–30)% of fat are: Emmental 35, Dutch 43 (50), Tilsit 43 (52), Limburg 50 (60), Camembert 55 (62). In young cheese higher values are permissible. B. C. A.

A spectrophotometric study of the color of meats. A. A. BENEDICT. *Proc Iowa Acad. Sci.* **36**, 301–2(1929).—The rapid change in the color of meat when exposed to the air has made it very difficult to make accurate comparisons of the colors of different samples. During this investigation it was found that this change could be prevented by placing the sample of meat between glass plates immediately after cutting. A comparison of the intensity of the light diffusely reflected from various cuts of meat was made by means of a spectrophotometer in the spectral region between 500 mμ and 700 mμ. At the present time the most common method of measuring the color of meats consists in a comparison of the surface with a Munsell Color Disc. This method is considered quite satisfactory by some authorities, but its reliability is seriously questioned by others. A spectrophotometric study of the Munsell Color Disc set for different cuts of meat shows that it does not give a true indication of the spectral color of the meat W. G. GAESSLER

Occurrence and distribution of iodine in fish and fish products. GULBRAND LUNDE. *Tek. Ukeblad* **75**, 201–3, 214–6(1928).—See *C. A.* **22**, 2531. C. A. R.

Iodine content of shrimp waste. HAYWOOD PARKER, JR. AND FRANK C. VILBRANDT *J. Am. Chem. Soc.* **53**, 633–5(1931).—The wastes of shrimp fisheries showed an I content of 16.9 parts per million (dry basis); EtOH extn. indicated 44.14% org. + inorg. I. Et_2O extn. indicated 55.86% lipoid I. No thyroxine could be detected in the ext. of shrimp waste when tested by the Kendall method. C. J. WEST

Preserving fruits by freezing. I. Peaches. J. G. Woodroof. Ga. Agr. Expt. Sta., *Bull.* **163**, 3–46(1930).—Exptl. and com. methods of freezing peaches are described. When peach tissue is heated to 60–70°, more darkening occurs than at higher or lower temps. The temp. of the lye bath is more important in discoloration than the concn. of the lye. Optimum conditions for lye-peeling peaches are: Immerse for 2 min. in 10% lye (NaOH) soln. at a temp. of 60°; wash in running water and pass through a 2% citric acid soln. to neutralize the excess of alkali and to retard browning. Peach tissue freezes at 2.06° and has an osmotic pressure and f. p. similar to those of 30% sucrose soln. A 30–35% sucrose sirup added at the rate of 1 part sirup to 3 parts of peach, produces the least change in frozen or thawed peach tissue. Peaches frozen in glass containers oxidized more rapidly than those in paper or Sn containers because of the presence of air plus light. Vacuum packing greatly reduced oxidation and discoloration of the fruit. Of the substances used to prevent discoloration, 2% citric acid, 2% NaCl, 4% H_3PO_3 and 2% H_2SO_3 gave the most promising results. When air comes in contact with peach tissue, O_2 is activated through the agency of peroxidase, probably by the formation of an org. peroxide, and this in turn oxidizes the chromogen, a substance of tannoid nature; the latter, upon oxidation, gives rise to the brown pigment. **II. Figs.** J. G. Woodroof and J. E. Bailey. *Bull.* **164**, 3–11(1930).—Color, taste and texture are not affected by exposing peeled figs to the air for an hr. or more. As in freezing peaches, a 35% sugar sirup gave the best results. Fresh figs contain H_2O 70–86, sugar 10–20, acid 0.05–1.0, ash 0.4–0.5, and other org. matter 11–20%. Figs cannot be peeled by the use of lye. A very low temp. destroys the red pigment in the seed cavity. More satisfactory results were obtained at 18°, or even higher, than at lower temps. Fresh figs freeze at about —3.3°; when packed in a 35% sugar sirup the f. p. is lowered to —4.4°, and the mass remains in a solid frozen condition at —7.2°.

C. R. Fellers

California progresses in preserving citrus juice. M. A. Joslyn and George L. March. *Food Ind.* **3**, 71–3(1931).—Valencia oranges have a better sugar-to-acid ratio than navel oranges for juice purposes. To avoid inclusion of the strong oil and bitter flavor of the peel, revolving cone extractors are preferred. After screening to remove the coarser pieces of pulp, the juice is either vacuum concd. or quickly frozen, the latter method being considered the more successful. Citrus juices may be preserved by heating to 180°F. The principal cause of deterioration of frozen citrus juices is air oxidation.

C. R. Fellers

Tomato-juice manufacture. R. H. Winters. *Glass Packer* **4**, 69–71(1931).—Cold pulping is especially harmful, because it introduces O into the product and thus destroys a part of the vitamin C. Loss of vitamin C is minimized by hot pulping. Homogenization of the juice gives uniformity of texture and helps to prevent sepn. Cu, brass, bronze, galvanized and Fe equipment imparts a distinct metallic taste to tomato juice. Sterilization at 180°F. is recommended.

C. R. Fellers

Behavior of natural and artificial fruit essences towards sodium *p*-toluenesulfonchloroamide (Heyden Chloramine). A. Miermeister. *Z. Untersuch. Lebensm.* **59**, 585–94(1930).—One cc. of essence, 20 cc. of H_2O, 50 cc. of a 0.01 *N* soln. of chloramine-T reagent (*C. A.* **24**, 430) and 0.5 cc. of AcOH are kept for 4 hrs. in diffused daylight, KI and dil. H_2SO_4 are added, and the I is titrated with 0.01 *N* $Na_2S_2O_3$ soln. and starch indicator (*A*). Another 1-cc. portion is shaken with 100 cc. of H_2O and 80 cc. of Et_2O, the filtered ethereal ext. is evapd. at ordinary temp., the residue is dissolved in 2 cc. of EtOH and 20 cc. of H_2O, and the chloramine value (*B*) is found as described, the blank given by the reagent being deducted. The values *A* were detd. for 22 natural and artificial essences, and with anise, vanilla, strawberry, raspberry and mandarin, the ratios of the values for the natural to those for the artificial products were 12.3:0.9; 24.7:38.9; 6.8:29.0; 1.8:17.0; and 10.0:35.2, resp. With volatile aromatic liquids the chloramine values of five 12-cc. fractions, distd. from 1 cc. of essence and 100 cc. of H_2O, were found. With essences of natural citrus fruits, apple, mandarin and orange, artificial apple, banana, pear, apricot, anise and mandarin essences, the sum of the chloramine values of the fractions equalled the direct value *A*, but in other cases *A* was the greater, the balance being accounted for by the chloramin value of the residue after distn. The difference between the values of *A* and *B* is, therefore, taken as the chloramine value of the nonvolatile reducing substances. The results indicate that cocoa, coffee, anise, vanilla, currant, strawberry, raspberry and artificial strawberry, gooseberry, raspberry and vanilla essences contain only a small proportion of steam-volatile matter. Further directions are given for treating various beverages contg. these essences. In general, the liquids should be filtered and CO_2 removed by tossing. The reagent, $CH_3C_6H_4SO_2NNaCl$, is obtained from *p*-toluenesulfonic chloride, a by-product of the manuf. of

saccharin, and is sold as a disinfectant under the names of aktivin, mianin, chlorazene or tolamine. It is also prepd. by sulfonation of toluene, treatment of the Na salt of the sulfonic acid with PCl_5, and conversion of the resulting sulfonic chloride into sulfonamide by means of NH_3. The action of a slight excess of an alk 1.5 *N* soln. of NaOCl then produces chloramine-T, which crystallizes from the liquor. Its solns. are clear and stable for approx. 1 month, but it is decompd. by acid or alk. hydrolysis into NaCl and O_2. C. R. FELLERS

The sulfuring of apricots. A. V. LYON. *J. Council Sci. and Ind. Research* **3**, 161–6(1930).—A report of expts in Australia seeking an improvement in the method of sulfuring apricots to avoid exceeding the overseas tolerance of 14 grains of SO_2 per lb. of dried fruit. An open system with small vents and consequently slow burning gave good results with SO_2 concns. on the fruit well below the tolerance limit. A closed system caused a still lower deposition of SO_2 but produced fruit of an unsatisfactory color. Deposition was not affected by light spraying with water, spraying with a 2.5% salt soln. or by a delay of 4.5 hrs. after cutting, prior to sulfuring. J. R. NELLER

Chemical study of cranberries. F. W MORSE. Mass Agr. Expt. Sta., *Bull.* **265**, 89–102(1930).—A study of the chem. changes occurring in cranberries while ripening on the vines was made during 2 seasons. Total sugar was found to increase rapidly as the berries ripen, while total acid remained nearly unchanged. Cranberries do not acquire their max. proportion of sugar until fully ripe on the vines. Studies of cranberries in cold storage covered 2 seasons and showed that they steadily lose sugar by respiration. The total acid decreases also, but at a smaller rate. While cranberries remain sound, they contain enough acid to maintain their tart flavor 116 different lots of cranberries representing 61 distinct varieties were analyzed for total acid, total sugar and dry matter. The range in percentages of total acid was from 1.87 to 2.71 and in total sugar from 2.45 to 5.66. Thirty-five samples contained more than 4.5% sugar, 49 were between 3.5 and 4.5%, while 32 lots were under 3 5% sugar. The samples lowest in sugar were, as a rule, only partly ripe when harvested. C R. FELLERS

Increasing the color of cranberries after removal from the vines. BONNIE R FUDGE. N. J. Agr. Expts. Sta., *Bull.* 504, 3 24(1930).—Ethylene produced no effect upon the red pigment anthocyanin, but it did destroy the chlorophyll in the berries. The amt. of chlorophyll in cranberries is so small, however, that the effect of the C_2H_4 is scarcely noticeable and would not increase the market value of the berries. Chem. analyses of the sugars and acids in the berries gave no results which could warrant the com. use of C_2H_4. The effects upon respiration of the same concn. of C_2H_4 at different temps. and the effects of different concns. at the same temp. were small. C_2H_4 was most effective at the highest temp. Temp. was found under all conditions to be considerably more effective than C_2H_4 in increasing the respiration of cranberries. Bibliography. C. R. FELLERS

Pickling green olives. W. V. CRUESS. Calif. Agr. Expt. Sta., *Bull.* 498, 3–42 (1930).—The com. and exptl. pickling processes for green olives are described. The optimum NaOH concn. was 1.7–2.0% for Manzanillo, Mission, Barouni and Ascelano varieties and 1.6% for the Sevillano variety. The best depth of lye penetration was $^1/_8$–$^1/_4$ the distance to the pit for most varieties. From 5 to 6 hrs. in the lye gave sufficient penetration in most cases. Approx. 30 hrs. was required to leach out the NaOH with frequently changed water. The color formed by undue exposure during washing was permanent and greatly decreased the com. value of the product. The initial brine concn. for Manzanillo, Mission and Barouni varieties was 11%, but for Sevillano and Ascolano olives, an initial concn. of 5% gradually increased after several days to 7–8%, prevented shrinking. Eleven % NaCl brine was lowered to approx. 7$^1/_2$% after fermentation. Small quantities of vinegar, AcOH or lactic acid, as well as the addn. of active "starter," hastened the fermentation. Small quantities of dextrose aided the fermentation and resulted in increased acidity. Exclusion of air from the fermenting olives is essential because of the acid destruction by *Oidia* and film yeasts. Glass jars proved to be suitable containers for packing the finished pickled green olives. Sn cans were suitable for a few months storage only; the olives from the Sn cans turned a greenish blue color on exposure to air. Prolonged storage in Sn cans resulted in the formation of swelled cans because of H gas. The H resulted from the action of the brine on the Sn plate of the can. The oil content of Calif. green olives compares favorably with that of imported green olives, the av. being 15.98% for Manzanillo Calif. olives and 14.28% for the imported Manzanillos. C. R. FELLERS

The function of mannitol in the olive. R. NUCCORINI. *Ann. chim. applicata* 20, 535–46(1930); cf. *C. A.* 24, 3260.—The amt. of mannitol occurring in the olive tree varies from 6.11% in January to 2.19% in June and then gradually increases to 4.76%

in December. The glucose content shows a similar fluctuation, *i. e.*, from 1.46 to 0.04, then back to 0.20%; fructose and oleanolic acid show the reverse, fructose increasing from 0.46 to 1.29%, then down to 0.42, and oleanolic acid, from 0.91 to 3.71% and then down to 1.85%. N. assumes that the mannitol results from the reduction of fructose and aids in the formation of oleanolic acid, from which, in turn, the glycerides are derived. A. W. CONTIERI

Methods for determining the jellification power of pectin. A. MEHLITZ. *Konserven-Ind.* **17**, 624-6, 640-5, 654-7, 671-3(1930).—Methods of detg. the jelly strength and percentage pectin are described. The AgI method of Zeisel as described by Griebel and Weiss (*C. A.* **23**, 1680) yielded results agreeing within 3.4%. The von Fellenberg method of forming CH_3OH from pectin by the action of alkali and estn. of the CH_3OH by the colorimetric method of Denigé yielded results agreeing within 3.5% when a Duboscq colorimeter was used and 5.5% with a set of color standards. The jelly strength was detd. by the wt. of Hg necessary to break the surface of the jelly. An agreement between CH_3OH content and the jelly strength of the liquids was observed. F. P. GRIFFITHS

The inversion of sugar in the preparation of fruit preserves. S. BERLINGOZZI AND M. LIQUORI. *Ann. chim. applicata* **20**, 501-21(1930).—The conditions under which sugar contained in preserves, marmalades, etc., will crystallize out and cause "graininess" have been studied. No sugar sepd. where the proportion of invert sugar was between the limits 20 and 75%. The greatest amt. of sepn. was noted in samples contg. over 90% invert sugar. The presence of pectin greatly retarded the rate of inversion, providing the preserves were not held at temps. of over 107° for prolonged periods (60–90 min.). The percentage of inverted sugar present can be detd. roughly by the use of the polariscope. A soln. contg. 15% sugar (detd. with a refractometer) is used. The curve showing the relation of the *n* to percentage invert sugar is detd. with solns. of known compn. A. W. CONTIERI

The determination of the water content of marmalades, jams, jellies, fruit, apple and beet pulp. G. BENZ. *Konserven-Ind.* **17**, 717–9(1930).—The direct distn. of the water from a 20-g. sample with $CHCl_2{\cdot}CHCl_2$ as the refluxing liquid yielded results agreeing closely with those obtained by drying to const. wt. The method is similar to that of Bidwell and Sterling (*C. A.* **19**, 620), but the app. is modified to enable the use of a liquid heavier than water. F. P. GRIFFITHS

Cotton oils used for food. A. PERDRIGEAT. *J. pharm. chim.* [8], **12**, 307–12 (1930).—Com. French oils for some time have shown a deviation at 22° of +13° to +14° in the Jean and Amagat oleorefractometer as against +17° to +23° heretofore observed, while other consts. have remained practically the same The principal cause is a difference of origin, the oil being now imported from Egypt, formerly from Texas, U. S. A. S. WALDBOTT

Introducing the "plumit." LOWELL B. KILGORE. *Glass Packer* **2**, 65–7, 90 (1931).—A description is given of a simplified method of *measuring the gel structure* of a stiff emulsion such as mayonnaise. A graduated scale on the instrument enables readings to be taken directly as soon as the "plumit" has been dropped 1 ft. into an 8 oz. jar of the emulsion. C. R. FELLERS

Temperature control is a factor in mayonnaise manufacture. D. M. GRAY AND C. E. MAIER. *Glass Packer* **4**, 23-5, 40(1931).—Optimum consistency was obtained by emulsification at 60–70°F. In general, the lower the temp., the higher the consistency, but cold-emulsified mayonnaise lost its initial high consistency more rapidly. C. R. FELLERS

Rancidity of mayonnaise. BENJAMIN R. HARRIS AND ALBERT K. EPSTEIN. *Glass Packer* **3**, 543-6(1930).—The incorporation of an inert gas such as N or CO_2 instead of air is suggested. Four samples of mayonnaise showed variations in air content of 7.5-15.5 cc. per 100 g. The use of inert gases greatly delayed rancidity changes during storage. Egg yolk also had a protective action in preventing rancidity of the oils. The addn. of the unsaponifiable residue of corn oil to cottonseed oil greatly increased the resistance of the latter to rancidity. C. R. FELLERS

Improving cacao beans by extraction. GEORGE DEFREN. *Food Ind.* **2**, 499–502 (1930); cf. *C. A.* **24**, 5082.—A method of extn. in a continuous diffusion type of app. is described. The sol. constituents of the cacao bean are thus extd., the oil remaining in the ground residue. The cacao butter in liquor made from Accra beans, was increased by this process from 54.5 to 65%. Applications of the method are outlined. C. R. FELLERS

Analysis of chocolates. I. Determination of the constituents of pure chocolates composed solely of cacao, sugar and cacao butter. R. LECOQ. *J. pharm. chim.* [8], **12**,

101–9(1930); cf. *C. A.* **25**, 153; Bordas and Touplain, *C. A.* **3**, 811.—In 5 tables, complete analytical figures are given of pure chocolates without or with added sugar or added cacao butter, as a useful guide for the analyst. **II. Other additions to chocolates.** *Ibid* 149–59.—Further analytical data are recorded for chocolates contg. abnormal quantities of shells and germs, or added gluten flour and starch for diabetics, or added coffee, or nuts (hazel nuts, almonds, etc.), finally for milk chocolates. With the latter, detn. of casein permits calcn. of the quantity of dried milk used. With chocolates contg. hazel nuts only, or almonds only, the quantities of the nuts added may be calcd. from the I no. of the extd. fat; if mixed nuts are used, detn. of their quantity by the I no. becomes impossible. Addn. of oils or foreign butters and fats may be recognized by means of their chem. and optical consts. (Table V) detd. in the fat extd. from the chocolates. S. WALDBOTT

New processes for liquid coffee. G. L. WENDT. *Glass Packer* **3**, 581–4, 601 (1930).—Cereal taste in coffee is due to sugars and starches which are extd. from the bean and which are caramelized when the ext. is evapd. This caramel flavor is noticeable in powd. coffees but is avoided in liquid coffees when properly made. Spoilage of coffee is due to 2 factors (1) fermentation of the sugars, which is the least serious, and (2) the oxidation and rancidity of the fats which are present in the kernel of the bean and which are extd. by hot water. It is the fat in coffee which causes the stickiness of coffee grounds and the need of frequent thorough cleaning of urns and percolators. Because of the tannic acid present, only glass-lined or special inert alloy equipment can be used in the manuf. of liquid coffee. Great care is necessary in blending coffees of varying character to secure a uniform and pleasing blend. C. R. FELLERS

Preventing beverage spoilage by pre-fermentation. WILLIAM OWEN. *Food Ind.* **3**, 65–6(1931); cf. *C. A.* **24**, 171.—Pre-fermentation with yeasts, followed by filtration through Seitz filters, is recommended as a means of preserving various beverages from subsequent fermentation. It may be possible to replace chem. preservatives by pre-fermentation. Only occasional yeasts are found which do not produce unpleasant flavor changes. It is believed the yeast consumes the small amt. of N present in the beverage. C. R. FELLERS

Vanilla and vanillin during the last decade. G. MALCOLM DYSON. *Perfumery Essential Oil Record* **22**, 4–11(1931). E. H.

"Vanirom," a new substitute for vanillin in vanilla sugar, and its identification. J. J. J. DINGEMANS. *Chem. Weekblad* **27**, 694(1930).—This new substitute for vanillin is the ether of protocatechualdehyde; it is 4 times as strong as vanillin. To identify it, dissolve the residue of the ether extn. of 10 g. of the sugar in a little water, and to this add a few cc. of a satd. soln. of hydrazine sulfate; after a few min. add a few cc. of 4 *N* HCl. "Vanirom" produces a lemon-yellow ppt., while vanillin produces an orange-red one. Even in dil. soln. the color distinction is sharp. J. C. JURRJENS

Investigations on silage. I. The chemical composition of silage and its milk-producing value. H. ISACHSEN AND O. ULVESLI. *Meldinger Norges Landbruks-høiskole* **9**, Nos. 10–11, 573–625, English abstr., 625–8(1929); *Expt. Station Record* **62**, 802–3.—Of silage made from turnip tops, from sunflowers and from a mixt. of sunflowers, oats, tares and peas, the turnip-top silage had the largest protein content, the sunflower product the lowest. The nitrogenous constituents computed as crude protein had a variable compn., the NH_3 content ranging from 10 to 20%, the amino acids and peptones from 35 to 45%. The proportion of NH_3 was considered an index of the degree of decompn. of the protein content of the feed. The org. acids, especially butyric acid, were found in widely varying quantities. The greater part of the volatile org. acids disappeared in the drying of the samples. **II. A survey of the biochemical course of the process of ensilage.** S. HJORTH-HANSEN. *Ibid* 629–49, English abstr. 646–7.—The process of ensilage is considered to take place in two main stages. The first, or aerobic stage, which occurs while the plant mass contains air, is characterized by very active respiration and no formation of acids. The second, or anaerobic, stage is considered to take place in two periods, in the first of which org. acids, lactic acid especially, were found to be produced in quantities sufficient to give a H-ion concn. equiv. to p_H 3.7 to 4, the respiration in this first period of the second stage being described as "intramol." Atm. O having been entirely used up, O must be obtained from the carbohydrates, which are thereby converted into alc., acids of the formic acid series and lactic acid. The second period of the anaerobic stage is considered to begin when the acidity has reached that above stated. The enzymes are regarded as unable to work in so acid a medium, so that chem. and microbiol. processes accordingly cease. In 2 Norwegian silages examd. there were found formic, acetic, propionic, butyric and isovaleric acids, together with lactic acid. E. C. K.

Testing of Fingerling's method for siloing green forage plants. M. GERLACH. *Tierernähr.* **1**, 179–93(1930).—In Fingerling's method the chopped green material is tightly packed in the silo with the addn. of enough 0.6% HCl to cover it. The equiv. of 600 g. 100% HCl per 100 kg. green fodder is used. When the silo is full, the surface is covered with a layer of lubricating oil. Expts. were made on mustard, vetch and clovers. If the acid soln. is put in the silo first and the chopped forage added and pressed down, the acid is partly neutralized or adsorbed by the first material added, and extensive fermentation may take place in the upper layers, or throughout the greater part of the mass, with formation of acetic, lactic and butyric acids, and the mass will putrefy to such an extent as to become worthless. If the HCl soln. is sprinkled in gradually as the silo is filled, a little acetic, and sometimes lactic, fermentation occurs, but no butyric acid is formed. After several months the silage retains its structure and much of its green color, and the juice contains 0.4–0.56% free HCl and 0.2–0.4% AcOH. Almost no food value is lost. Under the same conditions it was found that 0.2% HCl would prevent butyric fermentation of green mustard but did not prevent putrefaction of serradella. The effect on the health of cows of feeding this acidified silage has not been detd.

L. E. GILSON

Comparison of roughages for finishing steers. D. S. BUCHANAN. Miss. Agr. Expt. Sta., *Bull.* **278**, 2–11(1930).—Corn, sorghum and sagrain silages and cottonseed meal were compared. Six yr. averages gave the following compn. of the feeds: cottonseed meal, ash 5.9, crude protein 42.07, fat 7.09, fiber 8.73 and N-free ext. 18.42%; corn silage, ash 1.48, crude protein 2.23, fat 0.85, fiber 7.11 and N-free ext. 15.54%; sorghum silage, ash 1.26, crude protein 1.15, fat 0.74, fiber 6.58 and N-free ext. 13.87%; sagrain silage, ash 2.17, crude protein 2.56, fat 1.05, fiber 8.06 and N-free ext. 18.96%. Exptl. feeding tests showed that 100 lb. of cottonseed hulls were equal to 189 lb. of corn silage, 272 lb. of sorghum silage or 249 lb. of sagrain silage. C. R. FELLERS

Botanical-chemical studies on the composition of hays of the Modena Province. ALDO FABBRI. *Ann. staz. sper. agraria. Modena.* [N. S.] **1**, 221–32(1930).—The botanical compn. is explained. The chem. compn. is: protein 7.64–14.70% (the max. content in the Leguminosae), cellulose 26.0–34.65 (the max. of cellulose corresponding to the min. of protein) and ash 7.22–10.20%. G. A. BRAVO

Determination of the digestibility of crude proteins by animal experiments and artificial methods. WERNER WÖHLBIER. *Tierernähr.* **1**, 426–48(1930).—The digestibility coeff. of the proteins in feeds, defined as the ratio of total protein in the feed eaten less protein in feces to total protein in the feed eaten, was detd. by feeding expts. with sheep. The values obtained were compared with the "solubility values," which was the proportion of the total protein dissolved when 2 g. of the feed was digested with 500 cc. of pepsin + HCl soln. by Stutzer's method. With feeds contg. over 60% crude protein (fish meals) the two values are practically identical. With feeds contg. 30–60% crude protein the two methods gave nearly the same values for seed meals, but the feeding method values were 5–7% lower for whale meal and dried milk. With seed meals contg. 16–29% protein the two methods agree within ±5%. With hays and vegetable feeds contg. less than 16% protein the two methods sometimes agree but more often differ so widely as to have no practical significance, the pepsin method usually giving a much higher value. L. E. GILSON

Proteins. II. Uniformity of the protein fraction extracted from orange-seed meal by salt solutions. FELIX SAUNDERS. *J. Am. Chem. Soc.* **53**, 696–700(1931).—The alkali halides in normal concn. all ext. the same amt. of N from orange-seed meal. There is no evidence for the existence of a lyotropic series in the extg. power of different salts on this meal. The protein isolated from the meal by extn. with different salts is probably the same in every case. C. J. WEST

Feeding experiments on milk cows with safflower cake. H. BÜNGER. *Tierernähr.* **1**, 408–20(1930).—The safflower, or bastard saffron, seed press cake used was similar to that described by F. Honcamp, *et al.* (*C. A.* **25**, 546). The inclusion of about 2 kg. in the daily ration of dairy cows caused a drop of 22–24% in the butter-fat content of the milk. Honcamp found a similar effect. No bad effect on the health of the cows was noticed. Cf. following abstract. L. E. GILSON

The effect of safflower cake on the quality of the milk and butter fat. A. MEETZ AND A. EICHSTÄDT. *Tierernähr.* **1**, 421–5(1930).—The chem. and phys. properties of the butter fat were not changed when safflower seed cake was fed to dairy cows as described in the preceding abstract. L. E. GILSON

Effect of [feeding with] lupine-fish meal on the quality of milk and butter fat. O. MROZEK, H. SCHLAG AND A. EICHSTÄDT. *Milchwirtschaft. Forsch.* **7**, 495–501(1929).—The proportion of large fat particles is reduced. The I value of the fat tends to rise and

the Polenske value to fall, while the sapon. and Reichert-Meissl values remain unchanged. B. C. A.

Investigation of poisoned barley from the United States. M. POPP AND J. CONTZEN. *Tierernähr.* **2**, 315–55(1930).—In the autumn of 1928 pigs fed with barley from the U. S. showed symptoms of illness not observed before. Upon examn. it was found that the grains were strongly attacked by microörganisms, among which *Gibberella saubinetti* (*Fusarium roseum*) was predominant. Pure cultures did not prove to be poisonous; normal barley could not be made poisonous by artificial means. Chem. analysis showed, in conformity with American reports, an alteration in the compn. of the grain, especially decompn. of proteins. Toxic albumins and similar toxic nitrogenous products had formed, causing the illness. Extn. with hot water removed part of the poisons, but it is not practical for large quantities. The infection of the barley took place during the growing period and especially in years following moist autumns, as the straw, often left to rot in the fields, forms, when putrifying, a favorable culture medium. German grain can be infected by the above-mentioned organism, but does not seem toxic.

SNODGRASS, KATHARINE: **Margarine as a Butter Substitute.** No. 4 of "Fats and Oils Studies." Stanford Univ.: Food Research Inst. 333 pp. Cloth, $3.

THIEME, PAUL: **Über Mutterkorn in Getreide, Mehl und Brot, seinen Nachweis und die Verhütung von Mutterkornvergiftungen.** Band 33, H. 1 of "Veroffentlichungen aus d. Gebiete d. Medizinalverwaltg." Berlin: R. Schoetz. 53 pp. M. 3.

Food. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 498,557, July 16, 1927. App. for pulverizing, dehydrating and drying potatoes is described. The dehydration of the potato mash is carried out by a rotary suction cell filter, and the final drying by heating.

Desiccated foods. CALIFORNIA FRUIT GROWERS EXCHANGE. Ger. 511,994, Dec. 16, 1927. Fruit juices and milk are mixed, homogenized and desiccated by evapn.

Preserving milling produce. DONATH'S OBSTKELTERBI UND ÄLTESTE SÄCHSISCH. KELTERBI ALKOHOLFREIER NATURMOSTE GEBR. DONATH. Ger. 513,328, Jan. 17, 1929 Maize grits, bran and other milling produce are preserved by mixing them with concd. fruit juice, without addn. of sugar, and drying in the air. Juice of apples, grapes, or cherries is suitable, preferably fresh juice that has been concd. *in vacuo* at a temp. below 50°.

Working up lupines. GES. FÜR LUPINENINDUSTRIE M. B. H. Ger. 513,075, Feb 22, 1924. An albuminous product suitable as *food* or *fodder* is prepd. from lupines, particularly *Lupinus albus*, by shelling, removing fat and the poisonous and bitter constituents in known manner, grinding and then sifting. The coarse residue from the sifting may be mixed with the non-poisonous portion of the extd. substances to produce a fodder.

Grain meal. JOHANN EHRENZELLER. Ger. 512,549, Oct. 23, 1927. Flour and cereal grain generally, is sterilized, bleached and improved for baking purposes, by the

addn. of SiO_2 gel which contains amts. of NO_x, Cl, Br, etc., due to previous treatment with these gases.

Determining moisture in substances such as flour. H. C. FREEMAN. Brit. 335,308, July 17, 1929. A weighed quantity of the material to be tested is mixed with CaC_2 in a closed vessel, and the pressure of the gas produced from the mixt. is measured. App. is described.

Flour for baking. J. DAPPER. Brit. 335,214, June 19, 1929. For improving the baking properties of flour or dough, there are added small proportions of bromate and persulfate (such as those of K) together with an acid-neutralizing agent such as $CaCO_3$ or $MgCO_3$ or both, preferably in greater proportion.

Bread, etc. FRANZ LÖW. Ger. 511,105, Jan. 3, 1928. A two-stage baking process is described in which the loaves, etc., after being baked until the dough has risen, are kept in an atm. of water vapor and (or) alc. vapor at 15–25° before the baking is completed in the second stage.

Milk, cream, cheese, etc. AKT. GES. FÜR MEDIZINISCHE PRODUKTE. Fr. 691,752, May 31, 1929. Fatty food such as milk, cream or cheese is aromatized and preserved by the addn. of diketones in the keto or enol form, such as diacetyl. Instead of the diketones, compds. which form them such as 2,3-butyleneglycol or 2,3-butanol and an oxidizing agent such as H_2O_2 may be used.

Apparatus for testing milk for solid impurities. FERDINAND REX. Ger. 511,680, Sept. 16, 1928.

Apparatus for pasteurizing milk and other liquids. HALVOR HOLTE. Norw. 45,271, June 18, 1928.

Heat-exchange apparatus suitable for the treatment of milk. BERGEDORFER EISENWERK A.-G. Brit. 335,395, Oct. 19, 1928. Structural features.

Apparatus for heating solutions such as milk, whey or buttermilk to facilitate recovery of solids. GEORGE W. GANE. U. S. 1,789,738, Jan. 20. Structural features.

Whippable "artificial cream." A. BERGSVIK, VITACREAM, LTD., and R. HELLERUD. Brit 334,863, June 8, 1929. Earth-nut oil or fat hardened to a m. p. of 32° is injected (preferably under 180–200 atm. or higher pressure through an orifice of not over 0.4 mm. diam.) into milk to which egg yolk or water-sol. proteins from egg yolk have been added (preferably at a temp. of about 60–65°), and the product is subsequently heated to a pasteurizing temp. Various details and modifications of procedure are described Cf. *C. A.* **24**, 3290.

Treating fats or fatty mixtures for the production of margarine and similar products. L. NORENBERG and V. FAURSKOV. Norw. 45,491, Aug. 20, 1928. The material is introduced between cylinders rotating with a peripheral speed of not less than 30 m per min. and preferably between 50 and 200 m per min. In this way the material present in the space before the opening between the cylinders is brought into a strong whirling motion and in a thin layer is forced through the slit opening under high pressure.

Cheese. HEINRICH JENA and JOHANNA JENA NÉE GASSNER. Ger. 511,992, Dec. 4, 1928. The ripening of cheese is accelerated by adding crumbled matured cheese to the milk prior to curdling with rennet or acid.

Cheese. HEINRICH JENA and JOHANNA JENA NÉE GASSNER. Ger. 511,993, Mar. 28, 1929. A vitamin-rich cheese is prepd. by adding fruit juices, neutralized by alkali such as $NaHCO_3$, to the cheese mass during its prepn.

Forming pressed products from alimentary pastes. GIOVANNI CRESPI. U. S. 1,790,368, Jan. 27. App. is described.

Concentrating fruit juices such as grape juice. PAUL GARRETT. U. S. 1,790,140, Jan. 27. A juice sufficiently concd. to inhibit fermentation, although contg. organisms capable of effecting fermentation within 6 days when the concentrate is dild. with 3 times its quantity of water, is prepd. by passing juice, before substantial fermentation has taken place, through a zone where it is heated to about 35–38° and concg. by the action of a vacuum while the juice is in mist form and subjecting to recycling and continuation of concg. treatment until a concentrate is obtained of a d. above 60° Balling. App. is described.

Drying fruit juices. CONSERVENFABRIK UND TROCKNUNGSWERKE HESSENLAND G. M. B. H. Ger. 513,407, Nov. 2, 1926. About 1% of pectin (calcd. as dry substance) is added to the juices before evapn. A non-deliquescent product is so obtained. The method is particularly useful with spray-drying.

Pectin. ROGER PAUL and ROBERT H. GRANDSEIGNE. Ger. 513,275, Feb. 19, 1927. A pure white pectin is prepd. by treating a pectin soln. with acetone, pressing the resulting gel, treating the pressed product again with acetone, pressing again and drying at a low temp.

Pectin. A. F. BROOKE. Brit. 334,974, May 3, 1929. See Australia 19,871 (*C. A.* **24**, 3065).

Food product from honey. OTTO A. SIPPEL. Ger. 513,329, Nov. 15, 1928. Cryst. or granulated honey is ground and aerated at atm. temp. to produce a creamy product that can easily be spread. App. is shown.

Tea-drying apparatus [with endless conveyers for continuous operation]. F. KRUPP GRUSONWERK A.-G. Brit. 335.018, Oct. 1, 1928. Structural features.

Coffee substitute. RENÉ A. B. DE CHOISY. Fr. 692,163, Jan. 14, 1930. A substitute for coffee contains coffee 50, "pois chiche" 25 and chicory 25%.

Food for animals. "LA ZOOTECNICA" DI FORTI VIVANTI, E. ROTH. Fr. 691,668, Mar 10, 1930. A food for animals is made from a mixt. of lactic, proteolitic and saccharolitic enzymes in pure and living cultures in an appropriate vehicle such as milk. A sterilized soln. of NaCl or Na phosphate may be added.

Feeding stuff from seaweed. HANS LANDMARK. Norw. 45 745, Oct. 22, 1928. The seaweed is used as a feeding substratum for fungi, particularly blastomyces, by which a partial conversion of the nutrient substances is brought about with formation of aromatic substances desirable in the product to be used as a fodder.

Feeding stuff from cellulose. ALBERT HIORTH. Norw. 43,861, Dec. 31, 1928 Materials contg. cellulose are decomposed by treating with alkali and Cl by passing them first through the alkali-producing part of an app. for electrolysis of alkali chloride, and afterward though the Cl-producing part of the same app.

Patents and secrets in chemical industry. C. P. CASPARI. *Teknisk Ukeblad* **76**, 524–5(1929).—A review. C. A. ROBAK

"Steam" distillation with alcohol vapor. E. WASER. *Mitt. Lebensm. Hyg.* **21**, 343–53(1930).—Spent H_2CrO_4 solns. from the production of synthetic camphor by oxidation of camphene to camphor contain small quantities of AcOH and other volatile acids which attack the Pb electrodes used in regenerating the H_2CrO_4 solns. In detg. these volatile acids, they are not completely removed by steam distn. but can be by distg. MeOH vapor through the soln. A small part of the MeOH is oxidized to H.COOH which is immediately esterified, while practically all of the volatile acids are esterified and distd. over. F. L. SEYMOUR-JONES

Thermotechnical measuring arrangement of a boiler house in the plan of an industrial power plant. A. GRUNWALD. *Die Wärme* **53**, 923–6(1930).—Control panels and control instruments (pyrometers, flow meters and flue-gas analyzers) are discussed in regard to their design, selection, installation and arrangement for a modern boiler plant. A. S. S.

Protecting workmen against dusts and gases. F. SCHOOPS. *Rev. hyg. méd. prév.* **52**, 909–12(1930).—The usual methods of dust removal, *i. e.*, filtration, agglomeration, aq. pptn. and elec. purification are discussed. There is great need for better protection of workers in France against dusts and noxious gases. C. R. FELLERS

What is the place of silicosis among diseases due to dust? D. GLIBERT. *Med. travail.* **1**, 51–62(1930); *U. S. Pub. Health Eng. Abstracts* **10**, IHS, 6(Dec. 6, 1930).—The course of dust-tuberculosis is traced as follows: Fine dust of SiO_2 in the lungs is slowly dissolved, whereupon it reacts with the tissues. The same result is obtained by injecting a suspension of SiO_2 intravenously. Macrophages which take up the particles of SiO_2 lose their vitality to colors. Such cells collect together and after a time the surrounding tissue becomes fibrosed. Varying with exposure to dust, this fibrosis requires

from 5 to 20 yrs. to develop. The dust cells collect to form pseudo-tubercles and at a later stage, tubercle bacilli center themselves. It is this later stage that lends seriousness to the silicosis question. Remedial measures are advocated. C. R. FELLERS

Notes on hydrogen sulfide poisoning. L. B. ALLYN. *Ind. Eng. Chem.* **23**, 234 (1931).—A case is described in which 2 persons were killed, practically instantaneously by H_2S from a discarded cylinder in a deep ravine on a hot, sultry day. I. H. O.

The Underwood typewriter and lead poisoning. LIPKOVICH. *Vestnik Sovreennoi Med.* (Moscow) July, 1929; summarized in *Bull. office intern. hyg. pub.* **22**, 166–7(1930); *U. S. Pub. Health Eng. Abstracts* **10**, IHS, 7(Dec. 6, 1930).—The cushion upon which the letter characters rest is Pb. The backstrokes of the type wear away the Pb and generate Pb dust. At Leningrad several large offices showed the presence of 0.15–0.19 mg. of Pb per cu. m. in the air at the level of the typist's mouth. Dust removed from beneath typewriters consisted of 57% Pb. When typists washed their hands in weak AcOH soln. 0.33–0.59 mg of Pb was recovered. Pb-poisoning symptoms were present to a greater extent in typists than in other workers. It is recommended that the Pb cushion on typewriters should be replaced by cork covered with velvet. C. R F.

Some notes on underground cables. E. S. SIMKINS. *Iron Steel Eng.* **8**, 32–4 (1931).—Three predominant kinds of insulating mate ials for underground cables are rubber, varnished cambric and paper. The max. allowable operating temps. for these are: rubber, $60° - E/4$; varnished cambric, $75° - E$; and paper, $90° - E$, where E = the kv. of the line. Knowledge of conditions is the key to the successful operation of cables Mech. and elec. properties of the cable must receive consideration. Protection of cables after installation is essential to their life. W. H. BOYNTON

Graphical treatment of the thermodynamics of the rectifying column (KEESOM) **2.**

Treating gases with successive liquid sprays. CARRIER ENGINEERING CO., LTD. and C. L SAINTY. Brit. 335,241, June 18, 1929 Gas is treated with successive sprays of liquid so circulated by a pump at each stage that used liquid from a preceding stage forms at least a part of the spray for the succeeding stage, so that substances which are sol. or miscible with the liquid are removed from the gas in progressive increments (the spray in any stage being of less concn. than the body of liquid in that stage). An arrangement of app. and various details of operation are described. Cf. *C. A.* **24**, 532

Separating gases by liquefaction. GES. FUR LINDE'S EISMASCHINEN A.-G. Ger. 513,032, Apr. 20, 1929. Addn to 490,878 (*C. A.* **24**, 2214).

Extraction of constituents of liquid materials. E. LANGFELDT and R. HELLERUD Brit. 334,950, June 14, 1929. For dissolving constituents of emulsions, solns. or suspensions, solvent vapors are introduced into the liquid in finely distributed condition (suitably through porous or finely perforated walls) while the liquid treated is at a temp below the b. p. of the solvent so that the latter condenses as fine drops. Various details of operation are described.

Separating solids of different densities by gravity and use of air currents. H M. CHANCE. Brit. 334,877, May 7, 1929. App. and various details of operations are described for sepg. granular materials according to density.

Separating substances from solutions or suspensions. CHEMISCHE FABRIK UND SERUMINSTITUT "BRAM" G. M. B. H. (Bruno Böttcher, inventor). Ger. 514,168, June 22, 1926. See Brit. 272,968 (*C. A.* **22**, 1815).

Separating soluble substances. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 691,642, Mar. 10, 1930. Sol. substances are sepd. by crystallizing them from a common soln. and sepg. the crystals by sorting them according to their dimensions and according to their densities. The dimensions of the particles may be regulated by a granulation, by a colloid added to the soln. or by a rapid cooling.

Determining the concentration of suspensions. ALEXANDER SLAWINSKI. Ger

513,491, Aug. 5, 1928. Sediments of the suspension are formed in a horizontal and a vertical elec. cond. cell. The difference in cond. between the contents of the cells is then detd., and also the height of the sediment in the vertical cell. From these data the concn. of the suspension is calcd. Reference is made to the detn. of the concn. of blood and the investigation of milk. App. is shown.

Method and apparatus for mixing liquids and sludges, using compressed air. A. BORSIG G. M. B. H. (Theodor Steen, inventor). Ger 513,340, Mar. 29, 1928.

Treating pulverulent or finely granular materials with liquids. THEODOR KITTL. Ger. 514,092, July 15, 1927. See Austrian 114,604 (*C. A.* **24**, 903).

Effecting exothermic reactions such as calcium chloride production. I. G. FARBENIND. A.-G (Karl Staib, inventor). Ger. 513,361, July 11, 1926. See U. S. 1,764,582 (*C. A.* **24**, 4125).

Temperature control in exothermic chemical reactions. CHARLES R. DOWNS. U. S. 1,790,369, Jan. 27. For temp. control in effecting reactions in the liquid phase by removing heat from the liquid as latent heat of vaporization of a second liquid, the latter is distributed in a suitable container such as a connected tube system throughout the body of reacting liquid and moved in the body of reacting liquid. Various details of app. are described.

Effecting photochemical reactions. I. G. FARBENIND. A.-G. (Walter Frankenburger and Christian Steigerwald, inventors). Ger. 513,461, Nov. 21, 1926. Addn. to 458,756. According to Ger. 458,756, photochem. reactions in the gas or vapor phase are effected by mixing a metal vapor with the reagents and irradiating the mixt., *e. g.*, with a Hg-vapor lamp arranged concentrically in the reaction vessel. This method is now improved by carefully purifying the reagents. Thus, a mixt. of CO and H is passed over glowing Cu, washed with NaOH soln., dried, then passed over Hg at 60°, and finally irradiated as described above, with the result that 1% of the CO is converted into aldehydes instead of only a trace if the preliminary treatment is omitted. Cf. *C. A.* **24**, 1036.

Sterilizing liquids. GEORG A. KRAUSE. Fr. 690,713, Feb. 26, 1930. Liquids are sterilized by metallic salts in extremely low concns., *e. g.*, oligodynamic, sufficient time for the sterilization to take place being allowed. After the addn. of the salt the liquid is kept out of contact with any metal less noble than the metal of the sterilizing salt. Cf. *C. A.* **24**, 3580.

Sterilizing and pasteurizing liquids such as milk or beer. HENRI STASSANO. U. S. 1,790,117, Jan. 27. The liquid is caused to flow for a few sec. in the form of a substantially uniform layer about 0.8 mm. thick through a long path between surfaces of metal, such as Cu, which are maintained at a temp. of about 70–75° throughout substantially their entire extent. App. is described.

Use of vapors of mercury, sulfur, diphenyl oxide and like high-boiling substances for heating water-tube steam boilers. BABCOCK & WILCOX, LTD. Brit. 335,153, April 13, 1929. Various details of app. and operation are described.

Making colloidal dispersions. THE ANODE RUBBER CO., LTD. Ger. 511,154, Feb. 24, 1927. See Brit. 293,071 (*C. A.* **23**, 1453).

Emulsions. DEUTSCHE HYDRIERWERKE A.-G. (Richard Hueter, inventor). Ger. 512,979, June 29, 1928. Substances insol. or only partly sol. in water are emulsified by the agency of acid esters of polybasic org. acids and high mol. alcs., or their salts. Other agents may be mixed with the esters. The examples describe the emulsification of peanut oil, etc., by esters of adipic acid and oleic or sperm oil alcs.

Preserving granular substances containing unstable substances. ALFRED MENTZEL. Fr. 692,266, Mar. 19, 1930. Granular substances contg. easily decomposable, hygroscopic or volatile substances such as salt *fertilizers* are submitted to a surface treatment whereby the unstable substance is transformed, in the surface layer of each granule, into substances of a more stable nature. Thus, if NH_4HCO_3 is the substance to be preserved, the surface of the crystals is treated with a soln. of NaCl.

Use of bismuth as a gas-tight seal in spark-plug manufacture. DOWNS SCHAAF (to Stitt Ignition Co.). U. S. 1,790,445, Jan. 27. A Bi seal is used between the electrode and insulator.

Heat insulators. RENÉ MORITZ. Fr. 692,125, June 7, 1929. Agglomerates for heat insulators are made by submitting plastic $MgCO_3$ in dry powder, treated with asbestos or not, to pressure or ramming; a small quantity of water is added.

Heat-insulating material comprising superposed layers of threads of spun glass. FIRMA OSCAR GOSSLER. Ger. 511,455, Oct. 27, 1925. See U. S. 1,771,216 (*C. A.* **24**, 4563).

Heat-insulating materials. I. G. FARBENIND. A.-G. Fr. 691,008, Mar. 4, 1930.

Alkali silicates are heated, preferably in very concd. solns., in the presence of CO_2 or gaseous mixts. contg. it. In an example a temp. of 450° is reached.

Heat insulating for "chill rooms," etc. J. GARLAND. Brit. 334,884, June 10, 1929. A mixt. of cork, MgO and $MgCl_2$ soln. is applied and, after setting, is covered with a facing layer formed from wood flour, MgO and $MgCl_2$ soln.

Insulating material for refrigerators. HERMANN KOCH. Ger. 514,177, July 4, 1928. The material consists of a vulcanized mixt. of rubber and an insulating filler, *e. g.*, cork chips.

Cable insulation. HERCULES POWDER CO. Ger. 512,803, Mar. 29, 1929. The cables are soaked in an antioxygen prepn. consisting principally of pure abietic acid or resin and free from resenes. Hydrocarbon oils may be added.

Cable insulation. ELEKTRIZITÄTS A.-G. VORM. W. LAHMEYER & CO. Ger. 512,804, Aug. 10, 1928. Concentric ceramic insulators are sepd. by poured-in layers of phenol- or cresol-CH_2O condensation products.

Insulation for electric cables. W. S. SMITH, H. J. GARNETT and J. N. DEAN. Brit. 334,840, May 9, 1929. The conductor of a cable is provided with an insulation comprising a layer of thermoplastic insulating material such as gutta-percha, rubber or a rubber-bitumen mixt., treated to develop a cellular structure (as by inclusion of air or other gas under pressure followed by release of the pressure or by addn. of a substance such as NH_4 carbonate or bicarbonate which develops gas on heating). A sponge rubber tape may be wound around the conductor. A waterproofing layer such as gutta-percha is applied over the cellular layer, and a cable thus covered is stated to have a low electrostatic capacity. Various details and modifications of manuf. are described.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

The waters of Montecatini. Problems of chemical hydrology. RAFFAELLO NASINI. *Atti III congresso naz. chim. pura applicata* **1930**, 95–117.—Analyses and *radioactivity* are shown. E. M. SYMMES

The drinking water and sewerage project for Linares, Nuevo León. ALEJANDRO SAVA. *Ingeniería* **4**, 349–57(1930).—A complete project, with maps and drawings, is given. E. M. SYMMES

The East Hamburg water supply. W. HOLTHUSEN. *Gas u. Wasserfach* **73**, 1180–3 (1930).—A discussion of plants to supply Hamburg, and the territory east of it, with water. R. W. RYAN

The Nürnberg water supply. FR. KRAUSS. *Gas u. Wasserfach* **73**, 1156–9(1930).—Measures to increase water supply are discussed. R. W. RYAN

The Spa problem and the Czechoslovak Spas. A. KOLINSKY. *Trans. 1st Intern. Congr. Sanit. Tech. and Communal Hyg.; U. S. Pub. Health Eng. Abstracts* **10**, PHA, 16(Nov. 15, 1930).—Many of the largest and richest mineral springs of Europe are in Czechoslovakia, among them the famous Karlsbad Spa. The sanitary management of these State-controlled resorts is outlined. C. R. FELLERS

The new Venturi meter installations in the Munich water system. E. HENIE. *Gas u. Wasserfach* **73**, 1225–32(1930).—Venturi meters have been installed on the various water sources and overflows, and these permit a check on water consumption at any given time. New Venturi meters have been designed which operate on much lower head than those used heretofore. R. W. RYAN

Sanitation and improvement program of the Houston water supply. J. A. SAULS AND CLYDE R. HARVILL. *Proc. 12th Texas Water-Works Short School* **1930**, 21–4; *U. S. Pub. Health Eng. Abstracts* **10**, W, 141(Dec. 20, 1930).—When floods inundated the supply wells and reservoirs, emergency sterilization with liquid Cl and chloride of lime was resorted to. Duplicate chlorination equipment was installed throughout the system to provide against interruption of service. Cl dosage was checked every hr., the dosage varying from 1.45 to 3.25 lb. per million gal. The residual Cl was checked by the *o* tolidine test and varied from 0.2 to 0.25 p. p. m. C. R. FELLERS

Water works and sewerage activities in Ontario. A. E. BERRY. *Contract Record Eng. Rev.* **44**, 1633–7(1930); cf. *C. A.* **24**, 1689, 4344, 5906.—A review of works recently completed, in progress and projected in Ontario. At the close of 1930 there were 275 municipal water works systems in operation, capable of supplying in excess of 2,000,000 people. Practically all communities of 1000 or more population are now served by public systems. Surface sources provide water for 60% of the systems,

deep wells for 26% and springs for 14%. Over 80% of the water supplied is chlorinated and 35% is filtered. There are nearly 70 municipal sewage disposal plants, 25 of which are of the activated sludge type. Sludge digestion in heated separate tanks is practiced at 7 plants and glass-covered drying beds are employed at 10 plants. The trend in sewage disposal in the United States and Europe is reviewed briefly. R. E. T.

Report of the Sanitary Water Board (Pennsylvania). THEODORE B. APPEL, Harrisburg, Pamphlet 25 pp.(1929); *U. S. Pub. Health Eng. Abstracts* **10,** S, 119–20 (Dec. 27, 1930).—The waters of the state are classified in accordance with their present and probable future use and condition. Industrial wastes and stream pollution are considered in a general way. C. R. FELLERS

Iola filtration and water-softening plant. *Proc. 8th Ann. Water-Works School* (Univ. of Kansas) **1930,** 34–6; *U. S. Pub. Health Eng. Abstracts* **10,** W, 107(Oct. 18, 1930).—The new treatment plant will include rapid sand filters and a softening plant. A lime dry-feed machine and slaker and baffled mixing chamber are described. C. R. F.

Determining factors in municipal water softening with special reference to the water supplies of Kansas. H. B. CRANE. *Proc. 8th Ann. Water-Works School* (Univ. of Kansas) **1930,** 22–33; *U. S. Pub. Health Eng. Abstracts* **10,** W, 107(Oct. 18, 1930).—Most Kansas public water supplies contain over 200 p. p. m. of total hardness. The 3 methods used for water softening are lime-soda ash, zeolites and a combination of the soda lime and zeolite methods. Typical flow sheets and costs are given for each type of softening. C. R. FELLERS

Efficiency of chlorination at Chicago. H. H. GERSTEIN. *J. Am. Water Works Assoc.* **23,** 53–62(1931).—If there is strict supervision, the Great Lakes water of widely varying pollution may be treated by chlorination alone to produce a safe drinking supply according to U. S. Treasury standards. The data cover a five-year period. As pollution increases, however, it will be necessary to add filtratio to insure a safe supply. D. K. FRENCH

Unusual uses of chlorine in a water department. R. W. KEHN. *Proc. 8th Ann. Water-Works School* (Univ. of Kansas) **2,** 86–9; *U. S. Pub. Health Eng. Abstracts* **10,** W, 121(Oct. 25, 1930).—The use of Cl for the sterilization of new water mains, distribution tanks, gravel from polluted river beds used in the construction of wells and the disinfection of ground water supplies in times of flood is discussed. In some new water mains of Kansas, pollution was found even after 3–12 months; the av. time required for new installations to clear themselves was 6½ months. C. R. FELLERS

Application of geology to deep well water supplies. H. S. MCQUEEN. *5th Ann. Rept. Missouri Water and Sewerage Conf.* **1930,** 79–81; *U. S. Pub. Health Eng. Abstracts* **10,** W, 144(Dec. 27, 1930).—The application of geology to water supply problems, such as drilling conditions, has proved very useful. An example is given of the failure of wells at Mansfield, Missouri, being directly traceable to a fault in the sandstone. By relocating the wells, 1 mile distant, water conditions were entirely normal. C. R. F.

Chlorination an integral part of purification. H. W. STREETER, *et al. Water Works and Sewerage* **77,** No. 1, 6(1930); *U. S. Pub. Health Eng. Abstracts* **10,** W, 118 (Oct. 25, 1930).—Studies by the U. S. Pub. Health Service on over 30 representative plants demonstrated that chlorination must be regarded as more than a factor of safety, *i. e.*, an integral and essential part of filter plant operation. Without chlorination most raw waters cannot be made to produce effluents conforming to the Treasury standards. For river waters of the Ohio River type, the limiting raw water *B. coli* index corresponding to a standard quality of filter effluent without chlorination is about 60 per 100 cc. For Great Lakes waters, the max. is less than 10 per cc. Prechlorination is advocated with all heavily polluted raw waters. C. R. FELLERS

Supplying (drinking) water on Great Lakes freighters. ARTHUR E. GORMAN. Wallace and Tiernan Co., *Pamphlet* 17 pp.(1929); *U. S. Pub. Health Eng. Abstracts* **10,** W, 110(Oct. 18, 1930).—Small automatic chlorinators are recommended to replace the present distn. app. in common use on these vessels. The cost of chlorination equipment compares very favorably with that of the distn. method. C. R. FELLERS

Chlorination practices and policies. A. E. GORMAN. *Proc. 12th Texas Water-Works Short School* **1930,** 94–8; *U. S. Pub. Health Eng. Abstracts* **10,** W, 105(Oct. 18, 1930).—Approx. 82% of the water supplies in N. America is chlorinated, and is used by over 60 million people. G. favors splitting the Cl dosage at 2 or more progressive points in the treatment system when a heavily polluted water is being chlorinated. To prevent aftergrowths in the distribution system, prechlorination is recommended. The control of chlorination by maintaining 0.2 p. p. m. residual Cl and making frequent tests is urged. C. R. FELLERS

Benefits derived from prechlorination. JOHN J. QUINN. Wallace and Tiernan Co., *Tech. Pub.* No. 132, 14–8; *U. S. Pub. Health Eng. Abstracts* 10, W, 123(Nov. 29, 1930).—Following filter trouble at the Knoxville, Tenn., filter plant, a month's expt. with prechlorination resulted not only in definite improvement of the filters but also of the basin and the water. Prechlorination, especially in the summer, is strongly recommended. C. R. FELLERS

Prechlorination of water supplies. WELLINGTON DONALDSON. Wallace and Tiernan Co., *Tech. Pub.* No. 132, 3–13; *U. S. Pub. Health Eng. Abstracts* 10, W, 127(Nov. 29, 1930).—Prechlorination is defined as the routine application of Cl or NaOCl at any point ahead of the filters, and in doses not requiring the subsequent use of anti-chlor or dechlorination treatment. Prechlorination should be used whenever bacterial loading has reached a point where the usual processes of coagulation, settling, filtration and effluent chlorination do not suffice at all times to give an effluent of Treasury standard quality. Advantages of prechlorination are enumerated. A bibliography is appended. C. R. FELLERS

Recent improvements in dry chemical feeders and chlorinating equipment. R. C. CLEMENT AND E. P. JOHNSON. *Proc. 5th Ann. Conference on Water Purification*, W. Va. Univ. Eng. Expt. Sta., *Tech. Bull.* No. 3, 14–5(1930); *U. S. Pub. Health Eng. Abstracts* 10, W, 116(Oct. 25, 1930).—The advantages claimed for the new dry-feed machines are elimination of arching of the chemicals, high range of feed, low power consumption compactness and cleanliness. New direct-feed chlorinators and ammoniators are recent developments. C. R. FELLERS

Simple method of testing for residual chlorine. JANE H. RIDER. *Proc. 12th Texas Water-Works Short School* 1929, 118–9; *U. S Pub. Health Eng. Abstracts* 10, W, 128(Nov. 29, 1930).—White enameled cups may be painted to serve as inexpensive and accurate standards in the *o*-tolidine test for free Cl. The method is outlined. C. R. F.

Ozone and its applications. P. OTTO. *Bull. soc. franç. élec.* 9, 129(1929); *U. S. Pub. Health Eng. Abstracts* 10, W, 141(Dec. 20, 1930).—Industrial methods of ozone production and utilization are discussed. Ozone possesses several advantages over Cl in the sterilization of drinking water. Several installations are described. C. R. FELLERS

Concerning the control and the degree of reliability of the chlorinating process of purifying drinking water, especially in relation to the use of chloramine for this purpose and the chlorine process as applied to water containing ammonia in solution. II. K HOLWERDA. *Mededeel. Dienst Volksgezondheid Nederland.-Indië* 19, Pt. 2, 325–85 (1930); cf. *C. A.* 23, 1704.—In continuation H. studies the chem. action of hypochlorites on H_2O contg. NH_3 by varying the ratio of Cl_2:NH_3 at low concns. and at p_H 6.5–6.8. It is found that when the ratio is lower than 6.3:1 (mg. per l.) only NH_2Cl with traces of $NHCl_2$ and NCl_3 remains, but with higher ratios HClO is left besides increasing amounts of NCl_3 as the ratio increases. In the course of the work methods were devised for detg. NCl_3, $NHCl_2$, NH_2Cl and HClO in mixts. of all 4. A comparison was also made of the different methods of detg. active Cl. It was found that Mn and Fe do not seriously interfere with the *o*-tolidine test but that 2 mg. NO_2 per l. of H_2O will give a color comparable to 0.5 mg. Cl per l. after a 5-min. contact with *o*-tolidine. It is recommended that both *o*-tolidine and methyl orange be used to det. the active Cl. In relation to the disinfection of H_2O contg. NH_3 H. finds that in NH_3-free H_2O of p_H 6.8 the coli count is reduced from 310 to 0 in 1 min. when 0.1 mg. Cl per l. is added, but when 0.03 mg. NH_3 per l. is present the count is only reduced from 310 to 100 in 20 min. Further expts. showed that in the presence of NH_3 there was a marked disinfectant action due to NCl_3 and $NHCl_2$. H. concludes that the *o*-tolidine test does not always give a reliable figure on which conclusions may be based in regards to the reliability of chlorination. H. W. LEAHY

Increasing the bacterial efficiency of water-purification plants. H. W. STREETER. *Proc. 8th Ann. Water-Works School* (Univ. of Kansas) 1930, 37–44; *U. S. Pub. Health Eng. Abstracts* 10, W, 107(Oct. 18, 1930).—Methods of outstanding merit as detd. by the U. S. Pub. Health Service are double-stage coagulation-sedimentation and raw water chlorination. Each of these methods has given definite evidence of effecting a substantial and consistent increase in the efficiency of rapid sand water purification plants. However, the use of improved mixing and reaction devices for coagulation, the prolongation of sedimentation periods and the addn. of larger amts. of coagulants also afford possibilities for increasing bacterial efficiency. C. R. FELLERS

Use of activated carbon in water treatment. L. V. CARPENTER. *Proc. 5th Ann. Conference on Water Purification*, W. Va. Univ. Eng. Expt. Sta., *Tech. Bull.* No. 3, 25–34(1930); *U. S. Pub. Health Eng. Abstracts* 10, W, 116(Oct. 25, 1930).—Lab. expts. showed that activated C was very effective in removing excess Cl and phenols from

water. An economical means of revivifying the activated C is at present lacking. C. R. F.

Removal of iron from water supply, Punta Gorda, Florida. CHARLES K. DODD. *J. Am. Water Works Assoc.* 23, 77–80(1931).—The supply studied carried 19.6 p. p. m. Fe and Mg and was objectionable. The treatment included moderate aeration by splashing over broken terra cotta pipe followed by upward flow filtration through a 7 ft. gravel bed. Oxidation of the Fe is started during aeration and completed during the filtration. Too much aeration does not give satisfactory removal. D. K. F.

Control of filter growths by chlorination. E. E. SMITH. *Sewage Works J.* 3, 387–93(1930).—Cl was used successfully at the Elgin, Ill., treatment plant to eliminate a severe case of pooling. The efficacy of the Cl treatment was beautifully demonstrated by chlorinating only 1 of 2 identical filters; the other filter was used as a blank. E. H.

Research into the properties of the aërobe, the non-sporulating lactose-fermenting bacteria in feces and soil in the tropics and the importance thereof for the analysis of drinking water. K. HOLWERDA. *Mededeel. Dienst Volksgezondheid Nederland.-Indië* 19, Pt 2, 289–324(1930).—H. has made a survey of the types of coli-like bacteria in native feces and soil in the Dutch East Indies The organisms were isolated from feces by planting a fresh suspension on lactose-peptone-agar (contg. 0.5% Na taurocholate). The strains from soil were obtained by preliminary enrichment in lactose broth (sometimes contg. 0.5% Na taurocholate). Of 674 strains from feces, 24 were V.-P. + and 650 V.-P −. Of the 650 V.-P. − cultures only 1 was citrate +, while 649 were citrate −. From 953 soil cultures 672 were found to be V.-P. + and 279 V.-P. −. Of the latter 151 were citrate + and 128 citrate −. Contrary to other workers, H finds a higher per cent of aerogenes in habited soils than in soils from uninhabited places H. concludes that the quant. evaluation of the number of coli-like organisms together with the identification of the organisms should be considered in the bacterial analysis of H_2O H. W. LEAHY

Comparison of the Dominick-Lauter test for B. coli in water with that of "standard methods." Final report. HAROLD W. LEAHY, J. W. FREEMAN AND CHRIS P. KATSAMPES. *Am. J. Pub. Health* 21, 11–8(1931); cf *C. A.* 25, 368.—1116 samples of water from 358 different sources have been tested according to the procedure of "Standard Methods of Water Analysis" and compared with the new methylene blue bromocresol purple medium of Dominick and Lauter (cf. *C. A* 23, 4986). The % confirmation for the total no of tubes showing gas and the total no. of samples showing gas was much higher in both cases for the new medium than for the standard lactose broth. The % confirmation for the standard lactose tubes showing gas in 24 hrs. was higher than the % confirmation for the standard lactose broth tubes showing gas in 48 hrs., but the % confirmation with the Dominick-Lauter tubes showing gas in 24 and 48 hrs. was approx. the same in each case. The % confirmation for standard lactose broth increased as the amt. of pollution in the water being treated increased, whereas the % confirmation for the new medium remained approx. the same. Of the total no. of samples showing a pos. presumptive test 100% was confirmed for the new medium whereas only 68.7% was confirmed for the standard lactose broth. The new Dominick-Lauter medium was found to be far superior to standard lactose broth for the detection of *B. coli* in water. J. A. KENNEDY

A comparison of lactose broth and lactose bile as enrichment media for the detection of pollution in farm well waters. A. G. LOCHHEAD AND D. G. HEWER. *Can. Pub. Health J.* 22, 10–15(1931).—The results of comparative tests with lactose broth and lactose bile on 482 samples of farm well waters are tabulated. The lactose broth was prepd. in accordance with "Standard Methods," and the lactose bile medium contained 10 g. peptone, 10 g. lactose and 50 g. ox bile per l., Difco dehydrated products being employed throughout. Two 10-cc. portions, two 1-cc. portions and one 0.1-cc. portion of each sample were planted in each medium, the tubes being incubated at 37°. Pos. tests were confirmed by transfers to Levine's eosin methylene blue agar, 2 isolated colonies being transferred to agar slants, preference being given to those considered to be of fecal type. Cultures thus obtained were exaind. by the usual procedures. Gram-negative, non-liquefying, lactose-fermenting rods were considered members of the coli-aerogenes group, while those which, in addn., gave a pos. methyl red test and neg. Voges-Proskauer test and showed black, usually with a more or less pronounced metallic sheen, on eosin methylene blue agar were considered *B. coli*. The results after 24 and 48 hrs. incubation of the presumptive tubes are shown separately, distinction being also made between the formation of gas occupying more or less than 10% of the inverted vial. Of 2410 tubes of each medium inoculated, 1263 and 1199 tubes of lactose broth and lactose bile, resp., showed gas formation, coli-aerogenes

group organisms being isolated from 960 of the former and 962 of the latter and fecal type *B. coli* from 649 of the former and 782 of the latter. It is of interest to note that coli-aerogenes group organisms were isolated from 61 of 229 tubes of lactose broth showing less than 10% of gas in 48 hrs., and from 29 of 172 similar lactose bile tubes, the isolations of fecal *B. coli* from these tubes being 26 and 22, resp. These results indicate that there is no advantage in employing lactose bile if the presence of coli-aerogenes group organisms is regarded as the criterion of pollution, but that lactose bile is to be preferred if fecal type *B. coli* are regarded as the index of pollution. R. E. THOMPSON

Controlling algae growths at Winslow. R. C. CLINE AND D. E. LEWIS. Ariz. State Board of Health, *Bull.* No. 54, 28–31(1930); *U. S. Pub. Health Eng. Abstracts* 10, W, 144(Dec. 27, 1930).—Following a severe storm during which the city storage reservoir received much run-off water and debris, the domestic supply developed an offensive taste and odor. Algae were found in abundance in the supply. By completely draining the reservoir, washing it down with $CuSO_4$ and adding Cl and $CuSO_4$ to the intake, all objectionable tastes and odors were eliminated. C. R. FELLERS

Experience at Charleston (W. Va.) with odor and taste control. LAWSON HAYNES *Proc. 5th Ann. Conference on Water Purification*, W. Va. Univ. Eng. Expt. Sta., *Tech. Bull.* No. 3, 35–6(1930); *U. S. Pub. Health Eng. Abstracts* 10, W, 115(Oct. 25, 1930).—Phenol tastes caused much trouble in 1929–30 in the water supply. A 2% $KMnO_4$ soln. applied at rates of 0.12–0.18 p. p. m. caused some improvement. NH_3 applied at the rate of 0.18 p. p. m. and sufficient Cl to maintain a residual of 0.2–0.3 p. p. m. at the effluent end of the sedimentation basin, both applied to the raw water entering the basin, were entirely successful in removing a serious phenol taste. C. R. FELLERS

Proper filter operation and maintenance. HARRY E. JORDAN. *J. Am. Water Works Assoc.* 23, 103–4(1931).—A decalogue for filter plant operators through which perfect results should be obtained. D. K. FRENCH

Rapid sand filtration at Durban Municipal Water Works. A. W. RUSSELL. *S African Soc. Civil Eng.* 1929, 140; *U. S. Pub. Health Eng. Abstracts* 10, W, 129(Nov. 29, 1930).—A description is given of the rapid sand filtration plant installed at the Durban Municipal Water Works to deal with 10 million gal. of water per day, drawn from the Shongweri Reservoir. $Al_2(SO_4)_3$ soln. is fed to the raw water in measuring chambers at a rate of 0.25–4 grains per gal., for turbidities of 70–200 p. p. m., with a retention period of 90 min. in the sedimentation tanks. The removal of bacteria is 91% in coagulation, 8% in filtration and 1% in chlorination. Details are given of the filter beds, media and operation. Cl is admitted to the absorption tower at a pressure of 10 lb. per sq in., a dose of 0.25–0.5 p. p. m. being sufficient to leave the necessary excess for destruction of bacteria. A typical "draw-off analysis sheet" is given which shows that turbidity was reduced from 85 to 0.7, and solids in soln. from 38 to 0.7 p.p.m. C. R. FELLERS

Ferric coagulants. L. L. HEDGEPETH. *Proc. 8th Ann. Water-Works School* (Univ of Kansas) 1930, 47–50; *U. S. Pub. Health Eng. Abstracts* 10, W, 106(Oct. 18, 1930).—The method of oxidizing copperas ($FeSO_4$) with Cl is described. The principal objection to the use of ferric coagulants is the difficulty of keeping the residual Fe to the same or a lower point as with alum treatment. The liquid and solid ferric coagulants are compared with respect to ease of application and comparative costs. C. R. FELLERS

Cold-weather troubles in the operation of the water-purification plant, Lawrence, Kansas. C. T. HOUGH. *Proc. 8th Ann. Water-Works School* (Univ. of Kansas) 1930, 55–7; *U. S. Pub. Health Eng. Abstracts* 10, W, 114(Oct. 25, 1930).—Water softening and disinfection troubles are outlined. As a result of experience in operating the plant in cold weather H. concludes: Ample retention of water should be considered in the design of settling basins for the application of Cl and also for water-softening treatment for water at low temps. Better results are obtained by double chlorination or by the application of Cl prior to the application of lime The effectiveness of Cl depends upon the contact period as well as the p_H value of the water at low tmps. C. R. F.

Home-made alum at Kansas City, Kan., filter plant. L. B. MANGUN. *Proc 12th Texas Water-Works Short School* 1930, 87–93; *U. S. Pub. Health Eng. Abstracts* 10, W, 114(Oct. 25, 1930).—The prepn., properties and relative values of com. and home-made or Hoover solid alums for use as a water coagulant are discussed. For a 5-yr. period, the cost per ton averaged $24.85. C. R. FELLERS

Residual alum in North Carolina filtered waters. J. W. KELLOGG. *J. Am. Water Works Assoc.* 23, 92–102(1931).—The conditions that result in the retention of Al are outlined. Very complete tables show the Al content of N. C. supplies. The "jar test" is suggested for control labs. and detailed instructions for this test, as well as the Hatfield hematoxylin test for Al, are given. D. K. FRENCH

Determination of ammonia in water. M. W. E. EVERS. *Verslag Mededeel. Betreffende Volksgezondheid* **1930**, 1089–103; *U. S. Pub. Health Eng. Abstracts* **10**, W, 135(Dec. 13, 1930); cf. *C.A.* **24**, 5667.—Conclusions: If water contains less than 46 p. p. m. of HCO_3^-, it is necessary to add either Na_2CO_3, $MgCO_3$ or $CaCO_3$ for quant. distn. of all saline NH_3; if more than 46 p. p. m. is present, the detn. can be performed independently of Ca, Mg or Na. This is because $CaCO_3$ is formed during the distn. and if the water contains sufficient $Ca(HCO_3)_2$ then $CaCO_3$ must be added. Care should be taken that the $CaCO_3$ is free from CaO and NH_4 compds. C. R. FELLERS

Microdetermination of potassium in waters. H. GRIFFON AND MLLE. A. BERNARD. *J. pharm. chim.* [8], **12**, 118-24(1930).—The micro method used is that of Leulier, Velluz and Griffon (*C. A.* **22**, 4405; **24**, 3549). Results of the examn. of 24 samples of French waters, each in duplicate, or more, are tabulated. They agree well for each sample, but differ from other recorded results; *e. g.*, Barral (*C. A.* **24**, 907) found 2.15 mg. K per l.; an old record gives 1.64; G. and B. found 3.77 and 3.79 mg. S. WALDBOTT

The determination of manganese in potable waters. EDWARD BARTOW AND HARRIS THOMPSON. *Proc. Iowa Acad. Sci.* **36**, 245-50(1929).—Mn was detd. in 12 samples of water by the Na bismuthate, $(NH_4)_2S_2O_8$ and K periodate methods. The total Fe, chlorides and alky. to methyl orange were also detd. on these samples but no relationship was found between the presence of Mn and varying alkalinities, chlorides and Fe. The periodate method of analysis for Mn is fully as accurate as the 2 methods in general use at the present time. The new method is much shorter than the persulfate method because all chlorides are oxidized to Cl gas which is removed in evapn.; this the pptn. of chlorides by $AgNO_3$ is unnecessary. It is shorter than the Na bismuthate method because the excess of KIO_4 is colorless and sol. in the acid soln. and need not be removed before comparing with color standards. A true permanganate color was always obtained in the periodate oxidation. The cost of KIO_4 is small because only 0.3 g. is needed for each analysis. No special app. is necessary for its use except 50 cc. Nessler tubes for color comparisons. W. G. GAESSLER

Nitrate determinations in drinking water. K. SCHERINGA *Pharm. Weekblad* **67**, 1362-3(1930).—To a sample contg. approx. 0.1 mg. NO_3 add 1 cc. of 0.5% Na salicylate and evap. to dryness on the water bath. Cool, add 1 cc. of concd. H_2SO_4 and allow to stand 10 min. Rinse with H_2O into a colorimeter glass, add 10 cc. of NaOH or NH_4OH and compare with the standard. If much chloride is present multiply by the factor $100/(100 - 10a)$, in which a represents mg. Cl. A. W. DOX

Method for taking small samples of water for gas analyses. H. FORTNER AND H. KALMUS. *Intern. Rev ges. Hydrobiol. u. Hydrog.* **22**, 346(1929); *U. S Pub. Health Eng. Abstracts* **10**, W, 130(Nov. 29, 1930).—A description and diagrams are given of an app. for the removal of small quantities of water for the quant. estn. of the O_2 content by Risch's method. The app. consists of an evacuated glass tube, about 18 mm. internal diam. and 10 cm long, sealed off to a point at 1 end and drawn out to a narrow thick-walled capillary at the other. The sample is withdrawn by breaking off the end of the capillary under water and sealing it off again when the sample has been filled. The sample is emptied into the Risch app. by breaking off the end of the capillary, inserting the latter through the hole of the glass cock of the Risch app., tilting to prevent the formation of bubbles and breaking the pointed end of the sampling tube. The method was used successfully and has the advantage that the app. occupies very little space. Bibliography. C. R. FELLERS

Report of the Committee on Painting Standpipes. ANON. *J. New Eng. Water Works Assoc.* **44**, 553-60(1930).—The prepn. of the tanks for painting and the character of painting materials and other coating permissible are outlined. D. K. FRENCH

Tin-covered copper for water-supply pipes. A. MASSINK. *Verslag. Mededeel. Betreffende Volksgezondheid* **1930**, 1069-80; *U. S. Pub. Health Eng. Abstracts* **10**, W, 135(Dec. 13, 1930).—Sn-covered Cu piping should have the following requirements: The coating must be practically without pores; the content of Cu should not exceed 0.5 mg. when the varnish is removed; the min. quantity of Sn should be 15 g. per sq. m.; the Pb content of the Sn coating must not exceed 0.5%. C. R. FELLERS

Copper and health. WM. G. SCHNEIDER. *J. New Eng. Water Works Assoc.* **44**, 485-94(1930).—Cu is taken almost daily into the system with the food and is essential to the diet. While it accumulates in the system to a certain extent, no resulting injury has been observed. It would be almost impossible to take a toxic dose because of its taste and the sickness which it would produce. The use of Cu pipe even in an acid water or the use of $CuSO_4$ in reservoir treatment should cause no anxiety. D. K. FRENCH

Sterilization of water mains. G. T. LUIPPOLD. Ariz. State Board of Health, *Bull.* No. 54, 26–8(1930); *U. S. Pub. Health Eng. Abstracts* 10, W, 144(Dec. 27, 1930).—Liquid Cl is most satisfactory and soln. feed is superior to dry gas because it gives a much better diffusion through the mains. The Cl should be applied on the suction side of the pump, and continued until a residual is obtained as indicated by the *o*-tolidine test. The sterilization efficiency should be checked by making a bacteriol. examn. for *B. coli*. $CaCl_2$ is unsatisfactory because the salt loses its strength very rapidly upon exposure to air; likewise "blowing off" the lines is unsafe. New lines should always be sterilized before use. C. R. FELLERS

Corrosion and discoloration in the water supplies of Perth, W. A. H. E. HILL. *Chem. Eng. Mining Rev.* 23, 35–40(1930).—The water supply of Perth consists of 3 types: (1) shallow catchment or hills water, (2) shallow bore or artesian water (550–800 ft. depth) and (3) deep bore water (1000–2100 ft.). Water discoloration, in certain well-defined areas, varied between a slight brown tinge and a deep coffee-brown, and was due to rust. The corrosion problem involved the deterioration of and reduction of carrying capacity of the city water mains and the accumulation in them of rust deposits and the resultant "dirty" water. The results are summarized as follows: Discoloration was due to the extremely light flocculent type of rust formed in the mains particularly by the hills catchment water. Lime treatment of the water and improved circulation in the pipes alleviate the trouble considerably. The Bayliss method of establishing a $CaCO_3$ protective coating on the insides of the water mains by a lime treatment to a p_H above the soly. curve for $CaCO_3$ failed because of the high concn. of chlorides. W H. BOYNTON

The influence of higher temperatures and salt additions on the lime-carbon dioxide equilibrium in water and the formation of the rust-resistant coating. J. TILLMANS, PAUL HIRSCH AND WILH. R. HECKMANN. *Gas u Wasserfach* 74, 1–9(1931).—Previous articles (cf. *C. A.* 23, 1973, 4987) have indicated that for a given concn. of free CO_2 in water at a given temp., there is an equiv. concn. of bound carbon dioxide (HCO_3^-) below which Ca carbonate will not be pptd., and below which no protective coating is possible. Previous data on this equil. have been available only for 17°, but this paper presents exptl. data for 40°, 60°, 80° and 100°. Free CO_2 was detd. by the method of Tillmans and Heublein (*C. A.* 6, 3301) and "bound" or bicarbonate carbon dioxide by titration against 0.1 *N* HCl, with methyl orange. These values were plotted for the above temps. as mg. CO_2 per l. Any concn. of bound carbon dioxide above the equil. curve for a given temp. will cause $CaCO_3$ to be pptd. and a rust-protective coating of Fe oxide and $CaCO_3$ to be formed, if O is present. A water may be "lime aggressive" at atm. temp., forming no protective coating, but non-aggressive at higher temps., forming a protective coating. Several practical examples are given. Low concns of NaCl have only a slight effect on the lime-CO_2 equil., but $MgCl_2$ concns. above 20 mg. MgO per l. require a much greater bicarbonate concn. (with a given free CO_2 concn.) to form a protective coating. R. W. RYAN

Diagram gives flow of water in pipes. H. L. POWELL, JR. *Eng. News-Record* 106, 78(1931).—Directions are given for the prepn. of a simple nomograph, based on the Chezy formula, for solving problems relating to the flow of water in pipes. R. E. THOMPSON

High pressure pays. M. K. DREWRY. *Power Plant Engineering* 35, 249–50 (1931).—Corrosion is considered a more serious problem than scale formation. Many methods have been worked out for the control and elimination of O, which is the agent most responsible. D. K. FRENCH

Hydraulic service characteristics of small metallic pipes. G. M. FAIR, M. C. WHIPPLE AND C. Y. HSIAO. *J. New England Water Works Assoc.* 44, 499–532(1930).—Seven varieties of pipe were used in the tests; both treated hot (140°F.) and untreated cold water was circulated. CO_2 was higher in the cold water and alky. higher in the hot The tests are described in detail. The carrying capacities of Cu and brass pipe were almost unchanged in hot as well as in cold water. Galvanized iron and steel came next, while steel and wrought iron gave very poor results because of corrosion. The superiority of galvanized iron pipes over uncoated iron pipes, however, diasppears when the protective coating is destroyed. D. K. FRENCH

Recent instances of embrittlement in steam boilers. FREDERICK G. STRAUB *Trans. A. S. M. E.* 52, No. 27, 339–45(1930).—Conditions observed in recent cases of boiler embrittlement are reported. A boiler failure at Crossett, Ark., is attributed to embrittlement resulting from the use of Na_2CO_3 treatment on a water too low in sulfate content. Emphasis is placed upon the necessity for regular inspection of leaky seams

in boilers, particularly when the boiler water does not meet the A. S. M. E. specifications. H. L. OLIN

Embrittlement in boilers. FREDERICK G. STRAUB. Univ. Ill. Eng. Expt. Sta., *Bull.* No. 216, 125 pp.(1930).—This report is a partial reprint of Bull. No. 155 and No. 177 bearing on the subject of embrittlement of boiler plate (*C. A.* 20, 2814; 22, 3125) together with new matter dealing chiefly with the solubilities of embrittling inhibitors in boiler waters, and with the concns. of solns. in capillary spaces. In general, (1) embrittlement in boiler plate is caused by the combined action of stress and chem. attack. The stresses are inherent in the construction and operation of the boiler, while the chem. attack is caused by the presence of NaOH in the boiler water. (2) Certain methods of water treatment tend to convert some safe waters into the dangerous type, *e. g.*, the treatment of waters low in sulfates with soda ash. (3) Lab. tests with special app. have shown that concns. of NaCl up to 150 g. per l. may be built up in capillaries while the strength in a large connecting tube was only 2 g. per l. (4) The presence of Na_2SO_4 retards the embrittling action and, if in proper proportions, prevents it entirely. (5) The presence of phosphates, tannates, chromates, nitrates and acetates also inhibits the embrittling action of NaOH and some of these are now in use in large power plants. (6) No steel suitable for boiler plate has been found which is resistant to the embrittling action of the caustic. H. L. OLIN

Plankton of the Lower Lake at Lunz: Its distribution in space and time during the years 1908 to 1913 (including some chemical studies). F. RUTTNER. *Intern. Rev. ges. Hydrobiol. u. Hydrog.* 23, 1. 161(1929); *U. S. Pub. Health Eng. Abstracts* 10, W, 130–1 (Nov. 29, 1930). C. R. FELLERS

The Sewage Treatment Works of Zurich, Switzerland. MAX SUTER. *Sewage Works J.* 3, 419–23(1930).—The Zurich plant is a sep. sludge digestion plant with grit chambers and sedimentation basins. The capacity of the digestion tanks is 1.24 cu. ft. per capita. E. HURWITZ

Operation of the Sewage Treatment Plant of the Bloomington and Normal Sanitary District. J. J. WOLTMAN. *Sewage Works J.* 3, 404–11(1930).—The treatment works comprise bar screens, grit chamber, pumping station, Imhoff tanks, sludge drying beds, sprinkling filters and secondary tank with Dorr clarifier. An av. of 5.5 m. g. d. are treated at an annual cost of $10.50 per m. g. E. HURWITZ

Treatment plant and intercepting sewers for Klamath Falls, Ore. CLYDE C. KENNEDY. *Western Construction News* 5, 448–52(1930); *U. S. Pub. Health Eng. Abstracts* 11, S, 7(Jan. 3, 1931).—The new plant, completed in 1929, consists of a primary sedimentation tank with provisions for continuous sludge removal and skimming, sep. sludge digestion with gas collection and heating of the digesting sludge, and chlorinating the effluent. The av. flow of sewage is 1,750,000 to 3,000,000 gal. per day contg. approx. 400–600 p. p. m. of settleable solids. With a daily *gas production* of 6600 cu. ft., the plant operates on this gas alone. C. R. FELLERS

Progress made in sewage treatment. C. K. MATTHEWS. *5th Ann. Rept. Missouri Water and Sewerage Conf.* 1930, 60–3; *U. S. Pub. Health Eng. Abstracts* 10, S, 113(Nov. 22, 1930).—Development in sewage treatment has been secured principally because of the demand for a better type effluent to prevent the pollution of water courses and in the hope of developing more economical methods of sewage treatment. Treatments are described. C. R. FELLERS

Observations on sewage farming in Europe. GEORGE A. MITCHELL. *Eng. News-Record* 106, 66–9(1931); cf. *C. A.* 24, 1690.—A discussion of sewage irrigation practice in Europe, particularly in Berlin, Paris and Moscow, and of the hygienic aspects of this method of disposal and its possibilities in the United States. R. E. THOMPSON

Purification of sewage. C. A. CAMERON. *Ind. Australian and Mining Standard* 1930, 83, 94; *U. S. Pub. Health Eng. Abstracts* 10, S, 109(Nov. 22, 1930).—Sewage purification by microörganisms is largely the result of enzyme action. The sewage of Melbourne travels a considerable distance to a sewage farm and anaerobic conversion is well advanced at the time of arrival. It is then applied to carefully graded and drained land, where the purification process is satisfactorily completed without nuisance. C. R. FELLERS

Domestic and foreign experiences of biological treatment of garbage. J. J. VAN LOGHEM. *Verslag Mededeel. Volksgezondheid.* 1930, 221–30; *U. S. Pub. Health Eng. Abstracts* 10, GR, 21–2(Oct. 11, 1930).—The cells used in Villeneuve-St. George near Paris in France and at Groningen and Utrecht in Holland are placed on posts to facilitate aeration through a hole in the bottom. Sewage is added to the garbage. The liquid dripping from the mass has a strong putrefactive odor. Gaseous odors were led to an ozone app. but this was unnecessary. The temp. of the mass reached 175°F. Com-

plete decompn. required several months, but after 20–25 days, the mass could be moved. The product is relatively inoffensive and non-infectious and can be used as a *fertilizer*. The mass is greatly reduced in vol. after decompn. is complete. C. R. FELLERS

The influence of chlorine on sewage sludge digestion. C. E. KEEFER AND HERMAN KRATZ. *Sewage Works J.* 3, 338–46(1930).—Of 7 tests made to det. the effect of chlorination of raw sewage on the digestion of the solids removed by sedimentation, two showed a decided increase over the blank in the speed of digestion; two, a slight increase; one, little difference; and two indicated a slight decrease. The chlorinated solids produced more total gas in 4 tests and more CH_4 in 5 tests. The p_H value of chlorinated solids does not drop as rapidly as that of unchlorinated solids. E. H

Symposium: Standard methods for the examination of sewage and sewage sludge. I. JACK J. HINMAN, JR. *Sewage Works J.* 3, 349–52(1930).—H. urges that complete directions for examn. of sewage be included in standard methods for the examn. of water and sewage. He recommends careful discussion of the various phases of the biochem O demand detn. before final adoption of a standard method, and the development of a standard method for detn. of settleable solids. **II.** STUART E. COBURN. *Ibid* 353.—(1) Samples for composites in the study of industrial waste should be no less than 4 liters and should be taken every 10 or 15 min. (2) A water bath with samples submerged should be included as an alternative to water seals in the detn. of biochem. O demand. (3) Mineralized distd. water should be used as dilg. water for comparison of sewages and effluents in different places. Stream water should be used in studying the effect of sewage or effluent on a stream. **III.** A. J. FISCHER. *Ibid* 353–56.—*Putrescible solids in grit samples* can be detd. as follows: 100 g. of drained sample is rotated at 120 r. p. m. in a 2-qt Dazy churn with 1100 cc. clear water. The paddles are then removed and the contents gently stirred to cause the seeds and other floating material to settle out. After 30 sec. settling, 1000 cc. of supernatant liquor is siphoned off. Four more washings are made with 1000 cc. of clear water each time. The supernatant liquors are composited, evapd. to dryness, weighed and ignited to drive off the volatile matter. The loss in wt. after ignition represents the putrescible solids in 100 g. wet grit. The wt. of the dry solids left in the jar is then detd. and the putrescible solids content calcd. to the dry basis as follows:

$$\%\ \text{putrescible solids} = \frac{(\text{Wt. of dry solids in washings} \times \%\ \text{loss on ignition})}{(\text{Wt. of dry solids in washings} + \text{wt. of dry solids left in jar})^*} \qquad \text{IV.}$$

LINN H. ENSLOW. *Ibid* 356–7.—L. discusses several accepted methods for H_2S detn. and suggests that the method of detg. residual Cl_2 in sewage and sewage effluents be standardized. **V.** W. RUDOLFS AND H. HEUKELEKIAN. *Ibid* 357–60.—A sep. section should be included in "Standard Methods" devoted to special methods for industrial waste studies. An appropriate method for the detn. of C in sewage and sewage effluents should also be included. The authors make suggestions for changes in several other phases of sewage analysis. **VI.** MORRIS M. COHEN. *Ibid* 360–3.—C. urges standardization of the method of reporting results of operation of treatment works as well as standardization of the methods of analysis. **VII.** T. C. SCHAETZLE. *Ibid* 363–5.—The drying temp. of "total residue" should be 103°. Volatile solids should be ignited at 600°. A definite preservative should be adopted for sewage samples. **VIII.** EMERY J. THERIAULT. *Ibid* 365–7.—In the detn. of dissolved O the use of permanganate is unnecessary in the absence of nitrites or iron. In the presence of much org. matter $KMnO_4$ gives lower results than the ordinary Winkler method. $KMnO_4$ gives unreliable results in sulfite waste liquors. More accurate results are obtained by use of Cl or hypochlorites, the excess oxidant being removed with I. A buffered water is recommended for use in the biochem. O demand detn. in place of tap water in cases where a suitable diln. water cannot be obtained. **IX.** CHAS. C. HOMMON. *Ibid* 367–8.—*To det. plant efficiency* it is suggested that the percent settleable solids removed be detd. as follows: It is assumed that if a settling tank is designed for a 3-hr. retention period and a representative sample of sewage is allowed to settle 3 hrs. in an Imhoff cone, the quantity of settleable solids removed in the cone would be 100% of the matter capable of being removed by sedimentation. Then the difference between the suspended solids found in the raw sewage and that found in the supernatant liquor of the Imhoff cone represents the total quantity of solids capable of being removed by the sedimentation process. The quantity of suspended solids actually in the tank effluent divided by this figure gives the percent efficiency of the tank. **X.** C. K. CALVERT. *Ibid* 368–70.—The relative stability method should be used for plant control work and the direct aeration method should be reserved for accurate check up work. The status of the dilution method for determination of biochem. O demand is still too muddled and indefinite to be regarded as a standard method. **XI.** WILLIAM

D. HATFIELD. *Ibid* 370–4.—H. recommends the inclusion in "Standard Methods" of a chapter on microörganisms common to fresh and polluted water and septic and activated sludges. This chapter should accompany numerous hand drawings. **XII.** F. W. MOHLMAN. *Ibid* 374–8.—The nitrate method for detn. of biochem. O demand should be abandoned in favor of the diln. method. Of several synthetic waters tried in an effort to find a suitable diln. water, one contg. definite quantities of $NaHCO_3$ seems the most promising. The incubation temp. and period for biochem. O demand detns. should be made standard at 20° for 5 days. **XIII.** A. M. BUSWELL AND G. E. SYMONS. *Ibid* 378–84.—The *quantity of settling solids* can be detd. by placing 1 l. of the sample in a glass tube $1^3/_4$ in. in diam. × 3 ft. long with a stopper at one end. After an hour of quiescent settling the tube is rotated gently to loosen particles adhering to the sides and allowed to stand quietly for another hour. The supernatant liquor is then siphoned down to about 50 cc. The remaining sludge and liquor are run into an evapg. dish by removing the stopper. The measuring cylinder and tube are washed down with 50 cc. of distd. water which is added to the liquor in the dish. This is then evapd. on a steam bath and the residue weighed. This wt. times 1000 gives the residue in p. p. m. A correction is made for dissolved and non-settleable solids contained in the liquid portion of the sample. The method gives more accurate results than the Gooch crucible method for this detn. The authors also describe a method for the detn. of sludge drainability. **XIV.** MAX LEVINE. *Ibid* 384.—L. describes a modified method for the detn. of nitrate in sewage. **XV.** W. S. MAHLIE. *Ibid* 385–6.—M. suggests that Sierps direct oxidation method for biochem. O demand be included in "Standard Methods" and points out need of a reliable method for the detn. of H_2S in sewage and sludges. E. HURWITZ

Studies on the function of ripe sludge. H. HEUKELEKIAN. *Sewage Works J.* **3,** 313, 337(1930); cf. *C. A.* **24,** 187.—The function of ripe sludge in sludge digestion is to regulate the p_H value of the digesting mixt. and to furnish the flora necessary to accelerate digestion. Studies by H. show the following: (1) The age of the sludge affects the rate of decompn. and gasification of the solids added to it. The sludge best suited to seeding purposes is that which has reached complete decompn., as measured by reduction in volatile matter, and has not been stored too long. (2) The optimum stage of decompn. of ripe sludge for seeding purposes occurs when the decompn. is just completed and for about a month thereafter. The presence of large quantities of raw material in the sludge and storage periods longer than a month impair its seeding value. (3) Inoculation of seeded mixts. of sludge with liquor from other digesting mixts. at different stages of decompn. resulted in acceleration of the rate of gas production when the inoculum was taken from material at the peak of gasification. (4) The neutralization of the initial acidity with lime and the addn. of NH_4 carbonate and bicarbonate and K_2HPO_4 to unseeded fresh solids regulate the p_H value of material so that the acid period of digestion is materially reduced in comparison with the untreated fresh solids or fresh solids that have been treated initially with lime. The regulation of p_H accomplished with these salts compares favorably with the maintenance of p_H by the repeated addn. of lime. These salts are of no material benefit in properly seeded and limed mixts. because the p_H is already regulated by the ripe sludge and lime E. HURWITZ

Sewage fish-pond installation in Amberg and its results up to 1929. A. WALTER. *Allgem. Fischerei-Ztg.* **1929,** 147, 162; *U. S. Pub. Health Eng. Abstracts* **10,** S, 116(Nov. 22, 1930).—The sewage clarification plant at Amberg consists of 3 Kremer tanks with adjacent sludge digestion chambers. After clarification the sewage is mixed with well water in the ratio of 1:2.3 and supplied to the fish ponds by means of a concrete channel. The ponds are 30–80 cm. deep with a total surface of 10 hectares Although carp and tench did well and gained weight it is believed that the ponds should be deeper and the diln. at least doubled. C. R. FELLERS

Making dangerous gases in sewers [conduits] harmless. A. SALMONY-KARSTEN. *Chem.-Ztg.* **54,** 858–9(1930).—Large quantities of sewer and conduit gases are removed by aspiration through manholes. An elec. car carrying the suction app. is the means employed in the removal of the dangerous gases. RUSSELL C. ERB

Production and collection of sewage gas. GEO. S. RUSSELL. *5th Ann. Rept. Missouri Water and Sewerage Conf.* **1930,** 44–5; *U. S. Pub. Health Eng. Abstracts* **10,** S, 111(Nov. 22, 1930).—See *C. A.* **24,** 5090. C. R. FELLERS

Preliminary studies on causes and remedies for mosquito breeding in sewage disposal plants. JOSEPH M. GINSBURG AND LEROY FORMAN. *Sewage Works J.* **3,** 412–8 (1930).—Most breeding places encountered in sewage treatment plants may be permanently eliminated by mech. methods. When this is not possible resort may be had

to various oils or mixts. of oils with a larvicide without seriously impairing the efficiency of the filter bed or tank on which they are spread. Oils recommended are furnace oil, light fuel oil and kerosene; the larvicides are cresylic acid and exts. of pyrethrum.
E. HURWITZ

Waste waters from sugar factories. C. MANUELLI AND S. ANSELMI. *Atti III congresso naz. chim pura applicata* 1930, 607–26.—The disposal of sugar factory effluents is very important in Italy because of the lack of deep wells for domestic use, and also particularly difficult, because the factories are massed closely together. The total water used varies from 6000 to 30,000 cu. m. per 24 hrs. per factory. Most of this water is used for washing and transporting beets, and this is relatively innocuous The diffusion, press and pulp waters are more difficult to eliminate. Previous literature is reviewed, and a brief critical description of mech., chem. and biol. disposal methods is given. The repeated use of water and the sprinkling of large areas with the waste waters are also discussed. Combinations of these methods are now used successfully in Italy, the exact method depending on local conditions. A table is appended, showing the production of beets and sugar in Italy for each yr. from 1910 to 1929.
F. W. ZERBAN

Are waste waters from a potato-starch factory injurious to fish? E. PAROW. *Z. Spiritusind.* 52, 26(1929); *U. S. Pub. Health Eng. Abstracts* 10, S, 117(Nov. 22, 1930).—The waters used for washing the potatoes in potato-starch factories contain only earthy substances; those from the starch contain sol. compds., a little starch, fibers, insol. nitrogenous compds. and sand. Other effluents contain the sol. compds. from the potato such as sugar, acids, albumin, amides and mineral substances. The insol. substances are deposited at the bottom of the stream and are harmless. The sugars and nitrogenous bodies need only be considered when the water is stagnant and ferments, in which case H_2S is formed and O_2 absorbed. The diln. is, however, very great and in winter no injurious fermentation is possible. In the running water these substances are, on the contrary, advantageous and supply food to the flora. A detailed description is given of an expt. which showed that the waste waters in question are completely inoffensive to fish.

The investigation of atmospheric pollution—report of the standing conference of coöperating bodies for the year ending March 31, 1929. NAPIER SHAW, *et al. Dept. Sci. Ind. Research 15th Rept.* 1(1930).—The object of the investigation is to obtain exact scientific information with an ultimate purpose of giving to public authorities, and to industry, assistance in dealing with the smoke problem and other questions of public health.
W. H. BOYNTON

Report of the Atmospheric Pollution Research Committee for the year ended March 31, 1929. G. C. SIMPSON, *et al. Dept. Sci. Ind. Research 15th Rept.* 2–3(1930); cf. *C. A.* 24, 4110.—A brief review of the work of the Comm. Considerable progress is noted in the measurement of S impurities in the air. SO_3 is not a normal constituent of the atm.; it appears only during fog. Progress is reported in the measurement of daylight. By the use of 2 different wave lengths fairly complete information as to quality and quantity of daylight is possible. Two methods of detg. water in fog are the Kohler and the Owen. In the former the fog-laden air is warmed until the moisture is all evapd. and the total moisture content detd. by means of a wet and dry bulb hygrometer. This method can be operated as a continuous flow method. The Owens method measures the free water alone. It is proposed to consider the construction of an app. for detg. the water content gravimetrically to provide a standard of comparison
W. H. BOYNTON

Report of the superintendent of observations. ANON. *Dept. Sci. Ind. Research 15th Rept.* 4–64(1930).—Detailed tabulated results are given on suspended matter in the atm. of London. Results with the deposit gage, with the automatic filter and showing the effect of summer and winter times on the distribution of suspended impurities

are noted. A few figures are given on the measurement of daylight. Numerous charts are included. W. H. BOYNTON

Typhoid fever epidemic in a leper hospital. LEE S. HUIZENGA. *Am. J. Pub. Health* **21**, 50–1(1931).—There were at least 60 cases of which only 3 are known to have recovered, though 5 are said to have done so. There were in total 200 inmates. Two months earlier a new group of lepers was admitted without any regular period of quarantine. Excreta of the patients has been thrown outside, and has undoubtedly found its way into the water supply contaminating both the water used for cooking and the oyster beds. J. A. KENNEDY

Term of existence of typhoid bacilli in hot-spring water and other waters. N. WATANABE. *J. Pub. Health Assoc. Japan* **6**, No. 6, 1–10(1930); *U. S. Pub. Health Eng. Abstracts* **10**, W, 135(Dec. 13, 1930).—Typhoid bacilli lived 12 days in summer and 18 days in winter, diln. 1:100, in water from the Fukushima supply. Death occurs more rapidly in polluted water than in clear water. Nakanosawa and Takayu hot springs possess disinfecting properties because typhoid bacilli perish very promptly when introduced into them. C. R. FELLERS

Bacterial analyses of swimming water. ANON. Detroit, Dept. of Health, *Swimming Pool Review*, Series 4, No. **6**, 1–2(1930); *U. S. Pub. Health Eng. Abstracts* **10**, Sw., 12(Nov. 8, 1930).—Out of 18,392 tubes contg. plantings of 0.1 cc. portions of water, in 1929, only 84 tubes showed gas formation. In 1930 only 308 out of 23,055 were pos. The use of 1 cc. plantings in tubes has been discontinued. The present standard procedure consists in making agar plates with 1.0 and 0.1 cc. portions and planting 5 ten-cc. amts. in lactose broth. Gas formers are confirmed on brilliant green bile. C. R. F.

Anti-hookworm measures in West Flores, Dutch East Indies. M. AVE. LALLEMANT. *Arch. Schiffs- u. Tropen- Hyg.* **32**, 175–8(1928); *U. S. Pub. Health Eng. Abstracts* **10**, RS, 3(June 28, 1930).—The entire population is infected with hookworm, the hemoglobin index being 58–67. The soil is heavily infested with larvae, but exposure to sun and wind greatly reduces the nos. Treatment which gives very good results consists of $2^1/_2$ cc. of CCl_4 with 15 drops of oil of chenopodium. Out of 237,000 persons treated, 6 deaths resulted. C. R. FELLERS

Dressing of Fe pyrites and heavy spar at Meggen (GLATZEL) **9**. Air filtration as applied to the steel industry (ROBINSON) **9**. Apparatus for screening and filtering materials such as sewage (U. S. pat. 1,789,425) **1**.

E. von Esmarch's Hygienisches Taschenbuch. Ein Ratgeber der praktischen Hygiene für Medizinal- und Verwaltungsbeamte, Ärzte, Techniker, Schulmänner, Architekten und Bauherren. 5th ed., revised and edited by H. Reichenbach. Berlin: J. Springer. 452 pp. Bound, M. 19.80.

POPP, CAMILLO: **Die festen städtischen Abfallstoffe, ihre Beseitgung und industrielle Verwertung.** Munich: R. Oldenbourg. 142 pp. M 7.60.

Purifying water. I. G. FARBENIND. A.-G. Fr. 692,364, Mar. 20, 1930. The last traces of silicic acid are eliminated from water with recovery of the eliminating agents by using metallic hydrates not dissolved with higher H-ion concn. values and, on the other hand, the regeneration of the hydrates is effected with lower H-ion concn. values.

Sterilizing water. CHARLES RIBBE. Fr. 690,874, July 10, 1929. Water is sterilized by distg. it at low pressure after the addn. of non-volatile antiseptics. Cheap sources of heat are used.

Apparatus for softening water by use of base-exchange materials. LYNN G. LINDSAY (to Trupar Mfg. Co.). U. S. 1,789,314, Jan. 20. Structural features.

Apparatus for softening water by treatment with base-exchange material. JOHN ASTROM (one-half to Deister Machine Co.). U. S. 1,789,961, Jan. 27. Structural features.

Apparatus for degasifying boiler-feed water, etc. KARL MORAWE. Ger. 511,005, Jan. 27, 1928.

Preventing fur in steam boilers. FILTRATORS, LTD., and VADIM SAKS. Ger. 512,698, May 19, 1926. The fur is removed or prevented from forming, by high-pressure steam and linseed-oil emulsion. Cf. *C. A.* **24**, 3584.

Preventing furring of boilers. WALTER BAUR. Ger. 512,862, Sept. 25, 1927. Furring is prevented by a mixt. contg. castor oil and metal oxide, heated to 280–300° to form a waxy mass, to which C and, optionally, metal powder, are added.

Settling tank and associated apparatus for treating sewage. C. J. HARTLEY. Brit. 334,851, April 10, 1929. Structural features.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER AND M. S. ANDERSON

Soils from Merridin, Ghooli, Salmon Gums, Wongan Hills, Chapman, Baker's Hill and Lake Brown. L. J. H. TEAKLE. *J. Roy. Soc. W. Australia* 15, 115-23(1929).—The soil types studied, with the use of a 1:2 water ext., include in the order mentioned above dark-brown clay loam, red silt loam, gray calcareous loam, bearing mallee, gray sand with a small amt. of sticky clay, red sandy loam, white sands and alk. soils. The results show: (1) a wide variation in the concn. and compn. of the soil solns.; (2) near absence of sol. phosphate; (3) deficiency of certain soils (Baker's Hill) in sol. Ca; (4) increase of phosphate in the ext. by addn. of sol. phosphate; and predominance of NaCl in the alk. soils. The latter are rich in the materials required for plant growth. Mn was found in the ext. from the Wongan Hills soil only.
W. L. HILL

Brown soils of Crimea and Caucasus. L. I. PRASOLOV. *Chem. Erde* 4, 461-74 (1930).—A review of Russian papers. B. C. A.

Physical-chemical investigations of the moors of Tekir-Ghiol and Agigea. N. T. DELEANU AND RUDOLF HOFMANN. *Bull. sect. sci. acad. roumaine* 13, 111-28(1930).—From a therapeutic standpoint the moorland soil of Tekir-Ghiol is more valuable because it is richer in sulfides and I. The content of org. and colloidal S is also higher The moorland soil of Tekir-Ghiol has a higher percentage of particles of colloidal dimensions and a higher heat capacity. JOHN R. HILL

A soil survey of the Woorinen Settlement, Swan Hill Irrigation District, Victoria. J. K. TAYLOR AND F. PENMAN. Australia Council Sci. Ind., *Research Bull.* No. 45, 3-41(1930).—In addn. to descriptions of soils and their mech. analyses, extensive chem. data are given. General chem. analyses include N, P_2O_5 and CaO. Complete analyses of sol. salts show NaCl to predominate with considerable Na_2SO_4 and $NaHCO_3$ present. Carbonates, however, are not abundant. The reaction of all the soils of this region is alk.; the p_H range is from 7.5 to 9.2. Replaceable bases are moderately high, ranging from 10 to 32 milliequivalents per 100 g. of soil. An unusual feature of the data is the high content of replaceable Mg which often exceeds the Ca content These extreme values for replaceable Mg do not appear to confer any abnormal character on the soils as regards fertility. In fact, there is no obvious connection between any of the replaceable base figures and soil fertility. M. S. ANDERSON

Chemical composition of New York soils. J. A. BIZZELL. Cornell Univ. Agr Expt. Sta., *Bull.* 513, 3-25(1930).—Chem. analyses of 101 soils and subsoils, representing 85% of the surveyed area of the State, are presented and discussed for the purpose of discovering similarities or differences. With regard to the total N, P, S, K and Mg, the types are neither distinct nor are the soils within each type closely similar. The total Ca content, however, appears to be a distinctive characteristic of a soil type Comparison of all samples on a basis of texture, without regard to soil series, shows a tendency for N, P, S, K and Mg to increase with an increase of fineness of the soil The Ca content shows no significant trend. There are pronounced differences between surface soils and subsoils. N and S are higher, and K and Mg are lower, in surface soils than in subsoils. The content of Ca varies, depending on the soil type P varies, also, with different soil types. The soils of New York are medium to high in total N, P, S, K and Mg. A majority of the most extensive soil types are low in Ca
C. R. FELLERS

Humic materials and amino nitrogen of some Indo-China soils. MARCEL RIGOTARD. *Rev. gen. sci.* 41, 580-2(1930).—Soils may be grouped according to intensity of production and accumulation of amino products. To det. the quantity of amino N in the soil 20 g. of fine dry soil is treated with 100 cc. of 1.25% HCl soln for 24 hrs. The clear liquid is decanted and the treatment is repeated with fresh acid. At the end of 48 hrs. the 2 portions of liquid are combined and filtered and to 100 cc. of the filtrate is added a little H_2SO_4 and the soln. is evapd. to a small vol. This liquid is then digested in a Kjeldahl flask with $CuSO_4$ and H_2SO_4, distd. and titrated. The N from any NH_3 is also included in the result but is so small it may be neglected. The data show that there is a relation between the rate of deterioration of the humus and its proportion in the soil. The argillo-siliceous soils have more amino N than the light soils and the

ratio (amino N/humus) × 100 of permeable soils is double that of the compact soils. Amino N varies from traces up to 0.58 part per 1000. The yellow and red soils may have the same amount of amino N but the red basaltic soils of South Indo-China will show a much larger quantity. J. R. ADAMS

Acid and alkali soils, two important soil problems in China. T. Y. TANG. *Lingnan Sci. J.* 9, 195–7(1930).—Most of the acid soils of China are found below the Yangtze River where there is a plentiful rainfall while the alkali soils occur in the northern part where there is less than 20 in. of rain annually. In some of the alkali soils there is as much as 15% of $CaCO_3$ and 1% of Na_2SO_4. The occurrence of these soils is discussed as well as the cause and correction of excess alky. or acidity. J. R. ADAMS

Character of the colloidal materials in the profiles of certain major soil groups. M. S. ANDERSON AND HORACE G. BYERS. *U. S. Dept. Agr. Tech. Bull.* 228, 24 pp. (1931) —A study is made of the influence of each of 3 major soil-making processes on the character of the colloidal materials developed in a soil profile. The processes include calcification, podsolization and lateritization. Each profile studied is representative of the dominating influence of a single one of these processes operative to the extent of developing a typical profile of its kind. Chem. analyses of each of the colloids are given, together with data for various properties which seem to characterize the materials such as heat of wetting, adsorption of H_2O vapor, moisture equivalent, content of exchangeable bases and base-exchange capacity. The calcification process leads to uniformity of colloidal material throughout the profile insofar as major constituents are concerned and property values are high. The podsolization process leads to the formation of profiles with widely differing colloidal materials in the different horizons, the SiO_2 sesquioxide ratio is high in the A horizons and markedly lower in the B horizons. Many of the property values do not correspond with those usually accompanying similar features of major chem. compn. Org. matter plays an important part in properties of these colloids. The lateritization process develops colloids of low silica sesquioxide ratio and low property values. Colloids of kaolinized material possess very low property values. H-ion concn. of electrodialyzed colloids is variable. There is, however, some tendency toward a direct relationship between H-ion concn. and silica-sesquioxide ratio. Long standing of colloids after electrodialysis brings about an increase in p_H values. M. S. ANDERSON

The nature of the base-exchange material of bentonite, soils and zeolites, as revealed by chemical investigation and x-ray analysis. W. P. KELLEY, W. H DORE AND S. M. BROWN. *Soil Science* 31, 25–55(1931); cf. *C. A.* 24, 452.—Replaceable bases of several samples of bentonite are detd. before and after grinding in a ball mill for different lengths of time. Grinding greatly increases the exchangeable bases, particularly the Mg and K. 72 hrs. grinding serves to render most of the bases exchangeable. Grinding Ca-satd. bentonite and beidellite has little effect on the exchangeable Ca but greatly increases the exchangeable Mg and K. The exchangeable bases of soil colloids are increased by grinding in a manner similar to that of bentonite. X-ray studies of these various colloidal materials shown them to be cryst., and the lines shown in the x-ray patterns are greatly dimmed by grinding. The results indicate that certain of the soil colloids are closely related to the montmorillonite-beidellite clays, others to the potash bentonites and still others to the halloysite type of clay minerals. Chem. and x-ray data clearly establish the fact that inorg. soil colloids are not zeolites The bases that occur at, or near, the surface of the crystals may be replaced by Ca or Na in the natural state, but the results of grinding expts demonstrate that Ca and Na do not extend to the centers of the crystals. The exchangeable bases of bentonites and soil colloids are but little affected by heating to 350° but the zeolites lose much of their base exchange by this treatment. In all cases base exchange is almost entirely destroyed by heating to 750°. M. S. ANDERSON

Soil efflorescences. II. H. PUCHNER. *Kolloid-Z.* 54, 87–92(1931); cf. *C. A.* 12, 734.—Qual. expts. on the form of efflorescence on the surface of dolomitic and quartz sands impregnated with dil. $NaNO_3$, Na_2SO_4, NaCl, Na_2CO_3 and Na_3PO_4 solns. are described. ARTHUR FLEISCHER

Soil sampling with a compressed air unit. H. F. BLANEY AND C. A. TAYLOR. *Soil Science* 31, 1–3(1931).—A description is given of a soil-sampling app., operated by compressed air. The time of sampling is cut to 1/8 of that required for hand work. M. S. ANDERSON

New apparatus for the mechanical analysis of soils by displacement. J. H. GOLLAN. *Bull. soc. chim. biol.* 11, 940–2(1929).—An app. is described whereby analyses of soils are effected to comply with the standard of the International Soil Conference (Washington). B. C. A.

Examination of grain sizes in clays. JOHS. GRENNESS. *Teknisk Ukeblad* **75**, 41–4, 50–2(1928).—The sample is subjected to a pre-treatment according to the standard method of Oden, cf. *C. A.* **19**, 1746. The coarser particles (above 0.045 mm.) are removed and classified by wet sifting through a set of 3 small sieves, 900-, 2500- and 16,400-mesh per sq. cm. The finer particles are classified by means of a pelometer, a vertical floater with a horizontal plate upon which sedimentation takes place, and which is provided with a long, thin, graduated, vertical stem, by which the successive sinking of the floater can be observed. C. A. ROBAK

The determination of the p_H of soils by means of the quinhydrone electrode. ROBERT FROGNIER. *Ann. Soc. Sci. Bruxelles* **50**, Ser. B., 135–44(1930).—A study has been made of the applicability of the quinhydrone electrode to p_H detns. in soils. Conclusions: (1) It is possible to det. with this electrode the p_H of soil suspensions if the suspension is concd. A soil/H_2O ratio about 1/1 is sufficient. (2) One should try to eliminate all diffusion of KCl in the suspension. (3) The purity of the quinhydrone should be checked. This is very important if a soil filtrate or centrifugate is to be examd. (4) It is better not to introduce the Pt-glass junction of the electrode into the liquid under examn.; a long Pt wire dipping in the liquid should be used. J. B. A.

Mechanism of buffer action in soils. PHILIP B. MYERS AND G. M. GILLIGAN Del. Agr. Expt. Sta., *Bull.* **166**, 3–37(1930).—The removal of dialyzable bases from the colloidal fraction of a soil by subjecting the material to electrodialysis results in the loss of its buffer capacity. H-ion concn. of the colloidal material increases as the bases are progressively removed by electrodialysis. H-ion concn. of the colloidal fraction of a soil is an index to the degree of satn. of the colloidal material with bases. H-ion concn. of different soil types is not an index to their relative buffer capacities. When acid, in excess of that required to unite with the replaceable bases of a soil colloid, is added to a dispersion of soil colloidal material the colloidal acid formed has no appreciable influence upon the ionization of the acid in excess and hence no appreciable influence upon the reaction of the resulting dispersion. Exptl. evidence indicates that the mechanism of buffer action in soils is as follows: When acid is added to a soil it reacts with the salts of colloidal acids, forming colloidal acids and crystalloidal salts. The resultant reaction of the system is only slightly altered in consequence of the weakness of the colloidal acids. When acid is added in excess of that required to react with the cations of the colloidal salts, the crystalloidal salts formed, having an ion in common with the added acid, tend to repress the ionization of the latter. The net result is a small change in the H-ion concn. of the soil dispersion. Twenty references are appended. C. R. FELLERS

Effect of calcium and phosphorus content of various soil series in Western Washington upon the calcium and phosphorus composition of oats, red clover and white clover. HENRY F. HOLTZ. Wash. Agr. Expt. Sta., *Bull.* **243**, 3–45(1930).—One hundred soil samples representing 17 series under 4 geologic soil-forming agencies and the oats and clover crops grown upon them were analyzed for Ca and P. The Olympic, a residual series, is lowest in Ca, and Whatcom, an upper glacial series, is lowest in P. The Sacramento, an alluvial series, is highest in Ca, and Spanaway, a glacial series, is highest in P. The residual and upper glacial soil series are low in both total and available P, and the residual series are also low in Ca. The lower glacial and alluvial series are the highest in Ca and P. The alluvial soils are higher in Ca than either the residual or glacial soils from which they are derived. The Ca content of oats is closely proportional to that found in the residual, upper glacial, depression deposits, and org. soils, but in the other geologic classes of soils no relation exists. The P content of oats follows the P content of the soil in each geological soil class, except in the residual and lower glacial. The P content of red clover follows the P content of the soil only in org. soils. The P content of oats follows more closely the total P content of the soil, while that of red clover follows the available P content of the soil more closely. The Ca and P content of oats grown in western Washington is lower than that of oats grown in the eastern and mid-western states, while that of red clover is about the same in the 3 areas. A large no. of samples of oats, and some of red clover, from western Washington are below the Ca and P content required for nutritional deficiency disease protection. In order to det. how the mineral content of the various hay and pasture crops may be increased, field fertilizer plots, plant house and lab. expts. are being continued. C. R. FELLERS

Influence of soil conditions, fertilizer treatments and light intensity on growth, chemical composition and enzymic activities of sugar beets. JAMES TYSON. Mich. Agr. Expt. Sta., *Tech. Bull.* **108**, 3–44(1930).—The mineral contents of both leaves and roots of beets are greatly influenced by soil conditions and fertilizer treatments,

while the intensity of light presented to the plant is more closely assocd. with the utilization of the elements than with the absorption of them. Certain soil conditions and fertilizer treatments permit the sugar beet plant to absorb mineral nutrients in amts. and ratios which are favorable to their growth. The most favorable found in these investigations was on Brookston silt loam fertilized with 100 lb. Chilean $NaNO_3$, 400 lb. superphosphate, and 100 lb. KCl per acre. The order and percentages of minerals found in the leaves were K 6.9, P 3.4, N 1.7, Ca 1.3, Mg 0.9 and the percentages in the roots were K 0.9, P 0.8, N 0.6, Mg 0.2 and Ca 0.15. Whenever the elements occurred in different order from the above the size of beets produced was smaller. The seasonal fluctuations in mineral nutrient content varied with the soil, the fertilizer treatment and the stage of growth; usually the percentages of minerals were highest in the spring, low during the summer, and, if sufficient minerals were present in the soil, high in the fall. The sugar content of the beets was increased by the use of K fertilizer on the soil which was most deficient in K but on the other soils it had little influence. The sugar content was usually highest on the plots which produced the best yield of beets on each soil. When large quantities of $NaNO_3$ were applied or when the $NaNO_3$ was applied late in the season, the sugar content was lowered. Relative sugar content was not influenced by the intensity of the light, until growth was inhibited. Catalase activity is positively correlated with vigor of growth and size of plants. Oxidase activity is greater in every case in which the growth of the plant is inhibited. Forty-six references are cited. C. R. FELLERS

Lysimeter investigations. I. Nitrogen and water relations of crops in legume and non-legume rotations. R. C. COLLISON AND J. E. MENSCHING. N. Y. Agr. Expt. Sta., *Tech. Bull.* **166**, 5–90(1930).—An unproductive soil was used in 8 tanks while a fertile Ontario loam was used in 12. In the main, 2 rotations were compared, first alfalfa 2 yrs. followed by barley and wheat, and second, timothy 2 yrs. followed by barley, then wheat. In these legume and non-legume rotations special attention was paid to N relationships. Sufficient P and K were added to all tanks to insure an excess of these elements. Practically all drainage occurred between Nov. 1 and May 1 each yr. The amt. of drainage varied with the pptn., cropping system, kind of crop, and with temp. The amt. of drainage from any tank was largely a reflection of the total amt. of dry matter removed in the crops. From an av. annual rainfall of 35.4 in. only 9 in. for the Hill soil and 7 in. for the Ontario loam were accounted for in the drainage. Moisture may have been inadequate for max. plant growth, though crop yields were large. Alfalfa in the rotation was the single factor responsible for high yields on both soils. The crop immediately following alfalfa derived the greatest benefit. Almost all N lost in the drainage water was in the form of nitrate, most of the N being lost the first and fourth years of the rotations. Nitrates were almost completely exhausted from the soil by growing crops of either timothy or alfalfa. Nine lb. of N per acre per yr. was added to the soils by natural pptn. The greatest N loss in soils was in crop removal. From 4 to 6 times as much N was removed by the crops as in the drainage water. The quantity of N lost during 12 yrs. was approx. $^1/_4$ of the total soil N present at the beginning of the expts. The content of N in crops increased materially with an increased available soil N supply. Under some conditions cereal straw had twice as much N as when grown in N-poor soils. Four-ft. deep tanks produced more dry matter than either 2- or 8-ft. tanks. Twenty-seven references are appended. C. R. FELLERS

Desert guano in Chile. W. WETZEL. *Chem. Erde* **5**, 260–75(1930).—Desert guano is found in the Toco desert, central Atacama, at spots which were formerly the breeding grounds of sea birds. It contains the mummified remains of birds and of lower organisms. The material is humus-like and is largely sol. in NH_3 soln.; sandy impurities and salts (P_2O_5 3.89%) are present in smaller quantity. The org. (mummy) substance contains C 41.2, H 5.2, O 37.1, N 16.2%, and the chitinous material, insol. in NH_3 soln., contains C 38.4, H 5.7, O 37.9, N 20.1%. B. C. A.

Liming experiments [on soils]. O. NOLTE AND M. RAUTERBERG. *Mitt. deut.-Ges.* 1929, 565.—The importance of liming in conjunction with the increasing use of artificial fertilizers is emphasized. Field trials show that the effect of lime on crop yields can be closely correlated with the soil's content of exchange acidity and $CaCO_3$ but not with the total Ca content and H-ion concn. B. C. A.

Alterations of soil structure by natural and artificial fertilizers. G. HAGER. *Mitt. deut. landw. Ges.* **1929**, Stück 1, 143.—Humus and basic Ca compds. are indispensable for the maintenance of good soil structure. $CaCl_2$, $Ca(NO_3)_2$ and gypsum are less effective, since they are not intimately assocd. with the soil particles and cannot remove soil acids. Basic Mg compds. are similarly favorable to soil structure but to a smaller extent

than the corresponding Ca salts. On account of the formation of $(NH_4)_2CO_3$ from the urea contained in liquid manure, the latter tends to incrust and "puddle" heavy soils. Superphosphate has no effect on soil structure, and no unfavorable effects result from the use of $(NH_4)_2SO_4$ or combined fertilizers contg. NH_4 salts. The unbalanced use of potash salts and of $NaNO_3$ is injurious to soil structure, but the ill effects may be avoided by the judicious combination with other fertilizers. B. C. A.

Thermophosphates from Khibinsk apatite-nepheline rocks. S. N. Rozanov. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 105–9(1930).—Two samples of the phosphates, one contg. 11.55% of P_2O_5, the other contg. 31.52% P_2O_5, were treated by various thermal fusion methods. By the Wiborg method (fusion with Na_2CO_3) at a temp. of 1000° for 1 hr. the first sample of phosphate (low in P_2O_5) became citrate sol. (100%) when treated with 25% Na_2CO_3, while the second sample required 50% Na_2CO_3 to obtain similar results. Fusions by the Volter method at 1000° with various proportions of Na_2CO_3, $CaCO_3$, SiO_2, and coal did not give as good results as the Wiborg method. Sample one gave higher yields of citrate-sol. P. There was very little increase in sol. P when the temp. was increased from 1000° to 1250°. Fusions were also made with carnalite (20 min. at 700°) according to the Easthard method and the highest yield obtained was 71% with the low-grade phosphate. For the Rhenania process 100 parts of the phosphate was mixed with 25 parts $CaCO_3$ + 25 parts of Na_2SiO_3 or 10 parts $CaCO_3$ + 50 parts Na_2SiO_3 and heated at 1200°. The results were favorable only with the higher amts. of Na_2SiO_3. Mixts. of the rock with nepheline and KCl at 1000° gave no results. Of all the processes tested the Na_2CO_3 fusion proved to be the best. J. S. Joffe

Commercial fertilizers, 1930. James M. Bartlett. Maine Agr. Expt. Sta., *Official Inspection Bull.* **137**, 38–64(1930).—Inspection analyses are given. *Colloidal phosphate*, a new rock phosphate flour from Fla., showed 20.5% P_2O_5 and no K_2O or N. Field expts. with this fertilizer were inconclusive. C. R. Fellers

"Nitrophoska" as a fertilizer. O. Nolte and M Rauterberg. *Mitt. deut. landw.-Ges.* **44**, 62(1929).—Fertilizer trials in 1928 confirm the satisfactory nature of "Nitrophoska" as a complete fertilizer. Soils must be well limed to insure regular and certain results from this fertilizer. B. C. A.

Flax and mineral fertilizers. A S. Mitrofanov. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 86–93(1930).—M. reports fertilizer expts. conducted on the non-chernozem soils with flax in various rotations. The calcns. were made with the Mitscherlich formula. The following results were obtained: Flax responds best to a complete fertilizer. N is more effective in combination with P. Heavy applications of N and P have an injurious effect on the yield of fiber and its quality. This is especially true with N. Potash applications somewhat decrease this injury. There were no sharp differences from the various sources of N or K. A light application of a complete fertilizer on the crops succeeding clover and preceding flax is very favorable. At a p_H 4.5 obtained with a salt ext. high applications of lime had no effect. J. S. J.

Summary of the results obtained from field experiments with fertilizers. XIII. Fertilization of flax. L. L. Balashev. *Trans. Sci Inst. Fertilizers* (Moscow) No. 69, 5–46(1930); cf. *C. A.* **23**, 231; **24**, 1925, 5098.—The response of flax to fertilizers differs from the grains inasmuch as it has been shown that flax takes from the soil only 1/3 of its nutrient requirements in the first 45 days of its vegetative period and continues to absorb nutrients to the end of its vegetative life. Flax is very sensitive to an increase in the concn. of the soil soln. and naturally is sensitive to mineral fertilization. High applications of lime adversely affect the seeds. NaCl is favorable for the fiber quality. Phosphates act beneficially on heavy soils. N and especially K are beneficial for light soils. Thomas slag is more efficient than acid phosphate. The quality of fiber is improved by P applications. **XIV. Influence of fertilizers in the Government of Kiev.** S. T. Antoshin. *Ibid* No. 71, 17–166.—A. reviews the fertilizer expts. conducted in the region with rye, potatoes, oats, lupines, sugar beets and wheat on some chernozem and degraded chernozem soils. P was found to be lacking in all soils, followed by N; K showed beneficial effects on meadows and light soils. J. S. J.

The response of various plants to a complete fertilizer. F. A. Shwartz. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 102–4(1930).—A complete fertilizer, $(NH_4)_2SO_4$, superphosphate, and 40% potash salts, was applied (40 kg. each of N, P_2O_5 and K_2O) to spring wheat, barley, oats, vetch and oats, flax and potatoes. All the crops except spring wheat responded very favorably. Spring wheat responded to fertilizer applications (18 tons per hectare) or when following clover. J. S. Joffe

Fertilizer and crop rotation experiments. T. E. Odland, S. C. Damon and J. L. Tennant. R. I. Agr. Expt. Sta., *Bull.* **224**, 5–42(1930).—Very satisfactory yields of

all crops have been maintained without the use of stable manure in the non-manure rotations. The greatest gain from including legumes in the rotation was realized on the hay crops. Reducing the P in the fertilizer by 50% did not reduce the yields of potatoes or hay, but did materially reduce the yields of the following corn crop. Corn yielded as well on low K plots as on the high K ones, but potatoes, hay, alfalfa, and clover showed markedly reduced yields when sufficient K was not furnished. Moderate N applications proved beneficial to all crops except potatoes, in which case, high applications were harmful. Increasing the amts. of the same fertilizer indicate that 700–1000 lb. of a 4-8-7 fertilizer was sufficient for corn; 2000 lb. for potatoes; 700 lb. for rye; and 1050 lb. for hay. C. R. FELLERS

Ammonium calcium balance: A concentrated fertilizer problem. L. G. WILLIS AND J. R. PILAND. *Soil Science* **31**, 5-23(1931).—Pot culture expts. were made with a sandy Norfolk soil of low absorptive capacity to study the toxicity of $(NH_4)_2HPO_4$, KNO_3 and KCl to cotton seedlings. The rate of application was 9.6 lb. per acre of a fertilizer analyzing 17.5% N, 35% P_2O_5 and 17.5% K_2O. Injury to seedlings was related in some way to $(NH_4)_2HPO_4$. Free NH_3 formed by hydrolysis appeared to be the most toxic factor. No injury was observed from the use of $(NH_4)_2SO_4$, NH_4Cl or NH_4NO_3, nor did the alky. of the $(NH_4)_2HPO_4$ appear to contribute to the injurious effect. Ca salts, and also Mg salts to some degree, were antagonistic to the NH_3 toxicity. The conversion of free NH_3 to $(NH_4)_2CO_3$ in the soil and its partial neutralization by reaction with Ca salts could account for the greater part of the beneficial effect of Ca salts but physiological antagonism was probably also a factor. $NH_4H_2PO_4$ alone produced a lesser degree of injury than did $(NH_4)_2HPO_4$. This relation was, however, reversed when $CaSO_4$ was admixed. M. S. ANDERSON

Effect of fertilizers on cranberry land. CHARLES S. BECKWITH. N. J. Agr. Expt. Sta., *Bull.* **501**, 3-16(1930).—The cranberry bog, because of its peculiar soil and water conditions, requires a special fertilizer mixt. Mud bottom cannot be safely treated with com. fertilizers unless the vine growth is very poor, and then only occasionally. Feore bottom, when the vine growth is poor, can be treated every 4 or 5 yrs. with 500 lb. of complete fertilizer to the acre with good results. Thirty pounds of N can be used efficiently on poor savannah land. On savannah land, $NaNO_3$ gave large increases during the first 5 yrs. as compared with dried blood, but during the remainder of the test, dried blood gave larger increases. About half of the N should be in the form of $NaNO_3$. Fertilizer applications increase the size of the berries and improve their keeping quality. C. R. FELLERS

The perspective of nitrogen fertilizers in the northern part of Ukrainian chernozem. S. P. KULZHINSKII. *Udobzenie i. Urozhai* (*Fertilizers and Crops*) **2**, 168–75(1930).—A comparison of the relative effectiveness of $NaNO_3$ and $(NH_4)_2SO_4$ with potatoes and sugar beets has shown that Chili saltpeter was superior. The applications which were made in connection with P and K fertilizers ranged from 15 kg. to 90 kg. per hectare. The sugar content in beets fertilized with $(NH_4)_2SO_4$ was lower than in those fertilized with $NaNO_3$. J. S. JOFFE

Nitrogen fertilization of wheat. A. DRAGHETTI, A CURINI-GALLETTI AND C. VIVIANI. *Ann. staz. sper. agraria Modena* [N. S.], **1**, 31-68(1930).—Field expts. were conducted for 3 yrs. on soils very low in N; Gibertini's method (wintry fertilization) is used with Ca phosphates, $CaCN_2$ and K_2SO_4. The wintry nitrification permits the regular adsorption of the salts, independently from the external conditions, and the method is very useful in very hard winters. G. A. BRAVO

The diphenylamine and brucine reagents in the control of nitrogen fertilization of wheat. A. DRAGHETTI. *Ann. Stas. sper. agraria Modena* [N. S.], **1**, 133–51(1930).—The sensitivity of the reagents was examd. Diphenylamine is the most sensitive, giving a pos. reaction with 0.001% KNO_3 soln. G. A. BRAVO

The forms and rate of application of nitrogenous fertilizers for oats. A. L. VELIKOLEPOV. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 93–6(1930).—$NaNO_3$, $(NH_4)_2SO_4$, and $CaCN_2$ with phosphates, with lime, with both of them and without either one were tested as sources of N. The rates varied from 30 kg. to 120 kg. of N per hectare. It was found that with oats the best combination was N (in either form) with Ca and the combination of lime and P. The P alone did not show such good effects. High applications (120 kg. per ha) of $NaNO_3$ favored the availability of P. $(NH_4)_2SO_4$ with lime and phosphates was more effective than either $NaNO_3$ or $CaCN_2$. Very high applications of N favored greatly the yield of straw, much more than the grain. J. S. JOFFE

The action of nitrogen fertilizers on the yield and nicotine content of Nicotiana rustica. M. GÓRSKI AND S. KLARNER. *Roczniki Nauk Rolniczych i Lesnych* **24**, 208

(1930); cf. *C. A.* **24**, 5916.—Field expts. were made with increasing amts. of $NaNO_3$ and $(NH_4)_2SO_4$. With the application of $NaNO_3$ the yield increases nearly proportional to the quantity of fertilizer. $(NH_4)_2SO_4$ acts much more weakly than $NaNO_3$, especially with larger quantities; this is apparently due to its physiol. acidity. N fertilizing has a decided influence on the N content of *Nicotiana rustica* and therefore $(NH_4)_2SO_4$ is less suitable than $NaNO_3$. JOHN R. HILL

Relation of nitrogen fertilizer to the firmness and composition of strawberries. J. S. SHOEMAKER AND E. W. GREVE. Ohio Agr. Expt. Sta., *Bull.* **466**, 3–20(1930).—The Premier variety of strawberries produced slightly softer fruit when fertilized with spring applications of N. No significant results were obtained as to differences in moisture content or in shipping quality. N application appreciably increased the N content of the fruit; similarly, catalase activity was increased. The p_H value of the juice of berries from the N plots was consistently higher than that of the control plots. The content of reducing sugars, sucrose and total sugars increased with successive pickings. The reducing and total sugars of strawberries decreased in amt. where N was added; sucrose showed no consistent change. Late summer or fall fertilization, rather than spring, is recommended. C. R. FELLERS

Phosphorus fertilization of meadow land. II. E. TRUNINGER. *Landw. Jahrb. Schweiz* **43**, 653–98(1929).—Fertilization for 10 yrs. with 90 kg. P_2O_5 per hectare annually did not produce phosphate satn. in the top layer. Various types of P fertilizer were compared; application of superphosphate to acid soil is not recommended. B. C. A.

The response of winter wheat to phosphorus in the form of raw phosphates. F. V. CHIRIKOV. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 96–8(1930).—From a series of tests with phosphates on degraded chernozem it was found that for winter wheat an application of 90 kg. of P_2O_5 as raw phosphate was equal to 45 kg. of P_2O_5 as superphosphate. It was also found to be effective on some deep chernozems. J. S. J.

The influence of gypsum on the availability of phosphoric acid from raw phosphate A. G. MIKHALOVSKII. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 99–102(1930). Results of pot expts. on degraded chernozem with millet are: A double application of raw phosphates gave just as good results as a single application of sol. phosphate. A triple application was less effective. S is effective in solubilizing raw phosphates. The application was 2 g. of S per 3.5 kg. of soil. Equiv. amts. of S in the form of gypsum gave just as good results. J. S. JOFFE

Complete weed-eradicating fertilizers and their distribution. G. JAGUENAUD. *Compt.-rend. acad. agr. France* **16**, 1089–94(1930); cf. *C. A.* **23**, 3535; **24**, 195. A 3-5-6 mixt. is recommended for soils poor in N and a 1-4-6 mixt. for soils contg. more N. The efficiency of fertilizers as weed eradicators can be increased by the addn of $(NH_4)_2SO_4$. The best results were obtained with the 1-4-6 mixt. to which had been added $(NH_4)_2SO_4$ in proportions varying from $^1/_4$ to $^1/_{10}$ of the mixt. This mixt. should be prepd. just before application and should be dusted while the leaves are moist. J. R. ADAMS

Feeding value of alfalfa hay treated with calcium arsenate. H. J. FREDERICK. Utah Agr. Expt. Sta., *Bull.* **223**, 8 pp.(1930).—Alfalfa hay, dusted with 3–6 lb. of Ca arsenate to the acre and fed for 40 days to horses, cattle, and sheep with no other feed except water and salt, showed no actual injurious effects on livestock. Alfalfa dusted with 2 lb. of Ca arsenate to the acre, the amt. commonly used for destroying alfalfa weevil, may be fed to livestock with impunity for at least 1 feeding season. Where treated alfalfa hay was fed, more water but not so much hay was consumed, as As in the treated hay seemingly acted as a stimulant or tonic for the animals. C. R. F.

The composition of commercial calcium arsenate. C. M. SMITH AND C. W. MURRAY. *Ind. Eng. Chem.* **23**, 207–8(1931).—The av. analysis of 16 com. calcium arsenates is given and an av. mol. quotient CaO/As_2O_5 of 3.4 is obtained. This establishes the presence of a basic arsenate. The av. com. product contains 80 to 85% of what is probably a mixt. of $Ca_3(AsO_4)_2$ and this basic arsenate, together with about 6.5% each of $Ca(OH)_2$ and $CaCO_3$ and small amts. of other impurities. J. R. ADAMS

Calcium arsenate as a universal preparation against injurious insects. N. SAKHAROV. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 114–5(1930).—Tests with Ca arsenate dusting (38% As_2O_5) on mustard and sugar beets gave very good results against the various insect pests. J. S. JOFFE

A preliminary summary of investigations for the year 1929 on the effectiveness of various chemical methods in combating insect pests and diseases which attack plants. G. D. UGRYUMOV AND I. I. TRAUT. *Udobrenie i Urozhai (Fertilizers and Crops)* **2**, 45–53(1930).—The authors discuss the results of expts. on the methods of treating grain against wet smut, extermination of rodents, and measures against insect pests.

With the smut it was found that the order of effectiveness of the various substances was: Hg poisons (germisan, trillantin), formalin, Cu sulfate, arsenates, Paris green, Cu carbonate and K chromate. For the extermination of rodents chloropicrin gave better results than CS_2 in most of the regions, except Siberia. Ca cyanide gave even better results than chloropicrin. *p*-Dichlorobenzene was used successfully against fleas in the nests of the rodents. Tl sulfate, F prepns. and strychnine were used as bait; strychnine was most effective. The Tl sulfate gave good results with rats. The Na compds. of F proved even better than As compds. against insect pests. A series of tests was made with polysulfides and the Ba salt proved to have higher fungicidal power than the Na or Ca. Besides it does not burn the leaves. As to sticking qualities a mixt. of Ba polysulfide and Bordeaux mixt. (only 0.5% Cu sulfate) gave very good results. Soil disinfection was also studied. It was found that the character of the soil and amt. of rainfall are of primary importance. Sandy soils lend themselves to disinfection better than heavier soils. *p*-Dichlorobenzene on heavy soils proved to be a failure. Polychlorides which have a higher vapor pressure and a high toxicity have a higher killing power than *p*-dichlorobenzene. The introduction of polychlorides in the upper soil horizons against phylloxera proved to be very effective. J. S. JOFFE

New protection against stored-grain insects. W. P. FLINT AND C. O. MOHR. Ill. Agr. Expt. Sta., *Bull.* **359**, 377–88(1930); cf. *C. A.* **24**, 3596.—Some of the common oil emulsions and miscible oils used in spraying fruit trees will protect ear corn dipped in these mixts. from attack by many insects that injure stored grain. The highly refined oils were equally effective and did not injure germination. Boiled home-made lubricating oil emulsion was very effective in protecting ear seed corn against damage by insects. K oleate in the emulsions did not injure germination. Preliminary feeding tests indicate that the treated corn can be fed to hogs, cattle, horses and chickens without harmful effect. C. R. FELLERS

Carbolineum as insecticide from the physicochemical standpoint. S. JENČIĆ. *Arhiv hemiju. Farm.* **4**, 176–93(193–4 German)(1930). -Reference is made to the work of Chwala, Houben and Hillgendorff, Trappmann and others. The various tar emulsions, found on the market, their stability, evaluation and analyses are discussed. As the toxicity is closely related to their ability to form stable emulsions, the stability, the fixing and adhering ability of various grades were investigated in some detail. J. KUČERA

The determination of pyrethrins in pyrethrum-base insecticides. LS. A. DESHUSSES AND J. DESHUSSES. *Mitt. Lebensm. Hyg.* **21**, 304-12(1930).—The Tattersfield-Hobson method (*C. A.* **23**, 5538) gives errors of 3% for pyrethrin 1 and 7% for pyrethrin 2 With emulsions the emulsion is broken by the addn. of $MgCl_2$ or $CaCl_2$, excess of plaster of Paris is added and the dried mass extd. with pure ether, which gives satisfactory checks. F. L. SEYMOUR-JONES

Control of celery blights. J. D. WILSON AND A. G. NEWHALL. Ohio Agr. Expt. Sta., *Bull.* **461**, 3–30(1930).—Spraying with a 5-5-50 Bordeaux mixt. and dusting with a 20-80 $CuSO_4$, H_2O-$Ca(OH)_2$ dust were equally effective methods of control of celery blight (*Septoria apii*). The use of oil spreaders did not materially increase the efficiency of the Bordeaux mixt.; similarly kaolin and infusorial earth were of doubtful value as adhesives for the spray or dust. Increasing the metallic Cu content of a dust over the usual 7% increased somewhat, its fungicidal efficiency, though not sufficiently to pay for the increased cost of the Cu. C. R. FELLERS

Combating damping-off of tomatoes by seed treatment. JAMES G. HORSFALL. N. Y. Agr. Expt. Sta., *Bull.* **586**, 3–22(1930).—Seeds soaked in a $CuSO_4$ soln., 1 lb. in 8 gals. of H_2O, for 10 min. to 24 hrs., gave a remarkable increase in stand and freedom from disease of the merged seedlings in greenhouses. Tomato seeds are extremely resistant to Cu injury for they can successfully stand in a 7.2% soln. of $CuSO_4$ for 2 hrs without injury. Seedling plants may be injured by as little as 0.5% soln. applied to the soil at the rate of 1 qt. per sq. ft. A $CuCO_3$ dust also gave good results in disease control. $Cu(CN)_2$ caused serious germination injury as did calomel, HgS, HgO, Semesan, Ceresan and Dipdust. C. R. FELLERS

Sodium acid sulfate as a disinfectant against Salmonella pullorum in poultry-yard soils. P. W. ALLEN AND M. JACOB. Tenn. Agr. Expt. Sta., *Bull.* **143**, 3–14(1930).—Poultry was protected against infection from contaminated soil when a 5% soln. of $NaHSO_4$ was applied to the soil at the rate of 1 gal. to 1 sq ft of soil. No harmful effects on the fowls were noted There was little or no detrimental effect on the growth of grass. There is some evidence that the $NaHSO_4$ is of value in controlling internal parasites in poultry. Undesirable properties are: corrosion of metals, destructiveness to cloth and irritation of hands. The sterilizing effect of $NaHSO_4$ is attributed to the free acid content. C. R. FELLERS

Control of bunt or stinking smut of wheat. F. D. HEALD AND E. F. GAINES Wash. Agr. Expt. Sta., *Bull.* **241**, 5–30(1930).—$CuCO_3$ when used at the rate of 3 oz. per bu. for treating spring wheat gave an av. control of 99.55% against bunt (*Tilletia* sp.). Of the 17 samples of $CuCO_3$ tested, none was markedly superior. Both $CuSO_4$, 20% soln., and 1 to 320 CH_2O, when applied for 10 min. to winter wheat seed, gave moderately good results, but not nearly as good as with spring wheat. A new com. org. Hg disinfectant called Ceresan was fully as effective as $CuCO_3$ in protecting wheat from bunt infection. The use of bunt-resistant varieties of wheat is recommended, especially for winter sowing. C. R. FELLERS

Influence of fertilization on the baking quality of bread cereals (NEUMANN, NOLTE) **12.** N and its compounds (JOHNSON) **18.** The electrolytic production of $CaHPO_4$ from apatite in India (DAS) **4.** Domestic and foreign experiences of biological treatment of garbage [use as fertilizer] (VAN LOGHEM) **14.** Enriching Khibinsk apatite by flotation (ERCHIKOVSKII) **18.** Polymerization and solubility of phosphates (DRAGUNOV) **18.** The composition of sugar beets in various crop rotations (NADEZHDIN) **28.** Utilization of agricultural wastes (GILMAN, *et al.*) **10.** Fumigant solution (U. S. pat. 1,790,095) **17.** Preserving granular substances containing unstable substances (Fr. pat. 692,266) **13.** Compositions for combating animal or vegetable pests, particularly for treating seeds (Ger. pat. 514,284) **18.**

Lime nitrogen. CARL EHRENBERG. Ger. 514,253, Aug. 26, 1928. A granular product is prepd. by mixing lime nitrogen with about 15% of a dry humate, preferably an alkali or NH_4 humate, compressing the mixt. into briquets, and granulating the briquets.

Urea. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 335,421, Nov. 13, 1928. A suitable NH_3-CO_2 compd. is mixed with an indifferent viscous liquid of high b. p., such as transformer oil, and brought under pressure at an elevated temp. (a pressure of 100 atm. and temp. of 150–200° are used) with or without presence of a catalyst. Unconverted NH_3 and CO_2 may be recovered from the product by distn. and an aq. soln. of urea sepd. from the oil. Addnl. substances may be introduced at different stages in the course of the process to form mixed *fertilizers*.

Carbon dioxide fertilizer plant. FRIEDR. RIEDEL. Ger. 511,809, May 3, 1928. The plant consists of a coal-burning furnace to produce the CO_2 mixt. and an irrigation tower up which the gas passes against a current of water to remove constituents harmful to plants. Cf. *C. A.* **25**, 1026.

Dicalcium phosphate. A. HOLZ and T. VAN D. BERDELL. Brit. 335,007, July 30, 1929. Rock phosphate is treated with a mixt. of HCl and H_2SO_4 in equiv. proportions. $CaSO_4$ is filtered off and the filtrate contg. H_3PO_4 and $CaCl_2$ may be treated with NaOH and $Ca(OH)_2$ to form di-Ca phosphate and a soln. of alkali metal chloride. The acid mixt. used may be produced by electrolyzing a soln. of alkali metal chloride and passing the Cl evolved with an equiv. proportion of SO_2 into water (the alkali metal hydroxide formed being also used in the process). Various details and modifications of procedure are described. Cf. *C. A.* **24**, 4889.

Converting phosphoric acid into a product suitable for transportation and for use as a fertilizer. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 45,688, Oct. 15, 1928. H_3PO_4 is mixed with SiO_2 or silicates and the mixt. is heated to temps. not exceeding 650°. Compds. of the type $xP_2O_5.ySiO_2$ are obtained which contain the P_2O_5 in water-sol. form.

Fertilizer. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 45,714, Oct. 22, 1928. "Silica-phosphate" (cf. preceding abstract) is used in mixt. with other fertilizing materials, the plant nutrient substances of which are converted into a more sol. or, in other respects, more suitable form by means of the phosphoric acid.

Fertilizer. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 46,524, June 3, 1929. A mixt. of NH_4NO_3 and $CaCO_3$ is heated with const. stirring, in the presence of moisture, until agglomeration takes place.

Fertilizers. SIEMENS & HALSKE A.-G. (Georg Erlwein, inventor). Ger. 513,416, Sept. 13, 1928. The product obtained by opening up crude phosphate with HCl in known manner is heated in an elec. induction oven. P vapor is evolved, and is passed to a reaction vessel supplied with H_2O and Cl gas, a mixt. of H_3PO_4 and HCl being produced. This mixt. is sepd. by distn., and the H_3PO_4 is either converted into $(NH_4)_2HPO_4$ or reacted with crude phosphate. The HCl is used again in the process.

Fertilizers. I. G. FARBENIND. A.-G. Fr. 690,870, Mar. 1, 1930. Solid $(NH_4)_2HPO_4$ is made by drying a concd. soln. of $(NH_4)_2HPO_4$ after mixing it with solid $(NH_4)_2HPO_4$. If a fertilizer is required one or more fertilizing salts are added before drying.

Fertilizers. SOC. VILAIN FRÈRES. Fr. 691,396, Feb. 28, 1930. Mg rocks such as giobertite, magnesite, periclase, carnallite, kainite, serpentines, steatites and dolomite are sorted, washed, treated with a mineral acid such as HCl, HNO_3, H_2SO_4 or H_3PO_4 or with an acid salt or at a high temp. with CO_2, NH_3, H_2SiO_3, C, N, etc. The products are used directly as fertilizers or for the prepn. of complex NH_4-Mg fertilizers. Cf. *C. A.* **24**, 2539.

Protecting agent and stimulant for plants, etc. KURT LEVIN Ger. 514,155, April 1, 1926. A protecting agent and stimulant for wet or dry application to plants or seeds comprises MnF_2 or its addn. compds., *e. g.*, $KMnF_3$ or NH_4MnF_3, alone or with other stimulants, fungicides, diluents, etc.

Insecticide. ALBERT P. SACHS (to Larvex Corp.). U. S. 1,789,565, Jan. 20. A compn. for moth-proofing textile materials comprises Na_2SO_4, NaF and a bitter ext. such as ext. of aloes or quassia.

Insecticide. RURIC C. ROARK and RICHARD T. COTTON (to the Government and People of the U. S. A.). U. S. 1,789,322, Jan. 20. A non-inflammable mixt. is formed by mixing a non-inflammable liquid such as CCl_4 or C_2Cl_4 with an ester of a halogenated aliphatic acid such as Me, Et, iso-Pr or Bu monochloroacetate. The mixt. is suitable for use as a spray, for fumigating grain, etc.

Insecticide. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Herbert Schotte, inventors). Ger. 512,871, Feb. 9, 1929. Insecticides contg. poison and hormone-like substances are described. Examples mention thyroxine with $Ca_3(AsO_4)_2$, and $Cu(OH)_2$, and hormone prepns. from mammals blood with As_2O_3.

Insecticides. STANDARD OIL DEVELOPMENT CO. Fr. 690,775, Feb. 27, 1930. An insecticide is composed of a white petroleum oil, an ext. from a plant having insecticide properties, such as the pyrethrum type, and an emulsifying agent. Cf. *C. A.* **24**, 2849.

Emulsions of oil and water suitable for spraying trees and plants. CHARLES E. OLIVER. U. S. 1,790,070, Jan. 27. A mixt. of oil and rosin is mixed with an aq. casein soln. separately prepd.

Protecting potatoes against rot. CHEMISCHE FABRIK VON HEYDEN A.-G Ger. 514,045, Dec. 31, 1926. Sulfohaloamides or their salts are applied to the soil. The Mg salt of *p*-toluenesulfochloroamide is specified.

Facilitating germination of seeds. WARREN-TEED SEED CO. Brit. 335,102, Nov. 15, 1928. Seeds such as those of clover, alfalfa, onion or sweet pea are soaked for 20–60 min. in a liquid such as a saccharin soln., preferably at a temp. of 20–45°; the swelled seeds are sepd. by screening and use of a current of water and the remaining seeds are moderately scarified and again soaked and the swollen seeds are sepd. and the remaining seeds scarified, the seeds being subsequently mixed together and sown. A 22° Bé. glucose soln. may be used for the soaking. Weed seeds that do not readily swell are sepd. when the swollen seeds are removed after the last scarification.

Immunizing seed grain. I. G. FARBENIND. A.-G. Brit. 334,847, May 1, 1929. In treatments such as immunizing seed wheat from stone blight, there are used hydroxy diaryl- and triarylmethane compds. contg. one or more halogen phenol radicals such as the product obtained by condensing formaldehyde with 2 mol. proportions of *p*-chlorophenol in the presence of H_2SO_4 or similar compds. (which may be mixed with a diluent such as powd. talc). Several examples are given.

Apparatus for generating gases for fumigating grain, etc. JOHN FOX. U. S. 1,790,139, Jan. 27. Structural features.

Fungicides for seeds. I. G. FARBENIND. A.-G. (Wilhelm Bonrath, Karl Marx, Carl Taube and Karl Brodersen, inventors). Ger. 514,210, Aug. 17, 1929. Quinoneimides or their derivs. are used, alone or with other fungicides, diluents, adhesives or wetting agents.

Fungicides for seeds, etc. IGNAZ KREIDL. Austrian 119,968, June 15, 1930.

Insol. or difficultly sol. fungicides for dry application to seeds, etc., are mixed with hygroscopic compds., preferably such as will convert the fungicides into sol. compds. Thus, $CuCO_3$ 3 may be mixed with $Ca(NO_3)_2$ or $CoCl_2$ 1 part.

Cauterizing agent for seed goods. I. G. FARBENIND. A.-G. (Adolf Steindoff, Kaspar Pfaff and Paul Igler, inventors). Ger. 512,951, April 29, 1926. The prepn. contains mercurized arylarsonic acids or salts. Mercurized 3-acetamido- or 3-nitro-4-hydroxyphenylarsonic acids are mentioned as examples. Cf. *C. A.* **25**, 768.

Compositions for killing weeds. R. N. CHIPMAN. Brit. 335,203, Dec. 22, 1928. Weed-killing compns. such as solns. of Na, K or Ca chlorates are rendered more efficient by making them neutral or acid by the addn. of various specified common inorg. or org. acids or acid salts. Cf. *C. A.* **24**, 2828.

Animal dip. KARL BRODERSEN and WERNER EXT (to Winthrop Chemical Co.) U. S. 1,789,668, Jan. 20. A dip suitable for treating sheep comprises Na arsenite, colloidally dispersed As_2S_3, colloidally dispersed S and cell pitch (from sulfite cellulose liquor). Cf. *C. A.* **24**, 213.

Animal pest preventative. I. G. FARBENIND. A.-G. (Karl Marx and Karl Brodersen, inventors). Ger. 511,544, Mar. 7, 1929. The prepn. contains alkylene oxides which have at least 3 C atoms and which boil below 100°, so that they give off vapor at relatively low temps. to prevent, *e. g.*, the attacks of grain weevil. C_2H_4O and C_3H_6O are mentioned as examples.

Combating subterranean pests. ALEX DERICHSWEILER. Ger. 483,066, Mar. 30, 1926. CH_2O, C_6H_6 or other disinfectant is absorbed in calcined Na_2SO_4 or other suitable salt, and the granules of the non-coherent mass so obtained are coated by treatment with concd. waterglass. The compn. is then applied to the soil.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Formation of acids during fermentation. W. WINDISCH, P. KOLBACH AND R. ILLIES. *Wochschr. Brau.* **47**, 417–21, 427–31, 437–41(1930).—The Windisch, Reimers and Hirschbruch method for detg. esters in beer is improved. The influence of the CO_2 upon these tests is eliminated. Different mashes were prepd. by changing the p_H, resulting in worts with various p_H values and N contents. The fermentation of these worts did not show a regular correlation between acid formation and compn. Worts started with identical p_H showed some correlation in acid formation and NH_3 consumption insofar as the strongest acid formation was observed on the samples with highest NH_3 consumption. The compn. of the wort was changed on 2 malt samples by using different mashing processes. Mashing with a long protein rest increased the action of proteases and phosphatases. One of the 2 malt samples examd. showed less acidity with longer protein rest; no such correlation, however, was found on the other sample. It was found that the changes in mashing affected the compn. of the wort in so many respects that the effect of the individual factors on the fermentation could not be detd. Therefore, later expts. were confined to a study of the effect of acidity. The p_H was adjusted by NaOH and HCl. The assertion that yeast tends to produce a certain optimum acidity regardless of the acidity of the wort could not be confirmed. The effect of different acids (HCl, H_2SO_4, H_3PO_4 and lactic acid) upon the acid formation was studied, but no differences were found. Addn. of increasing amts. of AcOH seems to cause a const. decrease of the acidity during fermentation. The reasons are discussed. Increasing amts. of buffer with the same starting p_H raised the acidity during fermentation with non-fermentable buffer salts. The formation of esters is considered to be of minor importance. Correlation between total-N and formol-N assimilation, resp. and acid formation could not be detected. S. JÓZSA

The present position of citric acid fermentation. ALFRED FREY. *Chem.-Ztg.* 55, 40(1931). E. H.

Xylose as a nutritive substratum for citric acid fermentation. ALFRED FREY. *Z. angew. Chem.* **44**, 16–21(1931).—Xylose wort prepd. by the Scholler-Tornesch method must be purified to use as a substrate for citric acid formation by *Citromyces*. Furfural and other aldehydes must be removed by steam distn. or by treatment with active charcoal. By increasing the area of reaction the acid yield can be raised to 20% of the added reducing sugar. The addn. of $CaCO_3$ increases the yield. The amt. of acid is only a fraction of the 50% yield possible with pure sugar. MARY E. LEAR

Fermentation of molasses produced from refined sugar factories. N. TAKETOMI

AND T. MATSUMOTO. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 531(1930).—The low yield of EtOH from fermentation of Formosan cane molasses is due to the presence of glutose, and in some cases to insufficiency of nitrogenous yeast nutriment (*J. Soc. Chem. Ind, Japan* **30**, 389, 109B; **31**, 856, 206B). NH_4 salts increase greatly the fermentation velocity of refined sugar molasses, but Mg and Ca salts and K diphosphate have no noticeable effect. A suitable amt. of $(NH_4)_2SO_4$ or NH_4 phosphate is 0.1–0.4 g. per 100 cc. of 16.5–17.5° Brix molasses. Refined sugar molasses contains 4.5–6% of glutose, an unfermentable hexose. Glutose phenylosazone was prepd. and photomicrographs are shown. E. M. SYMMES

New process of drying potatoes and the manufacture of alcohol therefrom. B. LAMPE AND W. KILP. *Z. Spiritusind.* **53**, 191–3, 199–200(1930).—The process combines drying plant and distillery processes. One part of potato juice is obtained from 2 parts of washed macerated potatoes. The remainder of the potato pulp contains 60% of moisture. The potato juice, which contains a considerable amt. of salts, proteins and small quantities of starch, will be utilized in the distillery as a mashing liquor to soak and saccharify the dried potatoes. The pulp is dried carefully and the temp. is not allowed to go above 50° during the first 3 hrs. Thereafter it is gradually raised to 100°, resulting, after 6 hrs. of total operation, in potato flakes of 14% moisture. The use of the juice as mashing liquor makes low mashing temps. possible and a slope of high feeding value is obtained. Three different mashing processes were studied on a lab. scale, and their yield results are given. Practical directions to be followed in processing dried potatoes for distilleries with and without the use of potato juice are finally given. S. JÓZSA

The determination of extract and sugar in wine vinegar and cider vinegar with consideration of the presence of acetylmethylcarbinol. J. PRITZKER AND ROB. JUNGKUNZ. *Mitt. Lebensm. Hyg.* **21**, 354–62(1930); cf. *C. A.* **20**, 2386.—Indirect extn. by the Swiss official methods gives equal or higher results than the direct extn., because of the presence of acetylmethylcarbinol (*A*) in vinegar, which also affects the detn. of sugars because of its reducing action on Fehling's soln. *A* can be detd. by oxidizing it to the diacetyl compd. with $FeCl_3$ and pptg. it as the Ni dimethylglyoxime. In detg. sugar in vinegar *A* must be removed by repeated evapn. with added water. F. L. SEYMOUR-JONES

Monoiodo- and monobromo-acetic acid poisonings in carbohydrate breakdown. RAGNAR NILSSON, KARL ZEILE AND HANS V. EULER. *Z. physiol. Chem.* **194**, 58–68 (1931).—Poisoning of dried yeast by ICH_2CO_2H or $BrCH_2CO_2H$ suppresses the formation not only of hexosediphosphoric acid but also that of hexosemonophosphoric acid. NaF under the same conditions suppresses only the hexosediphosphoric acid formation. A further difference between ICH_2CO_2H and NaF poisoning is the absence of AcH reduction in the presence of glucose and hexosediphosphoric acid when ICH_2CO_2H is added. Lundsgaard's observation (*C. A.* **24**, 3256) that the respiration and the fermentation functions of yeast can be sepd. by ICH_2CO_2H poisoning is corroborated. The sepn., however, is possible only with a definite concn. of the poison; with higher concns. the respiration also is inhibited. Reduction of methylene blue is likewise suppressed by the higher concns. The inhibition of fermentation without impairment of respiration probably does not involve the entire anaerobic reaction chain. It may be that the fermentation process stops just short of its final stage where the remaining step is not essential to respiration. A. W. DOX

Metafiltration and the brewing industry. J. A. PICKARD. *J. Inst. Brewing* **36**, 179–88(1930).—It is possible to filter beer so that it is sterile on leaving the filter. For hazy beers some metisil is added to the beer during filtration. The filter is cleaned by reversing a flow of water through it and draining the loosened cake. PETER J. F. WEBER

Comparative brewing trials with certain new and commercial varieties of hops. W. T. SMITH AND A. J. C. COSBIE. *J. Inst. Brewing* **36**, 91–6(1930); cf. *C. A.* **22**, 1430; **23**, 1463.—Brewery trials of some hybrids of Continental and Oregon hops with English male hops produced beers with hop flavor which resembled the foreign parents, and indicated that these hops should be judged as substitutes for foreign hops, rather than compared with the differently flavored English hop varieties. The brews also proved conclusively the superiority of the brew method of judging flavor over any other method, and showed particularly the limitations of hand examn. P. J. F. W.

Notes on hop drying in the Saaz and Hallertau Districts. A. H. BURGESS. *J. Inst. Brewing* **36**, 97–8(1930).—Kiln drying of hops appears to have entirely superseded the old practice of drying without artificial heat. Kilns used were of the "Linhart" and "Saazia" type; they are described in detail. PETER J. F. WEBER

An investigation of the desirability of extra-compression of hops. T. K. WALKER, J. J. H. HASTINGS AND A. G. ALDOUS. *J. Inst. Brewing* 36, 99–104(1930).—Hops which were compressed to a vol. half the normal size, without inflicting mech. damage, deteriorated so much less that the extra-compressed hops stored in an ordinary warehouse had preservative power and appearance equal to normally pressed hops in cold storage. When similarly stored the extra-compressed hops showed up better than the ordinary pressed hops. PETER J. F. WEBER

The chemical composition of the 1927 barley crop and malt and the worts and beers made therefrom. W. WINDISCH, P. KOLBACH AND E. SCHILD. *Wochschr. Brau.* 47, 357–61, 369–74, 381–4(1930).—The expts. were similar to those carried out on the 1926 barley crop (cf. *C. A.* 23, 4528). The formation of NH_3 was followed from barley to beer. The formation of volatile acids was detd. in wort and beer. The total P content was detd. in barley and in malt and also in their infusions. The org. P and the P not precipitable by Ba were also detd. on these infusions. The results are summarized. S. JÓZSA

Effect of varying the steeping period on barley. C. H. JOYCE. *J. Inst Brewing* 36, 131(1930).—Analyses are given of malts made with 4 types of barley which had been steeped for varying lengths of time. PETER J. F. WEBER

Technology of malting. Beers from floor malt and compartment malt. E. JALOWETZ. *Brau- und Malzind.* 23, 185–6(1930).—The biol., phys. and chem. examn of beers brewed from malts which have been produced from the same barley under comparable malting conditions by the flooring system and by the compartment system, gave values in very close agreement. S. L.

Technology of malting. IX. Comparative investigation of floor malt and pneumatic malts. (a) Drum malt. E. JALOWETZ. *Brau- und Malzind.* 23, 99–102 (1930); cf. *C. A.* 25, 555.—Comparative malting expts. were carried out on the same barley by means of the flooring system and by means of the drum system The mech. and chem. analyses showed that the 2 resulting malts were of equal quality and quant. compn. **(b) Compartment malt.** *Ibid* 167–71.—Equal results were obtained when the barley was malted under comparable conditions by the flooring system and by the compartment system Tables with analysis are given. **X. The influence of different steeping periods and germination temps. on the malt quality.** *Ibid* 205–8.—The quality of malt was not affected when the time of steeping and the germination temp. varied within certain limits. S. LAUFER

Musts and wines of the Modena Province. R. CARTENY. *Ann staz. sper. agrar. Modena* [N. S.], 1, 183–8(1930).— Analyses of the musts of 1928 and 1929 gave, resp. reducing sugars 16.5, 21.0%, total acid (calcd. as tartaric acid) 0.35, 1.30%. Analyses of wines of 1928 and 1929 gave, resp.: alc. 5.0–11.0, 8.0–14.5%, total acid 0.45–1.25, 0.5–1.1%. G. A. BRAVO

Experiments on different glasses used in bottle manufacturing. G. KEPPELER. *Wochschr. Brau.* 47, 352–4(1930).—K. analyzed 35 different glasses and concludes that chem. changes are not responsible for the changes taking place in bottles. He found that the color of the glass is very important. The spectral analysis revealed that in glasses transmitting a larger no. of short waves the beer showed increasing turbidity. Protein content and p_H were exactly checked on each sample and no differences were found. The haze which appeared in the bottles was found to be due to an increased pptn. of hop tannins and proteins. Brown glass, which proved in several cases less resistant to the chem action of beer, was found to afford greater protection against haze formation, and this was due only to the greater light absorption S. JÓZSA

Bottle glasses [for beer] (KEPPELER, MAENICKE) **19.** Apparatus for saturating liquids with gases, particularly for making beverages (Ger. pat. 513,265) **1.** Sterilizing and pasteurizing liquids such as beer (U. S. pat. 1,790,117) **13.**

JALOWETZ, E.: **Pilsner Bier im Lichte von Praxis und Wissenschaft.** 2nd ed., unchanged. Vienna: Verlag Institut für Gärungs-industrie. 138 pp.

C. N. RIIBER: **Ratio between the Content of Dry Matter and the Specific Gravity in Wort and Beer Extract [in Norwegian].** Trondhjem, Norway: F. Brun. 22 p. kr. 1.50.

Denaturing alcohol. I. G. FARBENIND. A.-G. (Carl Müller, Leo Schlecht and Hans Rötger, inventors). Ger. 512,712, Nov. 6, 1927. Alc. is denatured by the condensation product obtained by leading NH_3 and unsatd. hydrocarbons (especially

C_2H_2, etc.) over catalyzers at high temps. Thus, 96% alc. is denatured by the product obtained by passing NH_3 and C_2H_2 over a catalyzer at 350°.

Denaturing alcohol. I. G. FARBENIND. A.-G. (Leo Schlecht and Hans Rötger, inventors). Ger. 513,410, Aug. 3, 1928. Addn. to 512,712 (preceding abstr.). Alc. is denatured by addn. of S-contg. condensation products obtained by the action of S vapor or S-yielding compds. on unsatd. hydrocarbons. Thus, C_2H_2 and H are led over pyrites at 350° and the product used to denature alc.

Concentrating alcohol. ZELLSTOFFFABRIK WALDHOF and O. LÜHRS. Brit. 335,132, Jan. 10, 1929. In concg. aq. alc., such as 94% alc., by distg. with "calcined chalk" under pressure, small pieces of "chalk" carried over by the alc. vapors are removed by passing the vapors through a layer of abs. alc. before condensation.

Acetic and butyric acids, etc., by fermentation. H. LANGWELL. Brit. 334,900, June 11, 1929. In a fermentation process in which acids such as HOAc and butyric acid are neutralized to the required extent, as formed, with NH_3 or suitable NH_3 compds. such as the carbonate or substituted ammonias, NH_3 is subsequently liberated by decompn. of the resulting salt by the action of a non-volatile base such as lime or $CaCO_3$ and is recovered by distn. (suitably in successive stages with intermediate filtration of the liquid). For the fermentation, there may be used organisms such as those derived from fermenting vegetable matter, septic sewerage, soil, corn cobs, etc.

2,3-Butyleneglycol. T. H. VERHAVE. Brit. 335,280, June 26, 1929. A suitable carbohydrate mash contg. suitable phosphatic and N-contg. substances is fermented with bacteria capable of producing 2,3-butyleneglycol and, after an initial fermentation period, the alc. which is also formed is distd. off, a new portion of mash is added, reinoculated with bacteria (unless the distn. has been at such a low temp. that this is unnecessary) and further fermentation is conducted, followed by recovery of the alc. and 2,3-butyleneglycol produced. Various details and modifications of procedure are described. Cf. *C. A.* **24**, 1652.

Coloring sugar. FÉLIX ALBRECHT. Fr. 691,704, Mar. 11, 1930. A coloring sugar for beer, liquors, etc., is prepd. by liquefying solid sugar by means of concd. aq. NH_3 and heating the liquid in an autoclave to 105–120° for some time. The product is cooled and heated again to 105–120° and the pressure is reduced. Volatile products are removed by steam and the product removed from the autoclave.

Apparatus for the continuous distillation and rectification of wines, ciders, fermented liquids, benzene, gasoline, etc. ÉMILE GAZAGNE. Fr. 691,995, Mar. 15, 1930.

Rotary heater for beer-brewing coppers. "MIAG" MÜHLENBAU UND INDUSTRIE G. Ger. 512,556, Jan. 9, 1930.

Apparatus for fermenting wort and producing pure yeast cultures. VULKAN-WERKE A.-G. FÜR BRAUEREIBEDARF. Ger. 512,555, Mar. 6, 1927. Addn. to 349,258. The wort is circulated through spent hops.

Dried potatoes. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 511,696, Feb. 13, 1929. Addn. to 498,557 (*C. A.* **25**, 1298). In drying potatoes by the method of 498,557, lactic acid pure cultures are added to the potato mash before the suction filtering process.

Yeast. VULKAN-WERKE A.-G. FÜR BRAUEREIBEDARF. Ger. 511,111, Mar. 3, 1929. In prepg. pure yeast cultures, a part of the culture is withdrawn after the fermentation into an auxiliary container from a level in the fermentation vessel at which impurities cannot settle. The yeast in the auxiliary container is used to initiate the next fermentation, after the fermentation vessel has been emptied, cleaned and recharged with fresh wort.

Yeast. M. FISCHL'S SÖHNE and FRANZ ROSENBERG. Austrian 119,946, June 15, 1930. In the manuf. of yeast by the aeration method, a quantity of seed yeast is supplied with an amt. of nutrient medium such as will enable the yeast to multiply at about the ideal rate, *i. e.*, logarithmically with the time, while substantially exhausting the nutrient medium. The yeast so obtained is used without sepn. as the initial material for a second similar fermentation and so on, the whole process thus comprising a series of fermentation "phases" of increasing vol., each phase being a complete fermentation in itself. The entire amt. of nutrient soln. required for each phase is added at the start of that phase and the process is continued until, on account of accumulation of poisons, etc., propagation at an approx. ideal rate is no longer attainable. A typical process is conducted in 7 phases of a total duration of 26.5 hrs. The theoretical basis of the method is fully discussed, and detailed examples are given. App. comprising a series of fermenting vats of successively increasing vol. is described.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Limitations of phenol coefficients of coal-tar disinfectants. C. M. BREWER AND G. L. A. RUEHLE. *Ind. Eng. Chem.* **23,** 150–2(1931).—Data from 206 samples of coal-tar phenol disinfectants are given so that a comparison can be made between the *B. typhosus* and *Staph. aureus* phenol coeffs. The data show that it is unreliable to est. the efficiency of a disinfectant against other species of pathogenic bacteria from the *B. typhosus* phenol coeff. The coeff. is limited in usefulness to comparisons of different disinfectants against the test organisms. J. R. ADAMS

Chemical and photochemical oxidation of commercial adrenaline solutions. T. VACEK. *Compt. rend. soc. biol.* **100,** 583–4(1929).—The p_H values of com. adrenaline solns. varied between 1.6 and 4.0. The rate of oxidation with H_2O_2 and in light is independent of the p_H, while an increase in the rate with increasing p_H was observed with pure solns. of adrenaline-HCl. The intensity of photooxidation depends on the intensity of the light and on the wave length; irradiation with ultra-violet light alone causes less change than that with visible and invisible rays at the same time. B. C. A.

Significance of the degree of dissociation of acids in the oxidation of adrenaline. T. VACEK. *Compt. rend. soc. biol.* **100,** 585–6(1929).—The speed of oxidation of adrenaline solns. is directly proportional to the H-ion concn. only when the same solvent is employed. B. C. A.

Pharmacognostic themes. V. Mutation, heredity and selection. L. E. GORSTER. *Pharm. Weekblad* **68,** 41–59(1931); cf. *C. A.* **21,** 3934 – A discussion of the effect o, domestication, crossing of strains, and selection on *Hyoscyamus niger, Mentha piperita* rhubarb, *Piper cubeba* and *Pyrethrum cinerariaefolium.* A. W. DOX

Peroxide formation of pharmacopeial tinctures. TAYURU ARAKAWA. *Tôhoku J. Exptl. Med.* **16,** 111–7(1930).—Many pharmacopeial tinctures give a distinct color when poured with a tincture of guaiacum into cow milk. This activity is absent in the freshly prepd. tincture, develops upon exposure to air, and is probably due to peroxide formation. H. EAGLE

Peroxide formation of alcoholic solutions of guaiacum and benzidine; its relation to hydrogen-ion concentration. TAYURU ARAKAWA. *Tôhoku J. Exptl. Med* **16,** 236–40 (1930).—The formation of peroxide in alc solns. of guaiacum is most rapid in alk. reaction (p_H 8.4) while the optimum for benzidine is at acid reaction (p_H 3.6). H. E.

Oil of Artemesia afra. G. W. B. VAN DER LINGEN. *Perfumery Essential Oil Record* **21,** 473(1930).—Steam distn. of the fresh leaves and stalks of this S. African shrub resulted in a 0.3% yield of a greenish yellow rather bitter oil, having the consts.: d. 0.9528, $n_D^{21.4}$ 1.4804, acid no. 22.12, ester no. 77.49, Ac no. 109.88. The "cold-relieving" property of the aq. plant ext. is probably due to the liberation of cineole, which has been detected in the oil. W. O. E.

Fluidextracts from domestic drug plants. LUDWIG KROEBER. *Pharm. Zentralhalle* **71,** 51–3, 148–50, 388, 533–4, 659–62(1930); **72,** 4–8, 19–22(1931); cf. *C. A.* **24,** 1465.—The following figures show, resp., d_{19}, percent dry residue and percent ash: Ext. *Cirsii olerace* 1.051, 14.14, 2.44; ext. *Rubiae tinctorum* 1.0542, 11.50, 0.56; ext. *Saniculi europaeae* 1.070, 18.60, 2.40; ext. radicis *Dentariae enneaphyllae* 1.099, 21.88, 1.92; ext. *Scrophulariae nodosae* 1.147, 17.20, 2.80; ext. fructus *Phaesoli vulgaris* sine semine 1.044, 11.90, 2.58; ext. *Droserae rotundifoliae* 1.053, 19.05, 1.25. W. O. E.

Early popular medicine. O. TONN. *Pharm. Zentr.* **71,** 582, 611–3(1930).—A few examples are cited, as the use of liver in pernicious anemia, of digitalis in dropsy, chorion in pregnancy instead of opium, human feces in dysentery, etc. W. O. E.

New physical methods for testing essential oils and related products. ARNO MÜLLER. *Riechstoffind.* **5,** 102–4, 126–8(1930).—Certain published methods for the examn. of the germicidal powers and capillary activities of essential oils are discussed in connection with M.'s method and app. (illustrated) for detg. the consts., d., surface tension and viscosity. The values obtained in the examn. of certain oils and synthetic perfume products are reported. W. O. E.

Practical suggestions in olfactory analysis. PAUL JELLINEK. *Riechstoffind.* **5,** 120–4(1930).—Among the numerous suggestions offered in the olfactory analysis of compns. are the use of paper strips of varying absorptive capacities; diln. of the samples with water or paraffin oil (thus: dil. a sufficient amt. of the sample (previously

freed from alc. by distn.) with water (100 parts) or paraffin oil (10 parts), shake vigorously, allow to stand in a cool place for purposes of clearing, transfer to a separatory funnel if 2 layers form, or if only cloudy pass through filter paper until clear). W. O. E.

From the lemon to the violet through classical chemistry. HANS MÜLLER. *Riechstoffind.* **5**, 124–6(1930).—M. traces the odor of the lemon (citral), through iris (irone) and its various synthetic substitutes to ionone. W. O. E.

Perfume ideas of modern times. C. E. WALD. *Riechstoffind.* **5**, 152–5(1930).—A discussion is given and comments are made on the modern trend in perfumes, notably certain trade-marked brands like "Quelque Fleurs," "Belle Fleurs," "Bouquet de Fleurs," etc., with suggestions for duplicating the specialty "Millefleurs" of Cerbelaud according to the formula as stated or by substitution of certain of its ingredients. W. O. E.

Characterization of perfumes by their odorous intensity and permanence. ALBERT ELLMER. *Riechstoffind.* **5**, 156–9(1930).—E. has undertaken, in the examn. of a large series of perfume materials, an enumeration of the outstanding qualities, as general character of odor, head perfume, after-odor, persistence of odor in hrs, etc. W. O. E.

Problems in fixation. PAUL JELLINEK. *Riechstoffind.* **5**, 159–63(1930).—The development, purpose and tendency in *perfume* fixation are discussed. W. O. E.

Application of the analytical quartz lamp in the investigation of perfume principles. E. EKMAN AND A. SAMYSCHLAYEWA. *Riechstoffind.* **5**, 164–5, 182–4, 196–7(1930).—A study has been made of the fluorescence phenomena produced by the quartz lamp on a series of perfume materials, as alcs., aldehydes, ketones, acids, esters and phenols, the results obtained being grouped with the characters of the materials in question. W. O. E.

Influence of altitude on rose culture. ALBERT ELLMER. *Riechstoffind.* **5**, 193–5 (1930).—A comparative study of the varying conditions under which rose culture is carried on in Bulgaria and southern France, at altitudes for the former of 0 to 1000 m. and for the latter 0 to 300 m. Notably in southern France about 20 km. above Grasse and at an altitude up to 1120 m. recent observations have shown that, while the harvest is 2 to 3 weeks later than in the lowlands, the quality of the roses obtained is in point of perfume superior, as also the quantity of oil greater, than that resulting from lower situations. W. O. E.

Lichen from Evernia prunastria. JAN HOREL. *Chem. Obzor* **5**, 322–4(324–5 English)(1930).—A lichen of *Evernia prunastria* growing in Slovakian forests on leafy trees and Coniferrae is described which serves as a raw material for the manuf. of an aromatic essential oil, called essence de mousse de chêne. This lichen, exported from Czechoslovakia to France, is extd with low-boiling solvents, purified and decolorized One hundred kg. of the lichen yields 0.2–0.3 kg. raw ext. and 20–30 g. pure essential oil. The chem. compn. of the oil is briefly discussed. J. KUČERA

Studies on uricolytic drugs. I. Lithium salts. POMPEO SPOTO. *Arch. sci. biol.* (Italy) **15**, 324–41(1930); cf. *C. A.* **24**, 4446.—The soly. of uric acid in distd. water was 0.1 g. per l. The soly. of uric acid in various concns. of Li acetate was detd. S. concludes that the soly. is related to the concn. of Li acetate and to H-ion concn. The soly. of uric acid in solns. of Li acetate at various p_H values but const. Li concn. was also detd. The results show that the increase in soly. of uric acid in the alk. range in contrast to its soly. in Li acetate alone is directly proportional to the amt. of free alkali present, an equiv. of Li was needed to dissolve an equiv. of uric acid. In the acid zone the soly. of uric acid depends on the H-ion concn. due to the dissocn. and concn. of AcOH present. The curve showing the soly. of uric acid at different H-ion concns. corresponds exactly to the neutralization curve between AcOH and an alkali. The soly. of uric acid varies little at the neutral point (between p_H 7 and 8). It varies markedly, however, with small variations of p_H above p_H 8 and below p_H 7. The soly. of uric acid in Na acetate at different p_H values was also studied. The results were identical qualitatively and quantitatively with those obtained with Li acetate. It is not possible to attribute any particular solvent action to Li in contrast to Na. The soly. of uric acid in blood serum is equal to that noted in Li acetate, namely, 0.1 g.-equiv. per l. at a p_H and temp. equal to that of the serum. Since the concn. of Na in blood serum approaches 0.1 g.-equiv. per l. the influence of serum colloids on the soly. of uric acid is questioned. P. M.

The alkaloid content of galenic preparations of Lobelia inflata L. M. MASCRÉ AND M. CARON. *Bull. sci. pharmacol.* **37**, 657–61(1930); cf. *C. A.* **24**, 3083.—For the detn. of the alkaloids in the drug, mix 12.5 g. of the powder dried at 100° with 40 g. of 90% EtOH and 4 g. NH_4OH, some hrs. later add 360 g. Et_2O, filter after 4 hrs., take 360 cc. (4/5 of the total) and evap. to 10 cc. Dissolve in 150 cc. Et_2O, shake with 15 cc. *N* HCl, then 4 times with 5 cc. Evap. the Et_2O from the acid exts. at low temp., add 10 cc. of

silicotungstic acid (5%), filter after 12 hrs., wash with *N* HCl and incinerate. The wt. of the residue multiplied by 0.414 gives the wt. of the alkaloids. Com. drugs had an alkaloid content between 4.05 and 4.70%. For the analysis of tinctures, 100 g. is evapd. between 50° and 55° to 10 to 15 cc. After the addn. of 5cc. NH_4OH, ext. with Et_2O and proceed as before. The values in com. tinctures varied between 0.08 and 0.42%. The alkaloid content was rather const. within 6 months, also in solns. in water. Exts. had values from 0.55 to 1.70%. A. E. MEYER

The active principles of plants of the genus "Ryania" or "Patrisia" (Flacourtiaceae). P. LE COINTE. *Bol. esc. chim. ind.* (Belem) 1930, No. 1, 43–7; *Chimie & industrie* 24, 907.—The active principle of the root of *Ryania acuminata* was sepd. in a state of purity as follows: the finely powd. root is extd. with 50% alc. and the resin sepd.; addn. of neutral $Pb(OAc)_2$ to the liquid produces a Pb lake from which the coloring matter is removed by H_2SO_4, by neutralizing the H_2SO_4 with $BaCO_3$ the coloring matter is isolated as a dark-red powder; the filtrate from the Pb lake is concd., filtered, treated with H_2S, refiltered and treated with basic Pb acetate which produces a small quantity of light yellow ppt.: the washed ppt. on treating with H_2S yielded a liquid which, on evapn. *in vacuo*, yielded yellowish needles insol in Et_2O, benzine, $CHCl_3$ and Me_2CO; the filtrate from basic Pb acetate ppt. was treated with ammoniacal basic Pb acetate, yielding a heavy ppt.; treating the ppt. with H_2S, followed by filtration and evapn. *in vacuo*, gave an uncrystallizable, blackish brown, sirupy liquid; the filtrate from the last $Pb(OAc)_2$ ppt. was freed from excess Pb with H_2S, filtered and evapd. *in vacuo* over H_2SO_4, finally yielding a very hygroscopic mass of very fine colorless needles or small plates, which easily changed to a brownish sirup on exposure to the air. The crystals contain a glucoside, *ryanin*, which is the active principle; the brown sirup is *ryanetin*, a product of hydrolysis of ryanin. Ingestion *per os* by 7-kg. dogs of an aq. soln. contg. 10–20 cg. ryanetin (or 2 crystals of ryanin) produced congestion of the eyes, convulsions, accelerated breathing, paralysis of the lower limbs and finally death with tetanism after 30 min. ($1^1/_2$ hrs. with ryanin). Cf. following abstr. A. PAPINEAU-COUTURE

Chemical study of the glucosides of the root of Ryania acuminata. G. BRET. *Bol. esc. chim. ind.* (Belem) 1930, No. 1, 48–50; *Chimie & industrie* 24, 907.—B. considers that the glucosides are present in the roots of the plant as K and Ca salts. For their sepn. he used a slight modification of Le Cointe's technic (preceding abstr.): the filtrate from the neutral $Pb(OAc)_2$ ppt. is freed from Pb by H_2S, filtered, concd. *in vacuo* to sirupy consistency, and treated with abs. alc. to ppt. the glucosides in a pulverulent condition; after decantation of the supernatant liquid, the glucosides are dissolved in 50% alc., and converted into sulfates by adding H_2SO_4 till acid to litmus; the soln. is evapd. to dryness *in vacuo*, the mass is taken up in 50% alc., the metal sulfates are filtered out, and the filtrate is evapd. *in vacuo*. During evapn. glucoside A (Le Cointe's ryanin) crystallizes out, and evapn. to dryness *in vacuo* of the mother liquor gives glucoside B (Le Cointe's ryanetin). The free glucosides are liberated from the sulfates by treating with NH_4OH: glucoside *A* is cryst.; *B* is amorphous. One of them is possibly produced by hydrolysis of the other during the process of sepn. The sulfates of both glucosides are hydrolyzed by 1% HCl with production of glucose and an insol. resin. They are sol. in H_2O and dil. alc., insol. in abs. alc., very slightly sol. in Et_2O and benzine. Glucoside *B* is slightly sol. in $CHCl_3$. A. PAPINEAU-COUTURE

The fluorescence of aromatic substances. RENÉ ESCOURROU. *Chimie & industrie* 24, 779–84(1930); cf. Müller, *C. A.* 22, 4715.—The fluorescences (detd. by means of Wood's light) of a large no. of essential oils, tinctures, absolutes and synthetic perfumes, both pure and in alc. soln., are tabulated. The results confirm Müller that fluorescence is generally useless for detg. the purity of such substances. The fluorescence in alc. soln. is frequently quite different from that of the pure substance; more especially, pure citrus oils generally have but a very slight fluorescence, which, on addn. of small amts. of a solvent having an alc. OH, acquires a violet tinge, deepening and turning violet-blue on addn. of further amts. of the solvent. Addn. of compds. contg. a phenolic OH, of ketones, aldehydes or esters does not produce the violet fluorescence. Fractionation of oil of lemon with a large Robert column did not sep. the constituent producing the violet fluorescence in presence of alcoholic OH. Addn. of traces of certain substances in some cases materially alters the fluorescence. It is suggested that this might be used by mfrs. of essential oils who, by adding such substances to their products, would have a ready means of identifying their own products as compared with those of other mfrs. in case of dispute; it could also be useful in detecting the presence of small quantities of adulterants added to improve the aroma of lower grade products. A. P.-C.

Caryophyllene. L. N. NOGUIER. *Parfumerie moderne* 24, 685, 687(1930).—A brief review of its consts. and identification by production of caryophyllenic alc., caryo-

phyllene nitroside, caryophyllene nitrosate and caryophyllene nitrosochloride. A. PAPINEAU-COUTURE

The determination of nicotine by physical-chemical conductivity. G. A. PIGNET. *Mitt. Lebensm. Hyg.* **21**, 312–4(1930).—A nicotine soln. of about 0.001 *M* is titrated with 7–10% silicotungstic acid and the resistance plotted on squared paper. Since nicotine titrated alone with acid gives no break in the curve, 0.1 *N* HCl or H_2SO_4 is added as in the gravimetric detn., this giving a sharp pt. of inflection. F. L. S.-J.

Stabilization of gentian roots by alcohol vapors. CH. BÉGUIN. *J. pharm. chim.* [8], **12**, 49–63(1930). S. WALDBOTT

Influence of the pulping of fresh gentian root on the contained glucides. CH. BÉGUIN. *J. pharm. chim.* [8], **12**, 213–9(1930); cf. *C. A.* **24**, 5936. S. W.

A new color reaction for ephedrine. JOSEPH SIVADJIAN. *J pharm. chim.* [8], **12**, 266–9(1930); cf. Feng, *C. A.* **22**, 2017.—The reagent (*A*) is a mixt. of official H_2O_2 soln. and 4% NaCl. To 4 cc. of *A* in a test tube add a few mg. of ephedrine (*B*); if a salt of *B* is used, add 6 drops of 0.1 *N* NaOH. Heating for 1 min. in a boiling water bath produces a red color. On cooling, the color darkens, turning red-violet, which persists for several hrs. If NaCl is absent, *B* is split up, giving off an odor of BzH. The color test is not quite sp. for *B;* it is also given by the homologs of *B* (cf. Fourneau and Barrelet, *C. A* **24**, 352). For the test to be pos., the simultaneous presence in the mol. of 2 secondary functions, (CHOH) adjoining the nucleus, and ($NHCH_3$), seems essential. Aminoketones, primary alcs. or tertiary amines do not give the test. Strangely, pseudo-*B* the stereoisomer of *B*, and its homologs give an orange-yellow color with *A*. The latter is also a *test for pyramidone* (*C*) (cf. Charonnat and Delaby, *C. A.* **24**, 851): Warm *A* to about 90° and put in a crystal of *C;* with slight shaking, the liquid turns a beautiful blue which disappears after 5 min. S. WALDBOTT

The laudanum of Sydenham. F. PANCIER. *J. pharm. chim.* [8], **12**, 303–7(1930); cf. *C. A.* **7**, 1580, 2093.—The French Codex Supplement 1920 modified the 1908 formula for laudanum de Sydenham; as a result, the required 1% of morphine is more easily attained. In 6 out of 12 com. samples this was the case; in the other 6 (from 1 source) the percentage was low (0.695–0.725%). In all of them, the percentage of dry ext. (4.29–5.76%) was much lower than previously recorded results (6.925–8.673%; cf. *C. A.* **8**, 1846). P., in prepg. a laudanum from powd. opium contg. 11.04% morphine, found 7.93% ext. before the essences of cloves and cinnamon were added, and 10.52% afterward; the % of morphine changed from 0.975 to 0.942%. The possible causes of low ext. in the com. samples are discussed. S. WALDBOTT

Substitutes for morphine and codeine; dilaudid, dicodid, eucodal, acedicon. RENÉ HAZARD. *J. pharm. chim.* [8], **12**, 312–20(1930).—A résumé of the prepn., chem. structure, properties and therapeutic actions of dilaudid (*C. A.* **21**, 2934; **22**, 2984; **23**, 206), dicodid (*C. A.* **18**, 880; **21**, 962), eucodal (*C. A.* **13**, 3272; **15**, 1161) and acedicon (*C. A.* **23**, 3305, 3975). S. WALDBOTT

Biological experimental study of the lupine alkaloids. A. GUILLAUME. *Thesis*, Paris, **1930**; *J. pharm. chim.* [8], **12**, 335–6(1930); cf. *C. A.* **24**, 3811.—Reference is made to the basic work of Goris (*C. A.* **10**, 3093). In detg. alkaloids, the silicotungstic method is used. The migrations of alkaloids in the adult plant are studied under the influence of nutrition, light, climate, etc., also the migrations during germination of the grain and formation of plantules. The effect upon the alkaloids of drying the plant under different conditions is likewise considered. S. WALDBOTT

A report on the first stage in the French manufacture of silk threads ("crins de Florence") (for surgical ligatures). BRUÈRE. *J. pharm. chim.* [8], **12**, 345–9(1930).—An account is given of the manuf and different grades of this article. Italy and notably Spain (near Murcia) have been the European centers of the industry for which the eggs of the silk worms have heretofore been supplied by Southern France (cf. Ch. Secrétain, *Bull. soc. d'encouragement l'ind. nationale*, March **1928**, 216). S. WALDBOTT

Isotonic soap solution for injections. M. PICON. *J. pharm. chim.* [8], **12**, 481–4 (1930); cf. Netter, *et al.*, *C. A.* **21**, 1288.—Treat 100 g. ricinoleic acid prepd. by alcoholysis (Haller, *C. A.* **1**, 715) with 70 cc. of 10% alc. NaOH (which sats. half the acid). With gentle heating, a limpid, very slightly alk. liquid is obtained. Distil off the alc., heat on the water bath and dry at 100°. The product is completely sol. in water and even in 5% soln. is hardly alk. (p_H 7.7 to phenol red; alk. to litmus, acid to phenolphthalein). To prep. an isotonic soln., dissolve by gently heating Na ricinoleate 10 g., NaCl 7 g., H_2O sufficient to make 1000 cc. Filter through paper, fill into 10 cc. ampoules and sterilize for 30 min. at 120°. On cooling, the liquid is limpid, but becomes very slightly turbid afterward; re-warming will clear it again. This soln. is more stable and distinctly less alk. than aq. solns. of other soaps. S. WALDBOTT

Report on the functioning of the Control laboratory of Swedish pharmacies. A. RISING. *Schweiz. Apoth. Ztg.* **68**, 76–80, 90–2(1930); cf. *C. A.* **21**, 624. S. W.

Succus juniperi inspissatus. R. MAEDER. *Schweiz. Apoth. Ztg.* **68**, 126(1930).—The following mode of prepn. is superior to that of Pharm. Helv. IV: Stir crushed juniper berries (10 kg.) with 15 kg. hot H_2O; after 24 hrs. press off the residue. Again mix it with 15 kg. of hot H_2O and allow to stand 24 hrs., stirring occasionally. Press off the residue, strain the united juices and evap. to about 4 kg.; add 1.5 kg. sugar and 5 g. of solbrol (cf. *C. A.* **23**, 3516) to a total of 5.5 kg. Bring the sirup to a boil and skim it, then strain it through a moistened cloth. S. WALDBOTT

The new Supplement (V) to the German Pharmacopeia VI. J. BÜCHI. *Schweiz. Apoth. Ztg.* **68**, 313–7(1930); cf. *C. A.* **24**, 3320.—The new features of the supplement are pointed out, and frequent comparisons are made with the articles of Pharm. Helv. V. S. WALDBOTT

Composition of specialties and nostrums. E SCH. *Schweiz. Apoth. Ztg.* **68**, 529–31(1930); cf. *C. A.* **24**, 5111.—Results of the analyses of 32 prepns. examd. by different analysts are given. S. WALDBOTT

The deportment of monobrominated camphor in reference to compressed medicinal tablets. GEO. E. ÉWE. *J. Am. Pharm. Assoc.* **19**, 1307–8(1930).—At ordinary temps monobrominated camphor (*M*) volatilizes slowly; it volatilizes more rapidly as the temp. rises. In the manuf. of tablets serious losses of *M* may occur during granulation unless the temp. be controlled carefully. As high as 43% loss has occurred. On standing in the cold tablets may become encrusted with crystals of *M*. Such tablets after being brushed to remove the external *M* assayed about 98% of the original. Various batches of tablets were stored at room temp. for 1 yr. All showed crystals of *M* on the surface. Assays indicated losses of 3–9%. One sample in a partially filled container lost 9.8%. E. concludes that tablets of *M* should be stored in a cool place. L. E. WARREN

Synthetic drugs. I. G. FARBENIND. A.-G Fr. 680,146, Aug. 9, 1929. The H-ion concn. of diformaldehyde bisulfite compd. of arseno(1-phenyl-2,3-dimethyl-4-amino-5-pyrazolone) is reduced by neutralizing the aq. soln. by the addn. of salts having an alk. reaction such as Na_2SO_3, Na_2CO_3, Na phosphates and pptg. by adding alc. or ether.

Synthetic drugs. I G. FARBENIND. A.-G. (Hans Schmidt, inventor). Ger. 513,205, Oct. 7, 1927. See Brit. 298,234 (*C. A.* **23**, 2786).

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle and Hubert Oesterlin, inventors). Ger. 513,210, Feb. 22, 1929. Addn. to 510,451 (*C. A.* **25**, 1036). Hydroxyacylaminoaryl compds. of As and Sb are prepd. by substituting the OH group for NH_2 or halogen in compds. of the formula $Y.Ar.NHCO(CH_2)_nX$, where Y is a residue contg. ter- or quinque-valent As or Sb, *e. g.*, AsO_3H_2, Ar is an aryl residue, *n* is 1 or more and X is NH_2 or halogen. Thus, 4-chloroacetylaminobenzenearsonic acid (prepd. from *p*-aminophenylarsonic acid and $ClCH_2COCl$) may be boiled with aq. NaOH. Numerous other examples are given also.

Synthetic drugs. I. G. FARBENIND. A.-G. (Karl Streitwolf, Alfred Fehrle and Walter Herrmann, inventors). Ger. 513,026, Mar. 31, 1929. Addn. to 510,437 (*C. A.* **25**, 1035). Benzimidazolonestibinic acids are prepd. by treating *o*-diaminobenzenestibinic acids with the amt. of chloroformic ester required to react with one NH_2 group, and heating the urethans so obtained in mineral acid soln. An example is given. Cf. Ger. 511,738 (*C. A.* **25**, 1036).

Synthetic drug. LABORATORIUM REUMELLA ADOLF BOAS. Ger 511,093, Aug. 20, 1927 *α-Chloro-γ-iodo-β-propyl salicylate*, m. 57°, is prepd. by treating α,γ-dichloro-β-propyl salicylate with an alkali iodide in acetone soln. An example is given. The product is useful in treating rheumatism.

Synthetic drugs. SCHERING-KAHLBAUM A.-G. (Adolf Feldt, Walter Schoeller and Erich Borgwardt, inventors). Ger. 511,303, Dec. 13, 1925. The disodium salts of 4 ω sulfomethylamino 2-metalmercaptobenzenesulfonic acids are prepd. by the action of CH_2O bisulfite at a raised temp. on Na 4-amino-2-metalmercaptobenzenesulfonates Examples are given describing the prepn. of the auromercapto, argentomercapto and bismuthmercapto compds. Cf. *C. A.* **22**, 845; **25**, 1036

Synthetic drugs. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Hans G. Allardt, inventors) Ger. 511,467, Aug. 7, 1927. See Brit. 321,968 (*C. A.* **24**, 2836–7).

Synthetic drugs. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Hans G. Allardt, inventors). Ger. 512,723, Oct. 15, 1927. See Brit. 321,968 (*C. A.* **24**, 2836–7).

Cascara extracts. A. ROBERTSON and J. TAYLOR (TRONGATE), LTD. Brit. 335,115, Nov 25, 1929. The disagreeable flavor is removed from an aq. cascara ext. by the action of O, preferably produced in the ext. by adding a soln. of H_2O_2 and a reducing agent such as charcoal (preferably at a temp. of about 40°), followed by removal of the charcoal by filtration and addn., if desired, of glycerol and liquorice.

Calcium salts of organic acids. CHEMISCHE FABRIK MARIENFELDE G. M. B. H. Ger 511,947, Apr. 10, 1929. Ca salts of org. acids contained in vegetable and animal oils and fats, especially in cod-liver oil, are prepd. by sapong. the raw oil or fat with alkali and treating with $CaCl_2$ in the presence of finely divided substance such as steam to assist the pptn. of the Ca salts. The salts are used in *therapy*.

Amylcresol. JOSEPH MARSHALL (to Boot's Pure Drug Co., Ltd.). U. S. 1,789,410, Jan 20. In the production of a normal amylcresol, reaction is effected between a cresyl valerate and $AlCl_3$ and the resulting ketone is reduced (suitably by use of Zn and HCl). Cf. *C. A.* **24**, 5939.

Sterol derivatives. KNOLL AKT.-GES. CHEMISCHE FABRIK. Ger 514,095, July 24, 1927. Esters of sterols with oxygenated acids of P are prepd. by treating sterols with halogen compds. of P, directly or in an anhyd. solvent. Examples are given describing the prepn. of *monocholesteryl phosphate*, m. 195-6°; *dicholesteryl phosphate*, m. 186°; *cholesteryl phosphite*, m. 158°; and *sitosteryl phosphite*, m. 153°. The products are of pharmacol. value.

6,8-Diethoxyquinoline. FRITZ MIETZSCH and HEINRICH KLÖS (to Winthrop Chemical Co.). U. S. 1,790,066, Jan. 27. This compd., b_3 about 153° and m. 60°, an

intestinal remedy, is made by ethylating the 6,8-dihydroxyquinoline. The 6,8-dimethoxyquinoline is similarly produced.

Tertiary amines containing the 1-amino-2-hydroxypropyl residue. HEINRICH JENSCH (to Winthrop Chemical Co.). U. S. 1,790,096, Jan. 27. Tertiary amines of the general formula $H_2NCH_2CH(OH)CH_2N'XY$ wherein N′ represents nitrogen of a tert. amine, and X and Y stand for alkyl, aryl or carbon atoms belonging to a heterocyclic nitrogen-contg. nucleus, can be prepd. by causing sec. amines to act upon 3-halo-2-hydroxypropylamine salts (cf. Gabriel and Ohle, *C. A.* **12**, 688). Instead of using the 3-halo-2-hydroxypropylamine salts obtained by sapon. of 3-halo-2-hydroxypropylphthalimide it is also possible to cause the sec. amines to act upon 3-halo-2-hydroxypropylphthalimide (cf. Gabriel and Ohle, *C. A* **12**, 688) and then split off the phthalic acid residue. The new tert. amines are sepd. by means of an alkali and purified by distn. They are of *therapeutical value* and have a blood-sugar reducing action, being also useful as intermediate products for the manuf. of other medicines. 1-Amino-3-dimethylamino-2-propanol is a colorless, oily compd., b_{28} 103°, and forms salts readily sol. in water. 1-Amino-3-diethylamino-2-propanol, b_{80} about 115°. The product obtained from 3-chloro-2-hydroxypropylphthalimide and piperidine b_{22} 148–50°; and the product derived from 3-chloro-2-hydroxypropylphthalimide and monomethylaniline b_{20} 205–10°.

Glucosides. CHEMISCHE FABRIK VORMALS SANDOZ. Ger. 511,794, Mar. 17, 1927. Glucosides which act upon the heart are obtained by extg. an aq. mash of squills with org. solvents non-miscible with water in the presence of salts not readily sol. Thus, fresh squills are pulverized with water and NaH_2PO_4 and AcOEt. The mass is filtered, pressed and the residue further treated with AcOEt. The AcOEt layer of the filtrate contains the glucosides which are obtained by evapn. Other examples are given. Cf. *C. A.* **24**, 1469.

Glucoside from digitalis. CARL MANNICH Ger 514,096, Oct. 5, 1928. A new glucoside is prepd. by crystg from acetone, or from alc. of about 70% concn., that portion of the crude digitalis glucosides that is difficultly sol. both in $CHCl_3$ and also in alc up to 35% concn. (or in MeOH). An example is given. The product m. about 245° when rapidly heated, and is optically and physiologically active. Its formula is $C_{41}H_{66}O_{17}$. The new glucoside is best prepd. from the leaves of *Digitalis lanata*.

Vegetable lecithin. HERMANN BOLLMANN Ger. 511,851, Oct 22 1929 Vegetable lecithin is improved by the action of H_2O_2 on its aq emulsions. The H_2O_2 soln. is added to the emulsion of lecithin, oil and water and the whole is then dried.

Improving the odor of phenols. GEWERKSCHAFT MATHIAS STINNES. Ger. 514,341, Oct. 9, 1927. Crude or purified phenolic fractions for use as *disinfectants*, etc., are improved in odor by partial esterification, *e. g.*, with Ac_2O

Vitamin-containing products. AAGE W OWE. Norw. 44,018, Dec. 30, 1929. Vitamin-contg fats are saponified, preferably by means of slaked lime and the resulting product is extd. with an edible fat or oil Cf. *C. A.* **24**, 4901.

Heart-stimulant substances extracted from muscular tissue. I. G. FARBENIND. A.-G. Brit. 335,202, June 10, 1929. Muscular tissue is extd. with water-sol. org. solvents such as MeOH, EtOH or acetone, lipoids being removed by treating the tissue before extn. or by treating the ext. obtained with a water-insol. solvent such as ether or methylene chloride. Various details and modifications of procedure are described.

Purifying extracts containing sexual hormones. SCHERING KAHLBAUM A.-G. Ger. 511,116, Mar 16, 1929. The exts. are treated with Al amalgam. An example is given.

Hormones. I. G. FARBENIND. A.-G. Brit. 334,808 June 11, 1929. Hormones or active substances of the posterior lobe of the hypophysis are extd. and sepd. into those which act on the uterus and those which increase blood pressure. Various details of extn. and fractionation by successive pptn., etc., are given.

Antiseptics. GRAN. CHEM-PHARM. PRODUKTE G. M. B. H. and ERICH FREUND. Ger. 512,960, Apr. 21, 1928. An antiseptic $(CH_2)_6N_4CH_2(H_2PO_4)_2$, is prepd. by treating $(CH_2)_6N_4$ with an equimol. amt of $CH_2(H_2PO_4)_2$ in the presence of a solvent.

Intestinal disinfectants. CHINOSOLFAB. A.-G. Ger. 513,127, Jan. 31, 1928. Equimol. amts of 8-hydroxyquinoline, H_2SO_4 and $Al_2(SO_4)_3$ or $MgSO_4$ are caused to react. The reaction may be effected in an aq. medium or in the presence of org. solvents. Examples are given.

Disinfectants and bactericides. I. G. FARBENIND. A.-G. Fr. 690,820, Feb. 28, 1930. Products of the hydroxydi- or hydroxytri-arylmethane series contg. at least one univalent halophenol group are used as disinfectants and bactericides. Examples

are 2,2′-dihydroxy-5,5′-dichloro- and 2,2′-dihydroxy-3,5,3′,5′-tetrachlorodiphenylmethane.

Fumigant solution. HARRY W. HOUGHTON (to Safety Fumigant Co.). U. S. 1,790,095, Jan. 27. A soln. is formed for liberating a substantially permanent lethal and lachrymatory gas by evapn. on exposure in shallow layers and which comprises acetone and a carbohydrate such as glucose or glycerol together with HCN and CNCl.

Cleansing creams. GEORGES ROHFRITSCH and RODOLPHE LEUTZ. Fr. 691,635, Mar. 10, 1930. A cream for removing dirt from the hands without the use of water contains casein 9, lime water 16, NH_3 0.5, soda 1, oxycellulose or hydrocellulose 9, perfume 0.5 and water 64 parts.

Intermediates for perfumes and drugs. SCHERING-KAHLBAUM A.-G. (Hans Jordan, inventor). Ger. 511,464, Aug. 13, 1927. The condensation product from *m*-cresol and acetone described in Ger. 486,768 (*C. A.* **24**, 2256) is treated with Ac_2O in the presence of a small quantity of H_2SO_4. A new ketone $C_{24}H_{28}O_4$, m. 122–123°, is obtained, which loses one Ac group when sapond. with alc. KOH, yielding another new ketone $C_{22}H_{26}O_3$, m. 194–5°. An example is given.

Expanding tobacco by gas pressure and sudden release. WILFORD J HAWKINS (to American Machine & Foundry Co.). U. S. 1,789,435, Jan. 20. For increasing the vol of cured and conditioned tobacco, the material is permeated with air, CO_2, steam or other suitable gas under pressure, and the pressure is then suddenly released. App. is described. Flavoring substances may be added with the treating gas.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

The chamber process. XXII. Automatic nitric acid feeder to chamber system. Photoelectric method. MOTOTARŌ MATSUI AND TOKITI NODA. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 518-21(1930); cf. *C. A.* **25**, 560.—The relation between gas concn or gas pressure and photoelec. current proportional to intensity of light transmitted through the gas layer was investigated. Photoelec. current was detd. by deflection of a galvanometer having a sensitiveness of 4.7×10^{-10} amp. for a 1-m. scale. The whole circuit was insulated carefully by an equipotential shield (White, *C. A.* **9**, 3). The cell was of the K hydride type; the voltage applied, 150. A 5-megohm resistor was in the circuit for protection. An incandescent lamp was used as the light source. NO_2 was prepd. from pure $Pb(NO_3)_2$ purified by several redistns. and recrystns. Gas pressure was read by cathetometer. Dry air was introduced between Hg and NO_2. The gas temp. was 25 ± 0.1°. The sensitivity of the cell was checked after each detn. The *absorption spectrum of* NO_2 consists of a large no. of fine bands from 600$\mu\mu$ to 225$\mu\mu$; that of N_2O_4, of 2 continuous bands, one max at 340$\mu\mu$, the other max. further up in the ultra-violet. At 366$\mu\mu$ both NO_2 and N_2O_4 must have absorption bands. $E = d(p_{NO_2} + k_2/K(p_{N_2O_4})^2]$, where $K_p = (p_{NO_2})^2/p_{N_2O_4} = 0.1456$ at 25° (Bodenstein, *Z.* **16**, 1896), d = thickness of gas layer. Consts. k_1 and k_2 were found to be 5.99 and 53, resp. If mol. concn. is used instead of partial pressure, $k_1 = 1.47$ for NO_2, $k_2 = 62$ for N_2O_4. For white light from an incandescent lamp, $\log (I_0/I) = 5.85 d p_{NO_2}$; for $\lambda = 0.465\mu\mu$, $\log (I_0/I) = 5.92 d p_{NO_2}$. Very small concns. of NO_2 or N_2O_4 can be detd this way, and vacuum-tube amplification can control automatically the supply of NO_2 to the chamber system. E. M. SYMMES

By-product and synthetic ammonia. P. PARRISH. *Gas Eng.* **48**, 31-2, 36(1931); cf. *C. A.* **24**, 4375.—An economic discussion. E. H.

Potassium salts from insoluble minerals. G. CALCAGNI. *Ann chim. applicata* 20 522-7(1930).—By use of a technic similar to that used in the prepn. of sol. nitrosophosphates from insol. phosphates (cf. *C. A.* **24**, 459), *i. e.*, by bubbling N_2O_4 through a suspension of leucite [$K_2Al_2Si_4O_{12}$] in cold water, it was possible to bring into soln. up to 80% of the K_2O present. At the same time Al_2O_3 and SiO_2 may be recovered. Most of the N_2O_4 may be regenerated by igniting the nitrates formed. This method could not be applied to feldspars, as only traces of K_2O were brought into soln., even after prolonged treatment with N_2O_4. A. W. CONTIERI

The sulfates in industry, a review of the water-soluble products, sodium sulfate, ammonium sulfate and aluminum sulfate. CHARLES H. BUTCHER. *Chem. Trade J.* 87, 633-4(1930); **88**, 51-3(1931).—The forms in which these salts are found in com. use are noted and these uses mentioned. W. H. BOYNTON

Polymerization and solubility of phosphates. S. S. DRAGUNOV. *Zhur. Prikladnoi*

Khim. **3**, 797–805(1930).—A critical survey of the literature, with particular reference to $Ca(PO_3)_2$ which is as yet little investigated. Kahlbaum $Ca(H_2PO_4)_2.H_2O$ was heated for 1.5 hrs. at various temps. and rapidly cooled. Its soly in aqua regia (12 cc. HCl of d. 1.19 and 8 cc. HNO_3 of d. 1.42) was detd. by boiling 2 g. of the salt in 20 cc. of acid for 30 min. The soly. of the sample treated at 1020°, when fusion takes place, was detd. by shaking with distd water at 25°. After 68 days the soln. contained 2.3 g. P_2O_5 per 100 cc. (0.3 g. after 1 day; 0.4 after 2 days; 1.8 after 32 days). Mol. wt. could not be detd. This fused salt is a good *fertilizer*, but the high temp. at which it is obtained and the necessity of fusion are the difficulties which must be confronted in its manuf.

V. KALICHEVSKY

Preparation of potassium nitrate and alumina by double decomposition of potassium chloride and aluminum nitrate. I. The system $3KCl + Al(NO_3)_3 \rightleftharpoons 3KNO_3 + AlCl_3$. HIROMU TANAKA. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 488–92 (1930).—The solubilities of KCl and KNO_3 at various temps. are well known, but those of $AlCl_3$ and $Al(NO_3)_3$ are confusing. Redetn. showed great differences from Gerlach (Solubilities of Inorganic and Organic Compounds, Seidell (1919); cf. *C. A.* **14**, 380) and that soly. of $Al(NO_3)_3$ changes abnormally between 0° and 5°. Isothermal data at 10° and 0° of 4 ternary systems, each consisting of H_2O and 2 salts giving common ions by dissocn., are shown, as well as the quaternary system (K, Al)$(NO_3$, Cl$)$–H_2O at 10°. In prepn of KNO_3 by double decompn. of KCl and $Al(NO_3)_3$ the theoretical % utilization can be calcd. **II. Treatment of clay with nitric acid.** *Ibid* 493–5.—The soln. velocity of Al_2O_3, contained in clay, in HNO_3 is about the same as that in H_2SO_4 under the same conditions. The relation between the velocity consts. of soln of Al_2O_3 and temp. is expressed by the Arrhenius formula $T_1T_2/T_1-T_2 \log K_1/K_2 = 4460$ (approx.). Soln. velocity of Al_2O_3 is affected slightly by HNO_3 concn.

E. M. SYMMES

Reduction of sulfur dioxide. GEORGE J. YOUNG *Eng. Mining J.* **131**, 7(1931).—J. W. Beckman reduced SO_2 in the presence of a simple catalyst. A cylindrical chamber is heated by elec. means for maintaining the contact mass at 427–670°; SO_2 gas, mixed with natural gas or CO, is passed through a contact mass and discharges a gas from which elemental S condenses. The reactions are exothermic. Expts. have been confined to a lab. scale so far.

W. H. BOYNTON

Barite and barium products in 1929. R. M. SANTMYERS AND B. H. STODDARD Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 209–18(preprint No. 17 published January 7, 1931).

E. H.

A study of the properties of polyhalite pertaining to the extraction of potash. III. Calcination of polyhalite in a rotary kiln of laboratory size. LOYAL CLARKE, J. M. DAVIDSON AND H. H. STORCH. Bur. Mines, *Rept. of Investigations* **3061**, 12 pp.(1930). cf. *C. A.* **24**, 3198.—A 2 × 36 in. exptl. rotary kiln has been found satisfactory for the calcination of polyhalite sized between 28 and 150 mesh. Optimum conditions for the calcination and extn. treatments of 65–100 mesh material have been detd. Polyhalite extns. contg. up to 11.4 g. K_2SO_4 per 100 g. H_2O have been obtained with >95% extn Extns. of calcined 10–100 mesh polyhalite were inferior to those with the more finely ground material.

ALDEN H. EMERY

Enriching Khibinsk apatite by flotation. G. O. ERCHIKOVSKII. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 109–14(1930).—E found that with crude birch tar (1.3 kg. together with 0.3 kg of KOH per ton of apatite) more than 85% of apatite was extd. Good results were obtained by using 0.6 kg of birch tar, 0.15 kg. KOH and 0.24 kg. of water glass per ton. Expts. with oleic acid (0.7–0.13 kg. per ton of apatite) gave even better results than birch tar. Guaiacol, one of the compds. of birch tar, also gave very good results.

J. S. JOFFE

Nitrogen and its compounds. BERTRAND L. JOHNSON. Bur. Mines, *Information Circ.* **6385**, 33 pp.(1931).—Occurrence of N and its compds., the uses, mining and treatment of natural $NaNO_3$, fixation of atm. N, by-product N, world N industry, N industry in the U. S. and N industry in foreign countries are discussed. A 3 page bibliography is given.

ALDEN H. EMERY

The development of the Norwegian nitrogen industry and the reconstruction plans of the Norsk Hydro. AXEL AUBERT. *Teknisk Ukeblad* **75**, 218–21, 228–31(1928).—A review.

C. A. ROBAK

Sulfur and pyrites in 1929. ROBERT H. RIDGWAY. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 175–94(preprint No. 15 published December 18, 1930)

E. H.

Adsorptive properties of commercial lampblack. M. M. DUBININ AND S. A. TOROPOV. *Zhur. Prikladnoi Khim.* **3**, 843–55(1930).—Several grades of com. lampblack

were investigated. Ignition or activation with steam or with HNO_3 only partially cleans up the surface of the lampblack. Lampblack has a porous structure, with the pores of a size suitable for capillary condensation of org. solvents, *e. g.*, C_6H_6, PhMe. Methylene blue and I are well adsorbed from water solns. Adsorption of acids is very slight and of a complex nature. Successive treatment of lampblack with KOH and HCl cleans its surface rather thoroughly and yields a product which possesses normal adsorptive properties of an activated medium-grade carbon. V. KALICHEVSKY

Preparation and properties of an active alumina catalyst for industrial purposes. E. V. ALEKSEEVSKII AND I. G. PREIS. *Zhur. Prikladnoi Khim.* **3**, 859–62(1930); cf. *C. A.* **24**, 4442.—A dehydrating catalyst is prepd. by mixing 70% air-dried hydrated alumina, ground to pass a sieve contg. 900 openings per sq cm., with 30% kaolin from Glukhov, steaming the mixt. for 1 hr., adding enough H_2O to form a paste and forming hollow rings 12 mm. in diam. and 20 mm. high, which are dried for several hrs. at 150°. Hydrated Al_2O_3 is best prepd. by pptg. it with HCl from Na aluminate soln. or with NH_3 from $Al_2(SO_4)_3$ soln. The catalyst is used commercially for dehydrating EtOH. V. KALICHEVSKY

Preparation of an active platinum catalyst for industrial purposes. E. V. ALEKSEEVSKII AND I. D. MAKAROV. *Zhur. Prikladnoi Khim.* **3**, 857–8(1930); cf. *C. A.* **24**, 2246.—The method is similar to the one previously described. Kaolin-clay-charcoal rings were ignited for several hrs. at 950° and soaked in H_2PtCl_6 soln. so as to absorb 8% Pt by wt. of the rings. They were dried on a water bath and reduced at 120–150° with electrolytic H contg. HCHO vapors. V. KALICHEVSKY

Preparation of an active palladium catalyst for industrial purposes. E. V. ALEKSEEVSKII, A. P. MUSAKIN AND I. D. MAKAROV. *Zhur. Prikladnoi Khim.* **3**, 863–6(1930); cf. *C. A.* **24**, 2246.—Asbestos cloth soaked for 12–15 hrs. in a soln. of $PdCl_2$ in a 2*N* HCl soln. is dried on the water bath and reduced for 12 hrs. in an elec. furnace in an atm. of H satd. with moist HCHO, then cooled in the presence of H_2 and washed first with hot distd. water and then for 12 hrs. in cold water. Washing with water is highly important in activating the catalyst. Expts. show that the initial reaction velocity is always very slow, particularly if little Pd is deposited on the cloth. With 0.5% or less Pd by wt. the catalyst must be heated. The best results are obtained with 8% Pd, but in com. practice 2% Pd is the economic limit. Porous asbestos cloth should be used. V. K.

Adsorption phenomena on the surface of vanadium catalyst. I. E. ADADUROV. *Zhur. Prikladnoi Khim.* **3**, 833–42(1930); cf. *C. A.* **24**, 3610.—O is not adsorbed. SO_2 is adsorbed somewhat in proportion to the moisture content of the gases, reducing V from the quinque- to tervalent state. From the color of the catalyst, it is noted that this reducing action does not take place if the mixt. of SO_2 and air is properly contacted. By displacing adsorbed gases with N, SO_3 is chiefly obtained, which shows that SO_3 and not SO_2 is adsorbed during the reaction. As velocity of the gases through the catalyst does not influence the efficiency of contact, it is possible that the reaction takes place in the gaseous phase. The compn of the catalyst (SiO_2, SnO_2 and V_2O_5) also suggests that only O is activated, which is not adsorbed by the catalyst. V. KALICHEVSKY

Asbestos in 1929. OLIVER BOWLES AND B. H. STODDARD. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 195–207(preprint No. 16 published December 18, 1930) E. H.

Talc and soapstone in 1929. OLIVER BOWLES AND B. H. STODDARD. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 219–27(Preprint No. 18 published December 22, 1930) E. H.

The composition of commercial Ca arsenate (SMITH, MURRAY) **15.** Hydrocarbons (Ger. pat. 692,395) **10.** Device for the continuous drying of casein, etc. (Ger. pat. 511,543) **1.** Hardening water-glass cements (Ger. pat. 513,425) **4.**

British Chemicals and Their Manufacturers, 1931. London: Assoc. of British Chemical Manufacturers 405 pp.

Handbuch der Kali-Bergwerke, Salinen und Tiefbohrunternehmungen. Berlin: Verlag d. Kuxen-Zeitung. 688 pp. Linen, M. 40.

Kali-Kalender, 1931. Taschenbuch für Kalibergbau und Kali industrie. Edited C. HERMANN. Halle: Knapp. 186 pp. Linen, M. 5.20.

Hydrocyanic acid. I. G. FARBENIND. A.-G. (Walter Reppe, inventor). Ger.

511,517, Oct. 20, 1923. Addn. to 485,989 (*C. A.* **24**, 1185). In the prepn. of HCN by the methods of 485,989 and 510,407 (*C. A.* **25**, 1040), by heating $HCONH_2$ or $HCOONH_4$, or a mixt. of both, with indifferent gases over catalyzers, the temp. is kept above 250°. Examples are given.

Nitric acid. I. G. FARBENIND. A.-G. (Ernst Jänecke and Hermann Klippel, inventors). Ger. 512,639, July 2, 1929. Nitrous gases are enriched by passing them into a soln. of K_2SO_4, H_2SO_4 and HNO_3 and adding sufficient solid K_2SO_4 to ppt. the double salt $K_2HSO_4NO_3$, which is heated under reduced pressure to obtain the HNO_3 or N oxides directly.

Nitric acid. AMMONIAQUE SYNTHÉTIQUE ET DÉRIVÉS. (SOC. ANON.). Fr. 690,810, Feb. 28, 1930. HNO_3 is concd. in an app. in which the acid is preliminarily concd., and the steam from this concn. is used to denitrify H_2SO_4, and the acid is given a final concn. by the denitrified H_2SO_4. The heat of the HNO_3 vapors resulting from the initial concn. is used for concg. more HNO_3. Cf. *C. A.* **25**, 1041.

Concentrating nitric acid. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 46,338, April 8, 1929. The concn. is carried out under reduced pressure by means of boiling and dephlegmation without application of drying substances.

Phosphoric acid and alkali nitrates. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIM. (Pierre Jolibois and Georges Chaudron, inventors). Fr. 691,005, Mar. 3, 1930. An alkali chloride is reacted with $Pb(NO_3)_2$ to give an alkali nitrate and $PbCl_2$, which by the action of a natural phosphate dissolved or not in HCl is transformed into a Pb phosphate or chlorophosphate, and this is used to regenerate $Pb(NO_3)_2$.

Sulfonic acids. I. G. FARBENIND. A.-G. Ger. 514,080, Nov. 30, 1926. The products obtained by condensing $C_{10}H_8$ or its derivs. with olefins are sulfonated, alkylnaphthalenesulfonic acids being obtained. *The acids or their salts are useful as wetting or emulsifying agents.* Examples are given.

Sulfuric acid. LOUIS SIMPSON. Can. 308,293, Feb. 3, 1931. Dried and pulverized anhydrite is mixed with dried and pulverized oil yielding shale fines or pulverized retorted oil-yielding shale, and the mixt. is burned or calcined. The SO_2 is drawn off and converted into H_2SO_4 in a known manner. The clinker residue may be pulverized to make portland *cement*.

Sulfuric acid concentration. WM. C. MAST (to Chemical Construction Corp.) U. S. 1,790,507, Jan. 27. Acid is passed through a plurality of chambers in series, and a stream of hot gases is successively delivered to and released beneath the surfaces of the bodies of acid so as to pass upwardly through them in succession. App. is described.

Recovering and purifying dilute sulfuric acid from acid sludge. FRANKLIN E. KIMBALL. U. S. 1,790,049, Jan. 27. Acid sludge is treated with water to effect sepn. of oil, the oil is removed from the dil. acid, the latter is heated to above its atm. b. p. to effect further sepn. of oil and the dil. acid is removed from sepd. oil.

Sodium hydroxide and ammonia. ALFRED MENTZEL. Fr. 690,680, Feb. 26, 1930. $NaHCO_3$ is converted into NaCN by adding C and reacting on the mixt. with N at a high temp., and this is converted to NaOH and NH_3 by the action of steam at 400–500°.

Regenerating carbonated ammoniacal solutions. ALBERT GOSSELIN (to Soc. l'air liquide, Soc. anon. pour l'étude et l'exploitation des procédés Georges Claude). U. S. 1,790,303, Jan. 27. The soln. to be regenerated is circulated in "indirect contact" with and countercurrent to the regenerated soln., and the latter is heated by an external source of heat at the end of the regeneration and before return for countercurrent heat-exchange. App. is described.

Alkali metal cyanides. I. G. FARBENIND. A.-G. (Julius Drucker, Paul Lueg and Paul Weise, inventors). Ger. 512,700, Sept. 23, 1926. See Brit. 301,565 (*C. A.* **23**, 4304).

Alkali phosphates from iron phosphate. METALLGES. A.-G. (Freiherr Conway von Girsewald and Hans Weidmann, inventors). Ger. 514,246, May 18, 1929. The manuf. of alkali phosphate by the reaction of $FePO_4$ with an alkali carbonate soln. is effected under pressure, *e. g.*, in an autoclave at 200°.

Metallic cyanamides. NIKODEM CARO and ALBERT R. FRANK. (H. Heinrich Franck, inventor). Ger. 512,640, Feb. 9, 1929. See U. S. 1,745,753 (*C. A.* **24**, 1709).

Fluorides. WILHELM PIP. Fr. 691,419, Mar. 7, 1930. Double fluorides of Al and alkali are prepd. by mixing a soln. of an alkali fluoride, *e. g.*, NaF, with a soln. of AlF_3. The alkali fluoride is prepd. by the reaction of an alkali hydroxide or carbonate on H_2SiF_6, formed, *e. g.*, by the transformation of SiF_4 with water, or on an alkali silicofluoride with sepn. of the SiO_2 produced. The AlF_3 is obtained by treating compds. of Al such as

oxides, silicates or clay with H_2SiF_6, formed by the transformation of SiF_4 with water, or with a silicofluoride of Al.

Phosphates. Soc. d'études scientifiques et d'entreprises industrielles. Fr. 690,648, Feb. 25, 1930. $(NH_4)_2HPO_4$ is made by absorbing in boiling H_3PO_4 an amt. of NH_3 above one and below 2 mols. of NH_3 for 1 mol. of H_3PO_4, then in a 2nd operation at a temp. below about 60–70° causing the resulting liquor to absorb the remainder of NH_3 necessary to form $(NH_4)_2HPO_4$.

Soluble phosphates. Compagnie générale des superphosphates Pyrénéens (Soc. anon.). Fr. 691,748, Mar. 11, 1930. The sublimation products obtained from the treatment of phosphates, SiO_2 and C in an elec. furnace are used for making soluble further quantities of phosphates. The sublimation products may also be used for making soluble the residues from the furnace, which still contain phosphates.

Monophosphates of alkali and alkaline earth metals. Ingenuin Hechenbleikner (to Chemical Construction Corp.). U. S. 1,790,502, Jan. 27. A comminuted reagent such as phosphate rock or a Na salt is caused to react with dil. H_3PO_4, and the reaction products are subjected to spray desiccation to obtain a dry powd. monophosphate. Dust formed in the atomization of the material is scrubbed with part of the dil. H_3PO_4. App. is described.

Polysulfides. Ignaz Kreidl. Austrian 119,764, Mar. 15, 1928. Solid stable polysulfides for treating plants are prepd. by heating metal sulfides, oxides or other suitable compds. with S in the presence of a stable, non-drying dehydrating agent, *e. g.*, glycerol. To avoid evapn. or decompn. of the dehydrating agent, the reaction is effected at about 100° in the presence of a catalyst, *e. g.*, a sulfite or thiosulfate. Reference is made to the manuf. of polysulfides of the alk. earth metals, As, Cu and Pb. An example is given. Cf. *C. A.* **24**, 1178.

Removing soluble ferrocyanides from ammonium thiocyanate solution. Josef Schröter (Wilhelm Gluud, Konrad Keller and Walter Klempt, inventors). Ger. 511,575, Dec. 7, 1927. The NH_4CNS is heated to above 100°, with optional addn. of gaseous or aq. HCNS, and the ppt. so obtained filtered off. The method is applicable to crude NH_4CNS obtained in Fe vessels. The sol. $(NH_4)_4FeC_6N_6$ present is decompd. by heating into $H_4FeC_6N_6$ and NH_3, the former splitting up further into HCN and insol. polymerized ferrocyanide.

Metal carbonyls. I. G. Farbenind. A.-G Brit. 334,976, June 24, 1929; Fr. 691,993, Mar. 15, 1930. CO is caused to react with carbonyl-forming materials, which may be in solid form or in the presence of inert liquids or melts as described in Brit. 323,332 (*C. A.* **24**, 3329), in a plurality of sep. reaction vessels, through at least 2 of which either the gases or liquids contg. CO or the carbonyl-forming materials, or both, are at least in part passed in series. Various details of app and procedure are described. Cf. *C. A.* **24**, 5441.

Heavy metal azides. Jos. Meissner. Ger. 514,012, Sept. 26, 1929. Equiv. amts. of NaN_3 soln. and a heavy metal salt soln are fed continuously to a mixing chamber arranged at the top of a column fitted with baffles. The reaction products flow down the column, the purpose of which is to give the crysts. of pptd azide time to grow to the required size. A partial sepn. of crysts. and mother liquor is effected at the foot of the column.

Producing metal compounds with the aid of complex hydrofluoric acids. Albert F. Meyerhofer. Ger. 514,149, Dec. 21, 1923. A metal or its oxide, carbonate, etc., is treated with H_2SiF_6, the fluosilicate so obtained is converted into the desired compd. by double decompn. and the fluosilicate by-product is removed. H_2SiF_6 is regenerated by heating the fluosilicate to form a metal fluoride and SiF_4, by causing the metal fluoride to react with an oxide or carbonate and treating the fluoride then obtained with H_2SO_4 and SiF_4. The manuf. of $ZnCl_2$ by converting ZnO into $ZnSiF_6$ and decompg. this with NaCl is described by way of example, the Na_2SiF_6 also obtained being heated to give SiF_4 and NaF, which reacts with $CaCO_3$ to give CaF_2 and Na_2CO_3. H_2SiF_6 is regenerated from the CaF_2 and SiF_4. Other complex hydrofluoric acids may be used instead of H_2SiF_6. Cf. *C. A.* **24**, 5441.

Compounds of sexivalent chromium. Marvin J. Udy (to Electro Metallurgical Co. of Canada, Ltd.). Can. 308,128, Jan. 27, 1931. $CaCrO_4$ is made by roasting an intimate mixt. of finely ground ferrochrome, lime and alkali metal carbonate. The compd. is easily converted into other chromates or dichromates, or chromic acid or chromic anhydride.

Aluminum compounds. Trygve Greiff. Norw. 45,918, Dec. 31, 1928. The oxidic constituents of the raw material are passed into anhydrous F compds. The volatile F compds. are sepd. from the non-volatile compds., and the latter by treating

with NH_4Cl, are converted into chlorides including $AlCl_3$. The $AlCl_3$ is volatilized and can be decomposed into Al_2O_3 and HCl by treating with H_2O.

Pure alumina. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 45,196, May 29, 1928. Solns. of $Al(NO_3)_3$ or $AlCl_3$ are treated with sufficient CaO or $CaCO_3$ to ppt. Fe. This is filtered off, and Al_2O_3 is finally pptd. from the filtrate by further addn. of pure CaO or $CaCO_3$.

Ammonium and alkali sulfates. Kali-Forschungs-Anstalt G. m. b. H. Ger. 514,319, Nov. 12, 1924. This relates to the sepn. of alkali and ammonium sulfates from solns. contg. both. Alkali sulfate is caused to sep. by concg. the soln. at a high temp., at which the double alkali-ammonium sulfates are unstable, and this concn. is continued until $(NH_4)_2SO_4$ also begins to sep The sepd. alkali sulfate is removed, and the mother liquor is cooled. A double sulfate then seps., leaving a mother liquor satd in $(NH_4)_2SO_4$, this liquor being removed and concd. until alkali sulfate also begins to sep. with the $(NH_4)_2SO_4$. Further crystn. of the sulfates may be induced by addn. of alkali chloride and NH_4Cl at the appropriate stages. Modifications in the process are described, and detailed examples are given.

Ammonium nitrate in granular form. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 45,862, Dec. 3, 1928. The salt mass is moistened with concd. H_2SO_4 (in the place of H_3PO_4 as in Norw. 44,691) after which the moistened acid mass is treated with gaseous NH_3.

Ammonium nitrate and calcium carbonate. Odda Smelteverk Aktieselskap and Erling Johnson Fr. 690,757, Feb 27, 1930. A product contg NH_4NO_3 and $CaCO_3$ is made by treating a soln of $Ca(NO_3)_2$ with NH_3 and CO_2 and removing the water.

Ammonium phosphate and calcium nitrate. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 46,807 Aug. 19, 1929. Raw phosphate is converted to $Ca(NO_3)_2$ and NH_4 phosphate through the intermediary product $CaHPO_4$ by a combination of the following processes: partial reaction of the $CaHPO_4$ with $(NH_4)_2CO_3$, treatment of the residue consisting of $CaHPO_4$ and $CaCO_3$ with a quantity of HNO_3 sufficient only for the soln. of the carbonate, and further treatment of the remaining $CaHPO_4$ with $(NH_4)_2CO_3$.

Ammonium phosphate. Ingeniuin Hechenbleikner (to Chemical Construction Corp.) U. S. 1,790,503, Jan 27. Reaction is effected between NH_3 and dil. H_3PO_4 to produce a neutral phosphate soln., and the latter is subjected to spray desiccation to produce a powd. NH_4 phosphate, gases liberated in the spray drier being scrubbed with dil. H_3PO_4. An arrangement of app. is described.

Ammonium sulfate. Firma Carl Still. Ger 513,292, April 29, 1928 See Fr 673,994 (*C. A.* **24**, 2554).

Saturator and auxiliary plant for making ammonium sulfate. Eschweiler Bergwerks-Verein (Hans Hasenjager and Richard Middeldorf, inventors). Ger. 511,091, Jan. 12, 1927.

Barium salts. Sachtleben A.-G. für Bergbau und chem. Ind (Hans Volquartz, inventor). Ger. 513,462, Oct. 26, 1926 Sol. Ba salts are prepd. by the reaction of solid hydrated BaS with suitable dry NH_4 salts without applying heat. Thus, cryst. hydrated BaS and crys . NH_4Cl may be shaken together without heating; whereupon the mixt. liquefies and cools to —20°, with sepn. of $BaCl_2.2H_2O$

Production of carbon monoxide and phosphorus pentoxide or phosphoric acid. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Norw. 45,994, Jan. 21, 1929 Phosphorus is oxidized according to Norw. 45,018 A quantity of air is introduced together with CO_2 in such proportions as to produce a H-N ratio of 3:1 when the gas, after sepn. from P_2O_5, is made to react with H_2O.

Solid carbon dioxide. Hermann Hamburger and Hugo Hamburger Austrian 119,947, June 15, 1930. CO_2 is liquefied, and the liquid is further cooled in molds until it has crystd.

Utilizing solid carbon dioxide. Franz Lejeune. Austrian 119,944, June 15, 1930. The solid is rendered available for use in *satg. benzine* or *prepg. beverages* by introducing it into containers of such a size that the gasified CO_2 exerts a pressure of about 2 atm. A suitable container and a charging device are described.

Carbon disulfide, etc. H. Oehme and Chemische Fabrik Kalk Ges. Brit. 334,856, Oct. 2, 1928. In the process described in Brit. 314,060 (*C. A.* **24**, 1187) for the manuf. of CS_2 from H_2S, the mixt. of H_2S and H obtained after removing the CS_2 from the mixt. coming from the reaction chamber is returned to the original crude gas instead of being treated for the extn. of H_2S, or the H_2S may be removed from the mixt. and used for producing elemental S, salts contg. S or S compds. other than CS_2. Instead of using

ammoniacal NH_4 sulfide soln. for absorbing the H_2S, alkali or alk. carbonate solns. or adsorbent materials of large superficial area may be employed.

Compounds of hydrogen peroxide. I. G. FARBENIND. A.-G. Fr. 692,026, Mar. 17, 1930. Compds. of H_2O_2 with solid substances are made by the reaction of the solid substances with gaseous H_2O_2 dild. by other gases. Thus a mixt. of H with 3% of O and 4 7 g. of H_2O_2 per cu. m. obtained by elec. discharge is passed through a layer of dry cryst. urea cooled by ice water. A product contg. 33.3% of H_2O_2 is obtained. With anhyd. Na_2SO_4 a product contg. 6.26% of H_2O_2 is obtained.

Iodine monochloride. SCHERING-KAHLBAUM A.-G. Ger. 512,563, Feb. 22, 1930. Solns of ICl are prepd. by the action of Cl on a suspension of I in equimol. proportions. I compds. in which the I is liberated by Cl, *e. g.*, KI, may be substituted for the I. Thus, a current of Cl is led into a suspension of I or KI in concd. HCl.

Lead phosphate. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIM (P. Jolibois and G. Chaudron, inventors). Fr. 690,744, Feb. 27, 1930. A Pb phosphate or chlorophosphate is made by grinding natural phosphate, treating it with HCl, adding a Pb salt such as $PbCl_2$, litharge or $PbCO_3$ and sepg. the ppt. A salt corresponding to the formula $PbCl_2.3(P_2O_5.3PbO)$ is obtained.

Phosphoric acid and phosphates. SOC. D'ÉTUDES POUR LA FABRICATION ET L'EMPLOI DES ENGRAIS CHIM. (P. Jolibois and G. Chaudron, inventors). Fr. 690,818, Feb. 28, 1930. H_3PO_4 is obtained in a form directly usable by the reaction of a Pb phosphate, such as $P_2O_5.3PbO$ or the $PbCl_2.3(P_2O_5.3PbO)$ described in Fr. 690,744 (preceding abstr.), with an acid which forms an insol. Pb salt. If a salt such as $(NH_4)_2CO_3$ is used, a phosphate is obtained.

Concentrating solutions of magnesium chloride. SHELDON B. HEATH (to Dow Chemical Co.). U. S. 1,789,385, Jan. 20. The soln. is evapd. by heating it by means of a Ni heating surface such as heating coils of Ni tubing while maintaining the soln. and Ni in contact with a body of Al, which serves to prevent corrosion of the Ni.

Nitrogen oxides. FREDRIK W. DE JAHN (to Frank A. Bower). U. S 1,789,580, Jan 20. Various details are described of an app. for producing N oxides from an NH_3-air mixt., including a pre-heater, oxidizing app., coils within the latter for reducing the temp of the N oxides immediately after their formation, and connections for utilizing the N oxides as a heating medium in the pre-heater.

Potassium nitrate. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Norw. 45,861, Dec. 3, 1928. KCl and H_3PO_4 react to form K_3PO_4 and HCl, the latter is removed by heating, and K_3PO_4 is treated with hot HNO_3. The soln. is then cooled until the KNO_3 ppts.

Potassium and ammonium phosphates. I. G. FARBENIND. A.-G. (Kurt Röhre and Robert Griessbach, inventors.) Ger. 513,267, Feb. 6, 1927. In order to sep. phosphates of K and NH_4 from solns. contg. both, the soln. is treated with H_3PO_4, or with NH_3 or alkali, in the amt. required to form the dipotassium and diammonium salts. After concg. and cooling, $(NH_4)_2HPO_4$ seps. out. The residual soln. is then treated with H_3PO_4 in the amt. required to form the monopotassium and monoammonium salts and is further concd. if desired. KH_2PO_4 then seps. out. An example is given.

Recovering potassium salts used in treating phosphates. CHEMIEVERFAHREN G. M. B. H. Ger. 511,214, Nov. 29, 1928. In opening up crude phosphates by treatment with K_2SO_4 and an acid, *e. g.*, HNO_3, the sepd. $CaSO_4$ carries with it some K_2SO_4 in the form of a double salt. To recover the K_2SO_4, the $CaSO_4$ is washed twice with water acidified with HNO_3 and is stirred between the washings. The second wash liquor may be used in treating a fresh batch of phosphate.

Treating potassium feldspar and other potash-containing silicates. A. KVALHEIM. Norw. 42,628, Dec. 10, 1928. The silicates are treated with Cl in the presence of C at suitable temp. The chlorides formed are sepd. by aid of the difference in their b. ps. The $SiCl_4$ is electrolyzed to form Si and Cl.

Recovery of sodium carbonate from natural alkaline waters or brines. JAMES G. MILLER and ALEXIS C. HOUGHTON. Can. 308,001, Jan. 27, 1931. Brines contg. Na_2CO_3 and dissolved silica are treated with sufficient caustic alkali to prevent the sepn. of silica and chilled to approx. 5° to ppt. $Na_2CO_3.10H_2O$. Cf. *C. A.* **24**, 3613.

Furnace for making sodium sulfate, etc. FRIEDRICH BÖHM. Ger. 511,463, May 4, 1927. A method is described of securing the scrapers, not involving the use of screws.

Reducing sulfur dioxide. MAITLAND C. BOSWELL. Can. 308,238, Feb. 3, 1931. A catalyst is prepd. by the action on an oxide of a metal of the Fe group of SO_2 and H to cause the oxide to take up S and form a porous mass. SO_2 and H are passed through the mass in the proportions of 1 to 2 at 300° to reduce the SO_2. Cf. *C. A.* **24**, 4126.

Sulfur trioxide from sulfur dioxide. CYRIL B. CLARK (to General Chemical Co.). U. S. 1,789,460, Jan. 20. In a process involving the catalytic oxidation of SO_2 to SO_3 in stages, a portion of the hot, partially converted gas is removed from the conversion system and cooled to below the temp. suitable for further conversion, and the cooled portion is introduced into the hot gas of the system to regulate its temp. An arrangement of app. is described Cf. *C. A.* **24**, 1474.

Sulfur trioxide. S. ROBSON and P. S. LEWIS. Brit. 334,862, June 8, 1929. A catalyst for oxidation of SO_2 is prepd. by mixing a V compd. which will react with SO_2 to yield vanadyl sulfate with an inert carrier such as pumice, kieselguhr, diatomaceous earth or pptd. silicic acid, and treating while cold with an acid gas such as SO_2 until the product gives an acid reaction to litmus and gas is no longer absorbed (the temp. is maintained sufficiently low to avoid substantial removal of water present). Catalyst promoters such as salts of Sn, Bi or Mn may be added. The catalyst thus formed is immune to poisons and converts 94–95% of SO_2 to SO_3 when used at 400°.

Filtering titanium sulfate solutions. I. G. FARBENIND. A.-G. (Paul Weise and Friedrich Raspe, inventors.) Ger. 513,291, July 23, 1929. The filtration of crude acid solns. of $Ti(SO_4)_2$, obtained from Ti ores and H_2SO_4, is readily effected by reducing the soln. so that some of the Ti is present in the tervalent state, cooling to below 35°, and filtering through nitrated filter cloth. Cf. *C. A.* **24**, 696.

Zinc chloride purification. JESSE O. BETTERTON (to American Smelting and Refining Co.). U. S. 1,789,299, Jan. 20. $ZnCl_2$ contg. impurities such as Pb, Pb chloride and Pb oxychloride is melted with an excess of metallic Zn, and portions of the molten salt material are recirculated through the adjacent metal in the container; a slag of purified $ZnCl_2$ is allowed to form on the surface of the bath and is removed. Cf. *C. A.* **24**, 1710.

Zinc oxide. ORKLA GRUBE-AKTIEBOLAG. Norw. 45,612, Dec. 31, 1928. $ZnCl_2$ solns. contg $MgCl_2$ are treated with CaO in amts. less than that required to convert the Zn content into $Zn(OH)_2$. The oxychlorides of Zn obtained, after being completely or partially sepd. from the mother liquor, are treated at a higher temp. (70° or more) with CaO in amts not exceeding that required to convert them into ZnO or $Zn(OH)_2$ A minor content of Cl should be retained in the resulting ZnO.

Zinc sulfide. ST. JOSEPH LEAD CO. Fr. 691,826, Mar. 12, 1930. See Can. 306,140 (*C. A.* **25**, 782).

Zirconium oxychloride. KALI-CHEMIE A.-G. (Friedrich Rüsberg and Paul Schmid, inventor). Ger. 512,402, Jan. 4, 1927. Addn. to 510,574 (*C. A.* **25**, 1044). In the production of $ZrOCl_2$ by the method of 510,574, *i. e.*, treating a fused product of ZrO_2, CaO, SiO_2 and $Fe_2O_3 + Al_2O_3$ with HCl and $CaCl_2$, a smaller quantity of HCl than is necessary to produce $ZrOCl_2$ and neutral $CaCl_2$ is used for dissolving the mass, and further HCl added after the sepn. of the insol. constituents and before the production of $ZrOCl_2$ by crystn.

Active carbon. I. G. FARBENIND. A.-G. Ger. 512,798, Nov. 6, 1923. Addn. to 461,884. Wood, cork, etc., in granular form is heated to glowing with alkali compds (*e. g.*, KOH) and K_2S or K polysulfide, and optionally K_2CO_3, to form a highly active decolorizing C. Cf. *C. A.* **25**, 1045

Carbon of low electrical resistance. CARLETON B. EDWARDS and HAROLD R. HORNER (to Peter C Reilly). U. S. 1,789,380, Jan. 20. In prepg. a carbon suitable for electrode manuf., pitch coke is fed into the upper end of a vertical retort having a relatively small cross-sectional area. At a lower portion of the retort the coke is subjected to a temp. of about 1790°, and at this portion of the retort air is drawn through its walls and passed upwardly through the descending charge of coke; the carbon produced is gradually withdrawn from the lower end of the retort. App is described.

Adsorbent comprising carbon, iron and iron oxide. CHRISTIANUS J. G. AARTS. U. S. 1,789,507, Jan. 20 Finely divided Fe oxide is distributed over a voluminous carbonaceous carrier, such as wood wool, filling substantially an entire reaction space, and a gas contg. CO is passed through the material at a temp. (suitably about 350–450°) at which the Fe oxide is reduced for the most part but not entirely. The product is suitable for *decolorizing sugar juices*, etc., or for use as a *pigment* or *carburizing agent* or for *electrode manuf.* Cf. *C. A.* **24**, 2256.

Absorption agents. MAXIMINE (SOC. ANON.). Fr. 690,684, Feb. 26, 1930. Porous products having a basis of active charcoal are made by incorporating a carrier such as finely divided wood pulp with active charcoal, expelling excess water, compressing to the desired shape and drying.

Hydrogen. MARIA CASALE-SACCHI. Austrian 119,928, June 15, 1930. In the manuf of H by reacting CO with steam and sepg. the mixt. of H and CO_2 so obtained,

the CO_2 is led with O through glowing coke to regenerate CO, which is freed from SO_2 (derived from the coke) and used again.

Hydrogen from steam and carbon monoxide. JOHN S. BEEKLEY (to duPont Ammonia Corp.). U. S. 1,789,538, Jan. 20. A Cr oxide catalyst is employed which is preliminarily heated in a non-oxidizing atm. to about the reaction temp. Cf. *C. A.* **24**, 3331.

Hydrogen producer. BAMAG-MEGUIN A.-G. Ger. 491,789, Feb. 23, 1928. Details are given of a periodically operated steam-Fe H producer with an overhead heating chamber. Cf. *C. A.* **24**, 1945, 4596.

Production of a mixture of nitrogen and hydrogen in proportions suitable for ammonia synthesis. EMIL EDWIN. Norw. 39,562, Dec 30, 1929. A gas mixt. consisting chiefly of CO and H_2, with possibly some N_2 and CO_2 or H_2O, is produced by reaction of gaseous, solid or liquid carbonaceous materials with H_2O in an elec. high-voltage arc or flame. The heat of the gas is utilized in carrying out such gas reactions with air, steam or atomized water as will produce a gas mixt. consisting chiefly of N_2 and H_2 in the desired proportions, from which the constituents other than H_2 and N_2 are afterward removed.

Phosphorus. VICTOR CHEMICAL WORKS. Fr. 691,872, Mar. 13, 1930. P is obtained by making briquets of a mixt. of ore contg. P and carbonaceous material for the reduction and a siliceous material, though it is preferred to add the siliceous material separately to the furnace. The briquets are heated in a furnace, and the P is liberated and volatilized.

Phosphorus. VICTOR CHEMICAL WORKS. Fr. 692,296, Mar. 19, 1930. Briquets contg. a P ore, a reducing agent such as a carbonaceous material with or without a siliceous material have incorporated therewith the "fumes" coming from the gases escaping from the plant for the volatilization of the P.

Apparatus for melting sulfur. EVERETT E. BRAGG (to General Chemical Co.). Can. 308,133, Jan. 27, 1931. Structural features.

Hydrogenation catalysts. E. I. DU PONT DE NEMOURS & Co Fr. 691,913, June 6, 1929 A catalyst for hydrogenation, dehydrogenation and the synthesis of org. compds. is composed of a difficultly reducible basic oxide and a difficultly reducible acid oxide, the latter being in excess of that necessary to give a neutral catalyst. A catalyst with which a practically pure MeOH is obtained from H and CO may be prepd. by gently heating a basic chromate of Zn and NH_4. Small quantities of alkali metal compds. *e. g.*, 0.25–5%, may be incorporated with the catalysts for the production of compds. of higher mol. wt. such as higher alcs., ketones, esters and aldehydes. Cf. *C. A.* **24**, 1649.

Sulfonated aliphatic compounds. H. TH. BÖHME A.-G. Fr. 691,976, Mar. 15, 1930. Sulfonated fatty acids and esters, free from unsulfonated elements, are obtained by treating sulfonated oils after neutralization with hydrocarbons or other appropriate solvents and sepg. them from the layer of solvent. The products are *used as wetting, purifying, emulsifying and impregnating agents.*

Urea and products containing urea from calcium cyanamide. E. JOHNSON. Norw. 45,319, July 9, 1928. $CaCN_2$ is decomposed by water, and the soln. of H_2CN_2 is hydrolyzed with formation of urea. During the hydrolysis the soln. is concd. *in vacuo* with application of heat.

Plastic masses. ALFRED ROGLER. Fr. 691,875, Mar. 13, 1930. From 5 to 30% of oil-sol acids such as cinnamic, phthalic, salicylic or lactic acid and a basic metallic compd. sufficient for neutralization (*e g.*, Ti white, white lead, MgO or lithopone) are added to vegetable oils such as linseed, wood, poppy or castor oil and the mixt. heated until a uniform plastic mass of the desired consistency is obtained.

Plastic materials. WALTER HENGSTMANN. Fr. 691,728, Mar. 11, 1930. A plastic material is composed of a mixt. of a cellulose ether, natural or artificial resin and an ester of a dibasic acid of the aliphatic series. Thus, ethylcellulose is dissolved in a mixt. of benzene, ethylacetate and acetone, the soln. is mixed with a soln. of resin in benzene and a small quantity of adipic acid is added. The mixt. is pressed into blocks or plates under high pressure at about 60° and allowed to dry. S or compds. liberating S may be added to the mixt. which is then vulcanized during molding by heating to 150°.

Condensation products soluble in water. I. G. FARBENIND. A.-G. Fr. 690,688, Feb. 26 1930. Condensation products which are sol. in water are prepd. by treating at a moderate temp. under vacuum the condensation products obtained under moderate conditions from CH_2O and aliphatic aldehydes or ketones or mixts. thereof. Examples are given.

Condensation product of urea with formaldehyde. OSCAR A. CHERRY (to Economy Fuse and Mfg. Co.) U. S. 1,790,461, Jan. 27. Urea and CH_2O are condensed at a H-ion concn. of about 1×10^{-3}, free water is distd. from the condensation product at a H-ion concn. of about 1×10^{-7} and the condensation product is converted into a final product at a H-ion concn. of from 1×10^{-5} to 1×10^{-3}. Numerous details of procedure are described. Cf. *C. A.* **24**, 930.

Condensation products. I. G. FARBENIND. A.-G. (Carl Müller v. Blumencron and Ernst Hochheim, inventors). Ger. 511,979, Jan. 13, 1926. Addn. to 510,513 (*C. A.* **25**, 1045). Urea-CH_2O condensation products are hardened by acids instead of the SO_2 of 510,513. Volatile acids are preferred. The examples mention H_3PO_4, HCOOH, HBr, HCl, H_2SO_4 and HF.

Adhesive. I. G. FARBENIND. A.-G. (Erich Richter, inventor). Ger. 511,297, Aug. 21, 1928. An adhesive for securing mouthpieces to cigaret paper comprises an org. solvent soln. of a cellulose deriv., a softener and a resin. Examples are given.

Adhesive. OTTON GENACHOW. Austrian 119,948, June 15, 1930. An adhesive for securing metal foil, etc., to wood, paper, etc., comprises albumin, NH_4Cl, and glycol, erythritol or other polyhydric alc. No proportions are specified. After applying the adhesive, the materials to be united are heated in a hydraulic press to 120° and allowed to cool before the pressure is released.

Preserving adhesives such as starch paste. I. G. FARBENIND. A.-G. Brit. 334,876, May 1, 1929. Adhesives are preserved by addn. of a small proportion of a hydroxydiarylmethane or hydroxytriarylmethane contg. 1 or more halophenol radicals such as methylenebis-2,4-dichlorophenol or similar compds. (various examples of which are given).

Vegetable glue. ELLERY H. HARVEY (to Perkins Glue Co.). U. S. 1,790,346, Jan. 27. A glue suitable for use, without dilu., for general furniture veneering is formed by dissolving starch such as cassava starch of a "specific viscosity less than 60,000" in about 3 times its quantity of water in the presence of a sufficient quantity of an Fe compd. such as $FeSO_4$ for increasing the viscosity to form a fluent glue with a "specific viscosity of at least about 80,000."

Barite. BARYT G. M B. H. Ger. 512,546, Jan. 23, 1925. Crude heavy spar is worked up by calcining, slaking and suspending in water. The heavy spar collects at the bottom of the vessel, and the principal impurity, Ca, can be poured off as milk of lime. The heavy spar can then be further refined by treating with a small quantity of HCl.

Crystallizing constituents from brines. RUSSELL W. MUMFORD (to American Potash & Chemical Corp.). U. S. 1,790,436, Jan. 27. In cooling a brine such as Searles Lake brine contg. constituents, two of which such as borax and KCl have solubilities decreasing on cooling and one of which is capable of a higher degree of supersatn. than the other, the brine is subjected to an initial stage of evaporative cooling to reduce the temp. to nearly the satn. point with respect to the constituent such as borax capable of a higher degree of supersatn., while pptg. the other constituents, and the brine is then subjected to rapid cooling while further pptg. the latter and maintaining the other constituent in a state of supersatn. Cf. *C. A.* **24**, 209, 928.

Synthetic gems. WIEDE'S CARBIDWERK FREYUNG M. B. H. Ger. 511,945, Aug. 15, 1928. Spinel with a morganite-like pink color is formed by the crystn. of an Al_2O_3 and Mg mixt. to which Fe, Be and Ti (or their compds) are added, after fusing in a crucible. In the example, 0.2 g. TiF_4, 0.5 g. BeO and 10 g. Fe_2O_3 are fused with 500 g Al_2O_3 and 100 g. Mg powder.

Synthetic materials. I. G. FARBENIND. A.-G. Fr. 691,901, Mar. 14, 1930. The crude polymerization products of butadiene hydrocarbons or their transformation products or their preliminary products are sepd into fractions by means of solvents. These fractions may be mixed with natural rubber or fractions thereof. An example is given in which the first fraction is suitable for the manuf. of *artificial silk*, and the second for *coatings* or for *impregnating paper*. Other examples are given in which fractions suitable for vulcanization to *synthetic rubber* are obtained.

Effecting reactions such as those between phosphate rock and sulfuric acid. OTTO BALZ and WILHELM WAGNER (to I. G. Farbenind. A.-G.). U. S. 1,790,220, Jan. 27. A small quantity of metaphosphoric acid (suitably about 0.3–10% the quantity of phosphate rock) is added to facilitate the sepn. of $CaSO_4$ formed.

Treating gypsum for cement and sulfuric acid production. FRITZ ROTHE and HANS BRENEK (to Rhenania Verein chemischer Fabriken A.-G.). U. S. 1,790,023, Jan. 27. A mixt. of gypsum and silica is heated in an oxidizing atm. to above 1100° by use of heating gases contg. at least 15% by vol. of steam.

Furnace for calcining gypsum. ANDRÉ BOURDET. Ger. 514,068, Feb. 6, 1930.

The gypsum is passed through 2 heated tubes, the first being the hotter. Hot gases pass in the same direction as the gypsum in the first tube, and countercurrent to the gypsum in the second tube.

Purifying pyrites-burner gases. I. G. FARBENIND. A.-G. (Franz Vorländer, inventor). Ger. 514,318, May 21, 1925. In purifying pyrites-burner gases by an acid wash followed by filtration or elec. cleaning, the washing acid used is of such concn. that it boils above 100° and slightly above the temp. of the gases supplied to the washer. Thus, the gases may be cooled to 125° and washed with H_2SO_4 of 45° Bé. Better results in the final purification are then obtained.

Apparatus for cleaning, classifying and grading materials such as asbestos. ROGER Q. KYLE. U. S. 1,790,429, Jan. 27. Structural and mech. features.

Bleaching. CHEMISCHE FABRIK VON HEYDEN A.-G. (Max Kahlert, inventor). Ger. 512,863, Nov. 24, 1925. A bleaching lye of metal hydroxide or oxide soln. or suspension, and gaseous Cl, is prepd. by satg. the liquid with Cl mixed with indifferent gas (*e. g.*, air) by allowing the gas to flow up a tower, down which the liquid is allowed to trickle.

Clarifying agent. MAXIMINE (SOC. ANON.). Fr. 690,992, Mar. 3, 1930. A clarifying agent is made by peptizing carbonized org. substances by grinding them in the moist state with appropriate colloids. The colloids used are chosen to suit the purpose to which the clarifying agent is to be put. Thus, albumin is used for the sugar industry and gelatin for wine making. The process allows active charcoals in paste form to be dried without passing to the non-reversible gel state.

Waterproofing compositions. E. I. DU PONT DE NEMOURS & CO. Fr. 691,915, July 8, 1929. See Brit. 315,228 (*C. A.* **24**, 1742).

Treating plants. J. SEIBT & BECKER. Ger. 511,066, May 4, 1929. Bleached and (or) dyed parts of plants, fresh or dried, are impregnated with an aq. soln. of a fatty acid salt, *e. g.*, a potassium soap, to which glycerol or other hygroscopic substance may be added. The treatment preserves the appearance of the fresh parts and imparts a fresh appearance to dried parts

Iodide and iodide-starch paper. VIKTOR BAUSCH and FELIX SCHOELLER & BAUSCH. Ger. 511,164, Dec. 2, 1927, and 511,165, Jan. 19, 1928, addn. to 511,164. Iodide or iodide-starch paper for use in telegraphy includes a reducing agent in small quantity, *e. g.*, rongalite 1 to KI 100 g., to prevent sepn. of I when the paper is stored. The starch used may be crude insol. starch, with or without sol. starch (511,164). The stability of the paper can be further improved by adding an alk. substance, *e. g.*, $NaHCO_3$, as well as a reducing agent (511,165). Cf. *C. A.* **25**, 1048.

Strip metal matrices for production of ribbon sound records. H. WATSON and J. GOOD. Brit. 335,181, June 17, 1929. Various mech. details of manuf. are described.

Gramophone disks. CHEMIE & TECHNIK J. M. S. GES. and H. MENZ. Brit. 335,219, June 19, 1929. A compn. is used composed of old gramophone disk material contg. shellac and vulcanite, and waste material of the character described in Brit. 335,194 (*C. A.* **25**, 1401), the old disks being ground, mixed with the waste compn. and boiled in bone oil with the addn. of spirit.

Materials for diaphragms of loud-speakers, telephones, microphones, etc. H. VOGT. Brit. 335,248, Oct 4, 1928. A vibratable diaphragm is placed face to face with a condenser plate or between 2 condenser plates from which it is insulated by a nitrocellulose varnish or the like contg. a more conductive pulverulent material such as slate powder or Pb oxide. Cf. *C. A.* **25**, 1049.

Heat-conducting mixture for bending metal blocks, etc. FULLER LEHIGH CO. and BABCOCK & WILCOX, LTD. Brit. 335,086, Oct. 15, 1929 A mixt. suitable for bending metal blocks, tiles, linings, etc., of steam generators or other app. subjected to high temps. is formed of Na silicate soln., glycerol and graphite, with or without lubricating oil. Cf. *C. A.* **24**, 4604.

Colloidal mixture suitable for use as a cleaner, polisher and binder. EMIL L. JEASMAN. U. S. 1,790,272, Jan. 27. A satd. soln. of Na phosphate is mixed with sufficient bentonite to form a mixt. of heavy paste-like consistency.

Detergent for use on metals, painted surfaces, glass, etc. W. J. A. HUYZER. Brit. 335,005, July 26, 1929. Natural magnesite is ground to pass a 250-mesh screen, preferably being first ground to 100 linear mesh, heated to 900° to eliminate moisture and then further ground to 250 linear mesh, and may be mixed with various other detergent materials such as "petrol," olein, "methylated spirit" and NH_3 to form an emulsion.

Polish for metal ware. RICHARD BLASBERG. Ger. 512,838, Dec. 7, 1928. A mixt. of neutral soap soln., org. acids or salts, and alc. is used.

Composition for defrosting windshields. WM. M. WEGMANN. Can. 308,080,

Jan. 27. 1931. A compn. for melting ice and snow from windshields of automobiles consists of a fused mass contg. 6 parts of $CaCl_2$ and 1 part of NaCl.

Activating filaments. LINCOLN THOMPSON (to Victor Talking Machine Co.). U. S 1,790,449, Jan. 27. A filament which may be formed of Pt wire is amalgamated, treated with one or more activating substances (such as by electrolyzing in a soln. of $BaCl_2$ and $SrCl_2$) and then heated to drive off Hg.

Magnet cores. PHILIP N. ROSEBY (to Associated Telephone and Telegraph Co.). U. S. 1,789,477, Jan. 20. Particles of pure iron are covered with a coating of Fe phosphate by boiling them in a soln. of Zn phosphate; the particles are then covered with a binding material such as bakelite varnish, and a mass of the coated particles is formed into a solid body in a heated mold by pressure sufficient to give the product a sp. gr. approx. that of pure iron.

Painting in relief. MARIE A. MAJOR NÉE ODAU Ger. 514,086, Aug. 26, 1928 A waterproof, rapidly drying adhesive is used comprising crude crepe rubber 10 in C_2HCl_3 80, C_2Cl_4 20, AcOEt 25 and methylated spirit 15 parts. Powd. mica or like material is dusted on after applying the adhesive.

Sealing composition (substitute for sealing wax). J. LESIUK. Brit. 334,936, June 12, 1929. A sealing compn adapted for use without flame or heat comprises a mixt. of a "gum paper or similar fibrous material," a compd. such as a cellulose ester and a solvent for the latter, preferably with addn. of a sugar and with or without resinous material. The material is dispensed in collapsible tubes or the like and sets after a few min exposure to the air.

Coating articles such as airplane propellers with metal. WM. E. GWALTNEY (to Westinghouse Elec. & Mfg Co). U. S. 1,790,213, Jan 27. A material such as laminated fabric and phenolic condensation product having a normally smooth and nonporous surface is subjected to a superficial grinding to pull out one of the constituents and form counter-sunk recesses; metal such as Cu, phosphor-bronze or Cr is then mechanically deposited on the prepd. surface.

Friction material for brakes, clutches, etc. FREDERICK C. STANLEY (to Raybestos Manhattan, Inc.) U. S 1,790,176, Jan. 27 Asbestos fiber is used with about 1–5% each of powd or granular graphite and powd or granular Pb or other metal of relatively low m. p., held together by a hardened binder. Cf. *C. A.* **25**, 566

Dentifrice. AKTIESELSKAPET SI-KO. Fr. 690,714, Feb. 26, 1930. An acid dentrifice is made by grinding at a relatively high temp., *e. g.*, 70°, a mass composed of a silicic acid gel, water and glycerol and a compd. which will maintain the mass liquid at the temp. used while allowing it to coagulate at a lower temp., *e. g.*, tartaric acid, benzoic acid or boric acid. Cf. *C. A* **23**, 242.

Cellulose compositions for making dental plates. VERCINGÉTORIX AUGUSTE LAPIERRE. Fr 692,400, June 13, 1929 Cellulose acetate dissolved in a solvent and combined with ores, earths, mineral oxides, etc., is used for making dental plates, etc.

Destroying pests. BODO HABENICHT. Ger. 509,454, Nov. 18, 1928. Cuprous or mercurous tripyridyl and like complex metal pyridyl compds. are used. No method of prepg. the compds. is described.

Compositions for combating animal or vegetable pests, particularly for treating seeds. PERMUTIT A.-G. (Otto Liebknecht, inventor). Ger. 514,284, June 15, 1926 Antimony fluorides or oxalates or their double compds. with one another or with alkali compds., are used, alone or mixed with one another or with diluents, etc.

Device for producing foam for fire-extinguishing or other purposes. N. SANDOR Brit. 335,358, Sept. 9, 1929. Structural features.

Device for producing fire-extinguishing foam. JOHN R. HAMILTON. U. S. 1,790,621, Jan. 27. Structural features.

System for producing fire-extinguishing foam from water and dry foam-forming materials. RADCLIFFE M. URQUHART (to Amdyco Corp.). U. S. 1,790,125, Jan. 27. App. and various details of operation are described. Cf. *C. A.* **24**, 2849.

Fire-extinguishing foam. MINIMAX A.-G. Ger. 511,503, Oct. 1, 1925. Foam forming liquid such as saponin is satd. with CO_2 or similar gas under pressure in a suitable container.

Foam for extinguishing fires. OTTO TREICHEL. Ger. 513,165, Dec. 25, 1925 Rapid soln. of the foam producer, *e. g.*, saponin, is ensured by mixing it with a diluent, *e. g.*, china clay, or a protective colloid, *e. g.*, albumin.

Extinguishing fires. I G. FARBENIND. A.-G. (August Ruppert, inventor). Ger 513,191, Aug. 26, 1928. In extinguishing fires with CCl_4, production of $COCl_2$ is minimized by adding to the CCl_4 a hydrocarbon and NH_3 in small quantities. An addn of solvent naphtha 5, and NH_3 0.5-1% is suitable Cf. *C. A.* **24**, 2849, 3093.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Calculation of glass compositions from the batch and vice versa. C. E. GOULD AND W. M. HAMPTON. *Glass Ind.* 11, 249–52(1930).—The calcns. include these 3 factors which cause variations in the compn. of the glass: (*a*) presence of impurities in the raw materials, (*b*) loss of constituents from the glass by volatilization, (*c*) soln. of refractories in the glass. H. F. K.

Glass calculations simplified: primary calculations without the use of chemical symbols. R. R. SHIVELY AND V. H. REMINGTON. *Glass Ind.* 11, 223–6(1930).—Methods are given for calcg. the weight of glass produced from the batch, the percentage lost in melting, chem. substitutions in batches and the coeff. of cubical thermal expansion. H. F. K.

Fusing glass containing blast-furnace slag. I I. KITAIGORODSKII AND I. P. KAREV. *Keram. i Steklo* 6, 465–6(1930); cf. *C. A.* 24, 5954.—Investigations showed that granulated blast-furnace slag (compn. given) can be used as an admixt. in glass. Glass contg. 30% of its weight in blast-furnace slag was composed of silicic acid 70, alumina 3.2, CaO 16 and Na_2O 10%. The glass obtained was of good quality. The batch was made up of sand 1000, sulfate 275, soda 160, slaked lime 180 and charcoal 10 kg. The glass contained 15% Na oxide. M. V. KONDOIDY

Structure of glasses: The evidence of x-ray diffraction. J. T RANDALL, H. P. ROOKSBY AND B. S. COOPER. *J. Soc. Glass Tech.* 14, 219–29 T(1930); cf. *C. A.* 24, 4697.—Numerous glasses were subjected to x-ray analysis in an app. of the Debye-Sherrer type. With Cu K_α radiation a single intense band at 4.33 A. U. was obtained with vitreous silica. The strongest band for α-cristobalite occurs in almost the same position. Thus it appears that vitreous SiO_2 is composed of cristobalite crystallites, probably consisting of an av. of 20 mols. each. "Amorphous" or pptd. SiO_2 gives almost the same pattern, indicating that the difference between the cryst. and amorphous or vitreous states is one of degree, not of kind. Al and B do not destroy the SiO_2 lattice, while the strongly electropositive elements, as Ca and Na, do. The densities of glasses, their melting, electrolytic, expansion and viscous properties are briefly considered in the light of cryst. characteristics. Also in *Z. Krist.* 75, 196 214(1930). H. F. K.

Thermal endurance of glass. C. E. GOULD AND W. M. HAMPTON. *J. Soc. Glass Tech* 14, 188–204T(1930).—Numerous beakers were blown from the same tank providing a wide range in the beaker wall thickness. These were tested by heating a quantity of paraffin wax in them to a definite temp. and plunging the beaker and contents into cold water, this being repeated at 5° intervals until fracture occurred. The breaking temp. was found to rise as the thickness of the glass decreased. A math. investigation was carried out on the rise of stress in infinite flat plates of various thicknesses, on the assumption that the surface of the plate was cooled on one side in accordance with Newton's law and on the other was maintained const. Comparisons of the theoretical and the observed thermal endurances are given. H. F. K.

Bottle glasses with special regard to their stability. G. KEPPELER AND RICHARD MAENICKE. *Sprechsaal* 64, 7–10, 28–30, 46–9, 65–8(1931).—A series of beer glasses was analyzed and their solubilities in beer were detd. Compns. were plotted in both the 4-component system, CaO–SiO_2–Al_2O_3–Na_2O and in the 3-component system, CaO–SiO_2–Na_2O. C. H. LORIG

Data on grinding and polishing (glass). F. W. PRESTON *Glass Ind.* 11, 235 (1930). H. F. K.

Suggested relations of sodium silicate, adhesion tension and angle of contact, to liquid absorption in clays. GEO. I. WHITLATCH. *J. Am. Ceram. Soc.* 14, 154–61 (1931).—This is a progress report in a study of the effect of electrolytes on the liquid absorption of clays tempered to max. plasticity. Na silicates have an influence on absorption when added to the tempering water. Observed results are explained on the basis that the Na silicate reduces the angle of contact and increases the adhesion tension of the clay–water system. An extension of this principle may explain, in part at least, some of the phenomena of deflocculation and plasticity. C. H. KERR

Organic compounds as electrolytes and their effect on the properties of clay slip and on the life of plaster molds. C. W. PARMELEE AND C. G. HARMAN. *J. Am. Ceram. Soc.* 14, 139–47(1931).—Ethylamine, piperidine or tetramethylammonium hy-

droxide are good electrolytes and attack molds less than does Na_2CO_3 or Na silicate. C. H. KERR

Strength tests on roofing tile. NORMAN W. KELCH. *J. Am. Ceram. Soc.* **14,** 133–8(1931).—Rupture of the whole tile on standard edges seems to be the most reliable test. The Clay Products Inst. of Calif. has adopted these specifications: (*a*) absorption, not over 15% during 48 hrs. in water; (*b*) soundness, free from injurious cracks and ringing clear when lightly tapped; (*c*) strength (flat pan or bottom tile or flat shingle or flat decorative tile are not included), when supported on turned-down edges at points 6" each side of the center, and with load concd. at the center, the av. breaking load for 5 tiles shall be not less than 400 lb. C. H. KERR

Ceramic testing and research laboratories, Ottawa. HOWELLS FRECHETTE. Can. Dept. Mines, Mines Branch, *Memorandum Series* No. **44,** 7 pp.(1931); cf. *C. A.* **24,** 478. ALDEN H. EMERY

Heat efficiency in ceramic burning ovens. OTTO TH. KORITNIG. *Sprechsaal* **64,** 63–5(1931); cf. *C. A.* **24,** 3336. C. H. LORIG

The heat balances of some ceramic kilns. HOWARD H. MANSUR. *J. Am. Ceram. Soc.* **14,** 89–124(1931).—Two round downdraft kilns, 1 muffle, 1 rectangular horizontal draft, 1 semi-continuous and 1 continuous kiln were investigated. Results and a bibliography are given. C. H. KERR

Waste gas utilization from the muffle furnace. E. GUNTHER. *Sprechsaal* **63,** 975 (1930). C. H. LORIG

Testing laboratories for refractory materials. L. LITINSKY. *Feuerfest* **6,** 1–11 17–25, 33–9, 49–57(1930). E. H.

The determination of zinc in refractory bodies and slags. EDWARD E MARBAKER *J. Am. Ceram. Soc.* **14,** 162–75(1931). The method consists in pptg. Fe and Zn sulfides from an ammoniacal soln. contg. the 3 ions, in which the Al_2O_3 is held in soln. by the presence of citric acid. C. H. KERR

Construction of [enameled] refrigerator linings. C. H. WOLFF. *J. Am. Ceram Soc.* **14,** 148–53(1931). C. H. KERR

Refractory products in metallurgy (FORESTIER) **9.** Experiments on different glasses used in bottle manufacturing (KEPPELER) **16.** A new arrangement for the granulation of blast-furnace slag with water and air (SPIES) **9.** Examination of grain sizes in clays (GRENNESS) **15.** Plating pipes with metals such as Zn and lining them with enamel (U. Glass. MAX METH (to Isaac R. Stewart). U. S. 1,789,658, Jan. 20 A glass having a low coeff. of expansion is formed from a batch which may contain soda 9, lime 16, silica 74 and a Be compd. 1%.

Glass. PITTSBURGH PLATE GLASS CO. Ger. 511,666, Feb. 22, 1929. In rolling plate glass, air, gas or vapor is blown under the glass as it leaves the rollers.

Glass. GLASFABRIK SOPHIENHÜTTE RICHARD BOCK G. M. B. H. Ger. 513,453, Apr. 18, 1926. A borosilicate glass resistant to chem. influences contains at least 4 oxides of elements of the second periodic group, at least 1% of each oxide being included. A suitable compn. has alkali up to 15, Al_2O_3 at least 6, B_2O_3 not more than 5 and SiO_2 more than 50%, together with the 4 oxides as stated above. Part or all of the Al_2O_3 may be replaced by ZrO_2.

Hollow glass. GUSTAV KEPPELER. Ger. 512,904, Mar. 3, 1927. Hollow glass is improved by adding material which evolves gas combining with alkali on further heating, *i. e.*, substances giving off H_2O, CO_2, SO_2, H_2S, HCl, H_2SO_4, HCOOH, CH_3COOH, etc.

Glass making. SOC. ANON. DES MANUFS DES GLACES ET PRODUITS CHIM. DE SAINT-GOBAIN, CHAUNY ET CIREY. Fr. 692,390, June 11, 1929. Means is described for pouring out the molten contents of the crucibles.

Feeding mold charges of molten glass. LEONARD D. SOUBIER (to Owens-Illinois Glass Co.). U. S. 1,789,480, Jan. 20. Mech. features.

Blocks for building glass-melting tanks. P. G. WILLETTS (to Hartford-Empire Co.). Brit. 334,799, Dec. 15, 1928. The blocks are heat insulated over the major portion of their outer surface, other parts such as the edges being left uncovered so that the joints between the blocks may be kept cool. Various structural details are described. Cf. *C. A.* **24**, 3337.

Apparatus for making hollow glass articles such as bottles. BYRNE MCGOVERN (to Owens-Illinois Glass Co.). U. S. 1,789,471, Jan. 20. Structural features.

Apparatus for manufacture of molded glass articles such as bottles or jars. PIERRE ARBEIT (to Hartford-Empire Co.). U. S. 1,790,633, Jan. 27. Structural features.

Blown glass articles such as "paste mold ware." WM J. WOODS and DAVID E. GRAY (to Corning Glass Works). U. S. 1,790,397, Jan. 27. The articles are progressively and sequentially blown from a ribbon of glass as it moves away from the point of its formation. App. is described.

Glass-making furnace. COMPAGNIES RÉUNIES DES GLACES ET VERRES SPÉCIAUX DU NORD DE LA FRANCE. Fr. 691,883, Mar. 13, 1930.

Apparatus for making sheet glass. MAX BICHEROUX. Ger 514,113, Aug. 26, 1928. Addn. to 423,449.

Apparatus for rolling and annealing glass plates. N.-V MIJ. TOT BEHEER EN EXPLOITATIE VAN OCTROOIEN. Ger. 511,244, April 11, 1928. See Brit. 309,444 (*C. A.* 24, 703).

Annealing glass. N.-V MIJ. TOT BEHEER EN EXPLOITATIE VAN OCTROOIEN. Ger 511,668–9, April 8, 1928.

Glass-annealing leer. KARL E PEILER (to Hartford-Empire Co.). U. S. 1,790,630, Jan. 27. Structural features.

Leer for annealing glassware. VERGIL MULHOLLAND (to Hartford-Empire Co.). U. S. 1,790,434, Jan. 27. Structural features of a continuous tunnel leer with conveyor and temp.-controlling flues.

Rust-preventing composition. GLASFABRIKEN UND RAFFINIEREN JOSEF INWALD A.-G. Ger. 513,372, Aug. 7, 1926. A compn. for protecting molds for glass and glass-working tools against rust comprises a mixt. of mineral oil and ceresin m. 35–40° emulsified with CaO 5 and concd. NaOH soln. 2%.

Safety glass. LIBBEY-OWENS GLASS CO. Fr. 691,946, Mar. 14, 1930. The intermediate layer, having a basis of cellulose, for the manuf. of safety glass is treated with a solvent of high b. p. and low vapor pressure such as dibutyl phthalate so that the formation of bubbles during use is avoided. Cf. *C. A.* **24**, 4132.

Safety glass. SOC. DES USINES CHIM. RHÔNE-POULENC. Fr. 690,803, Feb. 28, 1930. Safety glass is made by dipping 2 sheets of glass and an intermediate sheet of plastic material having a basis of cellulose acetate, nitrocellulose, etc., superficially softened and free from volatile solvents, into a bath composed of plastifiers for the plastic material, removing air bubbles, pressing the sheets lightly together and then removing them to an autoclave into which a heated gas under pressure is introduced. Cf. *C. A.* **25**, 1052.

Laminated safety glass. W. C. DOUGAN. Brit. 334,858, June 6, 1929. Various details of app. and procedure are described for uniting assembled sheets in a tank contg. adhesive and enclosed in a heated pressure chamber.

Adhesives. SOC. DES USINES CHIM. RHÔNE-POULENC. Fr. 690,751, Feb. 27, 1930. Adhesives are made by polymerizing vinyl butyrate, in the absence of water, mixed with softening or adhesive agents or an org. solvent. The product may be used for *joining the component sheets of safety glass.*

Machine for the matting of the interior surface of electric bulbs and similar glass containers. DRAMMENS LAMPEFABRIK A/S. Norw. 45,413, July 30, 1928. The matting is carried out by treating with etching liquid, washing with water and drying with air.

Open-trough washer for breaking up lump clay, etc. JAKOB HILBER. Ger. 513,107, Feb. 13, 1927.

Cleaning ollas or other clay products. ROBERT W. MCCARTY and CALVIN W. MCCARTY. U. S. 1,789,657, Jan. 20. The outer surface of the olla or the like is treated with an acid soln. such as HCl and is then sanded and brushed. App. is described.

Fireproof tile. CHRISTIAN W. HALL. U. S. 1,790,418, Jan. 27. Tiles are formed of ingredients such as cinders and other materials of the approx. analysis: SiO_2 24.4, Fe oxide 1.4, lime 16.4, Al_2O_3 10.6, MgO 2.3, Na_2CO_3 3.3, S 5, and carbonaceous matter 33.6% with addn. of about 14% of moisture.

Driving means for mechanical stoker for brick or tile kilns. INGENIEUR GAIRING MASCHINENFAB. G. M. B. H. Ger. 513,099, Jan. 22, 1930.

Indirectly heated ceramic tunnel kilns. PORZELLANFABRIK KAHLA, ZWEIGNIEDERLASSUNG FREIBERG. (Ludwig Wirth, inventor). Ger. 513,458, June 10, 1928. The gases in the kiln circulate countercurrent to the materials. Cf. *C. A.* 25, 791.

Device for transferring cement meal from the granulating drum to the kiln. G. POLYSIUS A.-G. Ger. 514,069, Feb. 23, 1930.

Ceramic furnaces. ARMAND BISCH. Fr. 690,979, Mar. 3, 1930.

Tunnel kiln for pottery, etc. R. M. D'ARLEUX and E. VIOLETTE. Brit. 335,154, April 15, 1929. Structural features.

Container for use in firing ceramic goods. HANS STÖBERER. Ger. 514,070, May 20, 1930.

Ceramic body. HANS NAVRATIEL and ALBRA H. FESSLER (to A C Spark Plug Co.). Can. 308,308, Feb. 3, 1931. A ceramic batch contg. Al_2O_3, SiO_2 and Li, the Al_2O_3 being in excess of the SiO_2, is completely fused and rapidly cooled to produce small crystals. The grog thus produced is intimately mixed with clay, molded and fired. Cf. *C. A.* 24, 2853, 3338.

Ceramic masses. JAMES MCC. LAMBIE and DONALD W. ROSS. Can. 308,218, Feb. 3, 1931. A ceramic casting slip contains NH_4OH 0.10–0.62, NaOH 0.010–0.14, Rochelle salt 0.010–0.10, oxalic acid 0.010–0.10 and litharge 0.010–0.10% of the dry mix.

Porcelain articles. GIOVANNI FUSCHI and MAURIZIO KORACH. Fr. 691,744, Mar. 11, 1930. Porcelain articles which are afterward to be subjected to heat are baked without glaze and then polished, whereby cracking of the glaze is avoided.

Insulators. I. G. FARBENIND. A.-G. Fr. 690,835, Feb. 28, 1930. An insulating substance for spark plugs is composed of a mass (contg. at least 60% of Al_2O_3) the basis of which is corundum and the surface of which is polished. Cf. *C. A.* 24, 3338.

Molds for Carborundum, etc. OSKAR DIENER. Ger. 513,445, Jan. 12, 1927. Molds made of hard-baked "artificial carbon" are used for making hard articles from powd. materials by compression at a temp. above 1300° and a pressure of 50–300 kg. per sq. cm. The manuf. of whetting stones from Carborundum or the like, with or without addns. of less refractory material, is instanced.

Refractory material. BORGESTAD FABRIKKER. Norw. 46,250, June 24, 1929. The material contains exclusively or chiefly compds. of SiO_2, Al_2O_3 and MgO. The content of free MgO should not exceed 25%. The content by wt. of SiO_2 should not exceed 0.78 MgO + 0.3 Al_2O_3. The content of Al_2O_3 should not exceed 2.55 MgO + 0.85 SiO_2. The content of MgO should not be less than 1.33 SiO_2 + 0.40 Al_2O_3.

Refractory bricks, etc. HERAEUS-VACUUMSCHMELZE A.-G. and WILHELM ROHN. Ger. 513,457, Aug. 30, 1925. Granular natural or artificial corundum, preferably mixed with 5–20% of calcined Al_2O_3, is sintered at 1300–1400° in a sheet-iron mold, without addn. of a binder.

Refractory products from silicon carbide. MINER L. HARTMANN (to Carborundum Co.) U. S. 1,790,474, Jan. 27. In order to increase its resistivity to oxidizing conditions at high temps., "commercial" SiC is treated (suitably by magnetic sepn. and use of acid) to effect removal of compds. of easily reducible metals (those falling below Mn in the electrochem. series and capable of accelerating the oxidation of SiC at high temps.), mixed in granular form with a bond contg. kaolin clay and feldspar (the bond also being free from catalytic materials which would accelerate oxidation of the SiC) which reduces the permeability of the product to penetration by oxidizing gases, shaped and fired.

Refractory lining construction suitable for electric furnaces. HARRY R. ORWICK and EDWIN J. BOGNAR (to Corundite Refractories, Inc.). U. S. 1,789,474, Jan. 20.

Glazed ceramic tiles with curved front surfaces. NILS H. CEDERQUIST. U. S. 1,790,227, Jan. 27. Various mech. details of manuf. and glazing are described.

Fusing glass onto enameled metal. HILDEGARD ADLER. Austrian 119,976, June 15, 1930.

Glazing wooden insulators. PORZELLANFABRIK PH. ROSENTHAL & Co. A.-G. Ger. 514,327, Mar. 21, 1926. The wood is coated to protect it against carbonization and a fused ceramic glaze is then applied by spraying.

Oven, dip tank and conveyer suitable for enameling metal plates, etc. VERNIE A. FOX (to Young Brothers Co.). U. S. 1,790,501, Jan. 27.

Zirconium opacifiers for vitreous enamels. CHARLES J. KINZIE (to Titanium Alloy Mfg. Co.). U. S. 1,789,311, Jan. 20. An opacifier contg. Na Zr silicate and Zr silicate is prepd. by heating a mixt. of Zr silicate about 78 and Na_2CO_3 about 22% to about 900–950° and cooling and disintegrating the product.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Impermeability and permanence of cements. EDMOND MARCOTTE. *Ciment* **35**, 476–82(1930); **36**, 6–12(1931).—The French cements are briefly described and the classic work of Michaelis on pozzuolanas is reviewed in detail. The slowness of the reaction between the lime and the silica is brought out. Apparently good results have been obtained with pozzuolanas, especially against sea water. The French pozzuolana, *gaize*, found near Paris, is being ground commercially with portland cement to produce a cement resistant to sea water. It contains about 33% alkali-sol. SiO_2. F. O. A.

The evolution of German cement specifications. K. A GOSLICH. *Tonind.-Ztg.* 55, 4–7(1931).—Historical. F. O. A.

Temperature and humidity control in cement testing. H. S. MATTIMORE. *Eng. News-Record* **106**, 36(1931).—High-strength cement, especially the product termed "high-early-strength cement," is more sensitive to temp. and humidity conditions during testing than the cement produced several years ago. The tolerance of 5% allowed in specifications is too broad in some cases, instances having occurred of specimens maintained at 65° showing strengths below that specified, while similar specimens maintained at 70° or over were satisfactory. The moist-air cabinet employed in the Pennsylvania Dept. of Highways is described briefly. The humidity is maintained at 95–98% by water flowing down the sides of brass screens located about $^3/_8$ in. from the walls of each section, the temp. of the water being adjusted before it enters the cabinet. Records over a period of many weeks show a max. variation of 2° from 70°. R. E. THOMPSON

Cement admixtures, their action and absorbing power. P. MECKE. *Tonind.-Ztg.* 55, 33–6(1931).—Water glass, oleic acid and a few other water-repellent materials in rather large concn. (as high as 8%) did not yield very good results. F. O. A.

Trass and sand as additions to cement. R. GRÜN. *Chem. Erde* **5**, 113–45(1930):—Tests were made on the addn. of trass and sand to portland cement and slag cements, the materials being either ground together or simply mixed. The products were tested after exposure to air, water or $MgSO_4$ soln. for various periods of time (3 days to 24 months). The addn., by simple mixing, of up to 40% of trass increases the strength and resistance to wear of the product B. C. A.

The chemistry of Rhenish trass. HEINRICH HART. *Tonind.-Ztg.* **55**, 65–6, 84–6 (1931).—With solns. of C_6H_6 and $CHBr_3$ the trass was sepd. into fractions of different sp. gravities, the lighter contg. more water in combination. The trass is variable in mineralogical compn.; it seems to consist of alkali aluminosilicates in varying stages of hydration. F. O. A.

Technical problems in the portland cement industry. EMIL SARLIN. *Tek. Fören i Finland Förh.* **50**, 219–26(1930).—Historical with reference to practice in Pargas cement works (Finland). H. C. DUUS

Free lime in portland cement and volume stability. KATSUZO KOYANAGI. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding, 496–7(1930) (in German).—One group assumes that, in burning, only a part of the CaO combines chemically, with formation of Ca silicate or Ca_3 silicate; the other group that all CaO combines chemically to form Ca_3 silicate. The former believe that no more basic silicate exists than Ca_3 silicate and assume the presence of greater amts. of free CaO or CaO in solid soln. in the portland cement. Those who favor Ca_3 silicate as the main ingredient of clinker deny the presence of free CaO. The cause of swelling of portland cement was investigated by using the recent glycerol method of detg. free CaO. The amts. of free CaO in numerous clinker samples of various degrees of burning were detd. and compared with the vol. stability of the cements. CaO "swellers" were added to stable cement to make various mixed cements, and tested in the same way. Then CaO "swellers" were made stable by storage, samples being taken from time to time and tested for free CaO and vol. stability. Swelling cements were found to contain considerable quantities of free CaO; well-burned, stable cements, very little. At a fineness equiv. to 4% residue on a 4900-per-sq. cm. screen, if free CaO in cement is above 1% the boiling tests show instability; if free CaO exceeds about 2.2% both boiling and water tests show instability. Whether the free CaO in cement detd. by the glycerol method is absolutely free or in the form of so-called "exploded particles" is not yet explained, but it is certain that this CaO has an intimate relation to vol. stability of portland cement. Tensile strength of almost all swelling cements is low, and if by storage they are rendered stable their tensile strength is increased. It is

probable that there is some relation between tensile strength and swelling tendency. E. M. SYMMES

Automatic buret for measuring mixing water. F. V. REAGEL. *Eng. News-Record* **106,** 37(1931).—A brief description is given of an automatic buret, accurate to approx. 0.25 cc., for measuring mixing water for cement mortar briquets. R. E. T.

Testing oil-carrying quality of earth. J. W. POWERS. *Eng. News-Record* **106,** 38 (1931).—The method employed by the Arizona Highway Dept. is outlined. The material, graded to specifications, is mixed with what is considered sufficient oil (asphaltic residue 65% plus by the Brown evaporator) and allowed to stand overnight for absorption. That portion passing a 10-mesh sieve is hand-tamped into a circular mold, 3 in. in diameter and 2 in. deep, and is further compacted by applying a load of 2000 lb. per sq. in. by means of a universal testing machine. Pressure is applied to the material by means of a die cut to fit the mold, and the material is pressed against a face plate so as to bring it flush with one end of the mold. The bottom is sealed with paraffin, after which the whole app. is immersed in water. Appreciable swelling above the original plane at the end of 12 hrs. or more is evidence of instability with oil. The max. amt. of swell which a material may have that is considered safe to use has been tentatively set at $^1/_{16}$ in. R. E. THOMPSON

Stone in 1929. A. T. COONS. Bur. Mines, *Mineral Resources of the U. S. 1929,* Pt. II, 229-66 (preprint No. 19, published December 30, 1930). E. H.

Methods used in testing masonry specimens for bending, tension and shear. NORMAN W. KLICH *J. Am. Ceram. Soc.* **14,** 125–32(1931).—Twenty-four walls, $4^1/_2$ ft. wide, $5^1/_2$ ft. high and 8–12 in. thick, were tested for bending after 60 days, and after 6 months. Aging of lime mortar is essential. Failures in shearing tests were also due to immature mortar C. H. KERR

Effect of the mixing water on mortar strength. E. PROBST AND K. E. DORSCH *Zement* **19,** 1009–11(1930).—A general survey of the concrete construction and materials tests in the principal cities of Germany showed considerable differences in concrete and mortar strengths which apparently were due to chem. differences in the mixing waters used. Two ordinary portland cements, a high-early-strength cement, a slag cement, and an aluminous cement were compared in mortars mixed with distd. water and Karlsruhe water having an av. hardness equiv. to 150 mg. CaO per l. It was found that the distd. water gave roughly 10% higher tensile strength but considerably lower compressive strength in general than did the Karlsruhe water. H. F. K.

Aggregates and the physical properties of concretes: their coefficients of elasticity and their resistance to compression, tension, bending, shear and impact. R. DUTRON *Rev. matériaux construction trav publics* **1930,** 258–62, 293–8, 343–9, 383–9, 431–5, 473–7.—Expts. were made with 2 cements in 3 proportions, at 3 consistencies and with 3 gradings of aggregate. The chief object was to compare in respect to phys. properties concretes made in whole or in part with crushed stone (mostly porphyry) with those from water-worn aggregates, including sands and gravels from the rivers Rhine and Meuse. The rounded aggregates gave better compressive strength. It is covered by the formula, $C = K[(c/w) - K]$ within ±15%, for the cement-water ratio c/w from 1.3 to 2.5. The coeff. of elasticity under compression was obtained from the expansion of two sides of a cube. It increases with the fluidity of the mix, but decreases as the cement increases It depends upon the quality of the cement, upon the grading of the aggregate and upon the ratio of coarse to fine aggregate. Water worn aggregate gives a stiffer concrete under compression than does crushed stone Tensile results were different, crushed coarse aggregate giving better results than gravel and fine rock better than sand. The ratio of compressive to tensile strength decreases parabolically with age, for crushed stones it lies in the range 0.093 to 0.075 and for river aggregates, 0.070 to 0.052. The coeff. of elasticity under tension depends upon the age. Crushed stone produces concrete of max. deformability, while rounded aggregates make concrete much less deformable under tension. The formulas are $E_T = 34700\ T^{0.600}$ and $E_T = 43200\ T^{0.622}$, resp. E decreases with repeated loading. E_T is very similar to E_C for loads equal to the same fraction of the ultimate loads The flexural strength within 12.5% equals 1.63 times the tensile. The resistance to shear was detd. by making beams with an offset central part and was found to be closely proportional to the compressive strength, S (kg./sq. cm.) = $16 + 0.32\ C$. The resistance to impact was detd. by allowing a 5-kg. ball to fall 10 cm. the first time, increasing up to 180 cm. by increments of 10 cm., thereafter remaining const. until rupture. Specimens were broken under compressive and flexural impacts. Specimens made of crushed rock withstood the pounding better than those made of sand and gravel. F. O. A.

A percentage balance for concrete aggregates. W. J. EMMONS. *Eng. News-*

Record **106,** 37(1931).—A percentage balance for use in the rapid detn. of the grading of concrete aggregates is described. The balance, which has a capacity of 13 kg. and sensitivity of 1 g., has 2 scale arms. Sliding poises enable 5 kg. of coarse aggregate to be weighed with one arm and 500 g. of sand with the other. The percentage of material passing each screen can be read directly. The grading of a sample of coarse aggregate can be obtained in about 4 min., and of a sample of sand in approx. 10 min. The cost of the balance is about $50. R. E. THOMPSON

The protection of concrete with coatings containing metallic aggregates. GEORGE DUPONT. *Ciment* **35,** 462–74(1930).—Mortars made of metallic aggregates and cement are useful in providing durable and impervious coatings for concrete exposed to sea water or other aggressive solns., to frost action or to erosion of running water. F. O. A.

Rocker screen speeds up field test operations. C. R. STOKES. *Eng. News-Record* **106,** 39(1931).—A brief description is given of a rocker screen set for test-pitting and controlling concrete mixts. by means of which the time required for screening can be reduced to 50% of that required for hand screening. R. E. THOMPSON

The drying of wood with the aid of chemical methods. FRIEDRICH MOLL. *Kunststoffe* **20,** 270–1(1930).—A discussion of the physicochem. factors affecting the removal of water from wood, with a list of patents on processes involving covering of the wood with chem. agents, boiling with non-aqueous solvents, or impregnation with oil. The first 2 methods are said to be practically never economical, while the last can be used for a few high-priced products. I. H. ODELL

Some aspects of wood preservation in Australia. J. E. CUMMINS, H. E. DADSWELL AND G. F. HILL. *J. Council Sci. Ind. Research* **3,** 133–46(1930).—The results of a survey of the economic situation in Australia with reference to timber utilization and preservation are presented. Jarrah, karri and Tasmanian stringy bark are the main woods used for railway sleepers and transmission poles. The only treating plant is located in W. Australia, where 8,000,000 cu. ft. has been treated by the Powell process since 1911 and 750,000 cu. ft. since 1926 by the fluarizing process (NaF, As_2O_3 and Na dinitrophenol; cf. *C. A.* **22,** 422). An outline of the research program of the govt. Forest Products Lab. is included. The relation between durability and the chem. compn. of wood is discussed. The toxicity to wood-destroying fungi and to termites of the extractives and volatile oils of cypress pine (genus *Callitris*) is being studied. Other naturally resistant woods will also be investigated. A brief account of termites and their habits is given. ALFRED L. KAMMERER

New developments in mine-prop preservation. WILHELM ENGELS. *Intern. Bergwirtschaft Bergtech.* **23,** 339–45(1930).—The results of tests with Fluralsil, a new preservative for mine timbers, are presented. Fluralsil is a water-sol. cryst. salt (compn. not given) highly toxic to wood-destroying fungi and having the property of being fixed by wood fiber and therefore non-leachable. On account of these qualities empty-cell treatment processes may be used for the injection of its solns. into wood, thus effecting a considerable economy in the cost of preservative and subsequent seasoning of the treated wood. A 2–3% soln. is recommended. ALFRED L. KAMMERER

A new arrangement for the granulation of blast-furnace slag with water and air (SPIES) **9.** Preparation of quick-drying wood stains (TODD) **25.** Treating gypsum for cement production (U. S. pat. 1,790,023) **18.** Impregnating textiles, wood and other materials (Brit. 335,247) **25.** Working up scrap rubberized fabric (Ger. pat. 511,087) **30.** [Cement in production of] H_2SO_4 (Can. pat. 308,293) **18.**

Cements. NATIONAL BUILDING MATERIALS, LTD. Fr. 690,967, Mar. 1, 1930. A cement consists of a granulated or finely powd. mixt of $CaCO_3$ and $MgCO_3$ with their respective oxides. A colloidal material may be added to retard the cement or another substance such as $CaSO_4$ to accelerate it.

Cement, lime, etc. AUGUST BUES. Ger. 505,258, April 14, 1928. Cement, lime, etc., are manufd. in a shaft into which the raw materials are blown at the top, while a mixt. of fuel and air is blown through an upwardly directed nozzle at the bottom. The improvement consists in introducing the raw materials in sludge form through a downwardly directed nozzle.

Lime and cement. HUGO VIERHELLER. Ger. 511,513, Oct. 3, 1929. The water content of crude lime and cement sludge is diminished by adding a small quantity of waste contg. animal or vegetable decompn. or fermentation products to the slaking water. Liquid manure is mentioned as the example.

Fused cement. ERNST MOYAT. Ger. 511,521, Nov. 18, 1924. The starting materials (*e. g.*, bauxite and lime) are blown into a rotating heated cylinder with fuel and the crust formed in the cylinder by the reaction is scraped off and ground.

Oxychloride cement compositions. E. WOOD. Brit. 335,428, Nov. 5, 1929. In forming products from ingredients such as MgO, $MgCl_2$ and sand, the oxychloride soln. is divided into 2 portions, one of which is heated to the b. p., allowed to cool and added to the other portion together with sufficient water to bring the sp. gr. to between 16° and 24° Bé. The sand is purified as by washing with a NaOH soln., and aniline dyes, pigments, etc., also may be added.

Silicate cement for binding mineral aggregates, sawdust, etc. CEMSIL SOC. ANON. IT. and G. BOGGERO. Brit. 334,831, March 9, 1929. A soln. of **alkali metal** silicate or a mixt. of silicates is treated with a weak acid such as CO_2, SO_2 or H_3BO_3 or acid salts with const. stirring up to the max. permissible degree preceding coagulation and when used for binding mineral aggregate, sawdust, bone dust, cement or other materials a fixing agent such as $CaCl_2$ is used for treating the product. The waterproofing properties of the soln. may be improved by adding S (preferably in colloidal state). Various details are given for forming and treating artificial stone slabs, etc.

Waterproof cement. PAUL MECKE. Ger. 512,876, July 7, 1925. Dry powd. NH_4 or alkali salts are fused or mixed with fatty acid, and mixed with cement or lime. Thus, $(NH_4)_3PO_4$ is well mixed with oleic acid and the product mixed with sand and cement.

Water-glass cements, etc. EMIL HORNSTEIN. Austrian 119,743, May 15, 1930. In the manuf. of water-glass cement or artificial stone with the use of oxides such as CaO or MgO, the latter are added in a finely divided, but partly deactivated, state prepd. by treating the sintered oxides with hot water or steam, under pressure if desired. Too rapid hardening is thus avoided. The other customary fillers may be included.

Treating blast-furnace slag. SVEN MICHELSEN. Austrian 119,963, June 15, 1930. Blast-furnace slag for use in making *cement* is rendered more reactive by mixing it with about 5% of $CaSO_4$ or other compd. of S and heating the mixt. with a reducing flame so that part of the MnO in the slag is converted into MnS. The CaO content of the product is then adjusted in known manner.

Rotating furnace for cement, etc. ADOLPHE BUSCH. Fr. 692,300, Mar. 19, 1930. Method of feeding the substance to be calcined into the furnace is described.

Rotary tube kiln for fused cement. ARNO ANDREAS. Ger. 513,409, June 19, 1928.

Casting concrete dams, walls of buildings, etc. STEFAN D. TÖNNESSEN and ALFRED T. KNUDSEN. U. S. 1,789,791, Jan. 20. The concrete is cast against molds of glass plates which are left in place until the hardening and contracting of the concrete has progressed so far that irridescent zones visible between the glass plates and the surface of the concrete have disappeared.

Road-making composition. VERKAUFSVEREINIGUNG FÜR TEERERZEUGNISSE G. M. B. H. Ger 511,456, Oct. 8, 1926. Anthracene oil is oxidized sufficiently to render it capable of taking up water, and the product is mixed with pitch. A liquid compn. which can be applied in wet weather is thus obtained. The oxidation may be effected at 100° with air.

Pavement construction. OLIVER M. PADDLEFORD. U. S. 1,789,447, Jan. 20. Rocks and clay and asphalt are separately heated, and then mixed so that each rock is encased in an elastic adhesive mixt., the mass is poured while hot on a roadway, and is rolled while hot.

Flooring or paving materials. R. J. CUTHBE and S. W. M. SILVER. Brit. 335,150, March 13, 1929. A waterproof material is manuf. by securing to rubber, wood blocks, linoleum or tiles or the like a thin Pb sheet, which in turn is secured to a foundation by a bituminous or other waterproof cement. Various details of manuf. are described.

Artificial stone. EMIL TELTSCHIK & CO. Austrian 119,974, June 15, 1930. Comminuted ivory nuts are mixed with a magnesia cement. The comminuted nuts should be pretreated by steeping in dil. acid or alkali at atm. temp., washing and drying. Other fillers may be included. Details are given. Cf. *C. A.* 24, 2857.

Artificial stone. DEUTSCHE HERAKLITH A.-G. Ger. 513,097, Sept. 11, 1928. Plates, etc., made from fibrous materials and a sorel cement are set and dried by blowing hot gases through the material in alternating directions. App. is shown. Cf. *C. A.* 25, 793.

Artificial marble. J. J. BURKE. Brit. 335,107, Nov. 8, 1929. See Fr. 684,077 (*C. A.* 24, 5457).

Porous building material. GEORG O. RICHTER & SCHÄDEL. Ger. 513,279, Sept. 3, 1927. In the manuf. of porous building material from a mixt. of cement, etc., and Al or other metal that evolves a gas when the mixt. is treated with water, the metal used is activated, *e. g.*, by heating it with $HgCl_2$.

Bituminous roofing. WILHELM REINER. Ger. 512,707, Mar. 7, 1928. Addn. to 367,476. The material contains finely ground bituminous material, such as asphaltlime stone, as filling material, mixed with a relatively small quantity of bitumen. Blast-furnace slag or fine sand may be added. Cf. *C. A.* 24, 2574.

Sheet roofing material. HAROLD L. LEVIN (to Anaconda Sales Co.). U. S. 1,789,443, Jan. 20. A foundation layer such as asphalted roofing felt is provided with a coating comprising granular material such as crushed slate, the individual particles of which are coated with a film of Cu, Pb or other suitable metal.

Sheets or slabs of asbestos and cement mixtures. R. KUNZ. Brit. 335,106, Nov. 23, 1928. Slabs or the like formed on a paper machine from a mixt. such as asbestos and cement are rendered more resistant to disintegration from sudden heating by adding about 5% of light mineral lubricating oil to the mixt. at some stage of the manuf.

Laminated material for airplane construction, etc. FREDERICK H. AULD. U. S. 1,789,288, Jan. 20. Celluloid sheets the surfaces of which have been partially dissolved are used for uniting a metal surface layer such as Al with an underlying layer of composite wood construction.

Corrugated building board of hot-pressed vegetable fiber. WM. H. MASON (to Masonite Corp.). U. S. 1,789,825, Jan. 20. A product intended for use in building as a substitute for corrugated sheet iron is prepd. by pressing to give the material a sp. gr. of 1.0 or more. Various details of manuf. are described and as raw material there may be used wood waste pulped and treated with 1.5–3.5% of paraffin or petrolatum.

Pressed fiber board. DANIEL M. SUTHERLAND, JR. U. S. 1,790,178, Jan. 27. A marginal edge of the material is compressed to a greater d. than the body of a pressed fiber board or plank and is united with the main body of the board by a zone of varying d., so that nailing is facilitated.

Plaster-board. ALEXANDER S. SPERR (to Certain-teed Products Corp.). U. S. 1,790,252, Jan. 27. Mech. features and app. are described.

Sheet material for use as a lumber substitute. T. B. MUNROE and E. C. LATHROP. Brit. 335,052, Sept. 14, 1929. Cellulosic material such as bagasse, contg. about 50% water, is subjected to a pressure of about 500 lbs. per sq. in. and a temp. of about 175°,

after a preliminary fermentation, digestion, beating and sheeting on a paper machine. A minor proportion of paper stock may be added.

Artificial wood. KURT KÜRSCHNER. Fr. 691,004, Mar. 3, 1930. In making objects from reduced or waste wood, the binding agent used is a soln. of wood or cellulose made by means of caustic soda lye, CS_2 or ammoniacal CuO, which is afterward removed.

Apparatus for impregnating lumber with preservatives. HENRY B. CLARK. U. S 1,789,999, Jan. 27. Structural features.

Preserving wood. RÜTGERSWERKE. A.-G. (Hans Pflug, inventor). Ger. 511,568, Jan. 3, 1928. A soln. of $HgCl_2$ contg. less than double the equiv. amt. of alkali cyanide is used. Other insecticides, fungicides and anti-inflammable agents may be added. Examples mention $HgCl_2$ and KCN with $Na_4As_2O_7.2H_2O$, $Na_2HPO_4.12H_2O$ and NH_4OH.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND ALDEN H. EMERY

Experiences in Sweden with motor fuels containing alcohol. E HUBENDICK *Petroleum Z.* **26**, *Motorenbetrieb und Maschinen-Schmierung* No. 12, 3-9(1930).—"Lätt bentyl," a motor fuel contg. 25-30% of alc., has met with favor in Sweden and is used both in summer and winter. It has a higher antiknock value than gasoline alone and is more efficient. No increase in corrosion and lubricating-oil requirements was observed. Neither was any HOAc formed. Motor fuels with varying quantities of alc were investigated as to their power output. The required heat units per h. p. hr. diminish with increase in alc content, reaching a min. with about 20% of alc., and then steadily rise. With about 25% of alc. the power output is about the same as it is for gasoline. Thus it is not necessary to make any adjustments in the engine when the fuel is changed from gasoline to "Lättbentyl" and *vice versa*. Accidental addn. of H_2O to the latter had practically no effect upon it as a motor fuel even when it sepd into 2 layers; this phenomenon is probably due to the fact that the alc layer had retained a portion of the gasoline. Addn. of H_2O to gasoline, however, prevented locomotion until the water, collected in the carburetor, had evapd. In the winter, ice had formed in the fuel line and carburetor; no progress was made until the system had been sufficiently warmed to melt the ice, and the water removed. I. M. LEVINE

Low-temperature distillation. A. MAILHE. *J. usines gaz* **54**, 347-9(1930). Results of low- and high-temp distn. of 4 typical soft coals are compared from a practical standpoint. Distn. of 5-kg. samples below 500° gave gases of high calorific value, [illegible] to 1/4 those of high-temp. distn

converting heavy oils (50% of the tar) into motor fuels is the most [illegible] of low-temp. distn. Tar acids are abundant, but PhOH, economically the most important, occurs only in traces. K. H. ENGEL

Chemical and microscopical investigations of the coals from the Witbank and Ermelo coalfields. P. E. HALL. *J. Chem. Met. Mining Soc. S. Africa* **31**, 127-39 (1930); cf. *C. A.* **24**, 3198, 4374, 4915, 5133, 5969; **25**, 394.—Discussion. A. H. E

Analyses of Wyoming coals. Bur. Mines, *Tech. Paper* **484**, 159 pp.(1931).—**The Wyoming coal fields.** C. E. DOBBIN. *Ibid* 1-9.—Wyo. coal ranges from low-rank subbituminous to high-rank bituminous. **Methods of mining and preparation of coal.** E. H. DENNY. *Ibid* 10-12. **Production, distribution and use.** F. G. TRYON. *Ibid* 13-20.—Figures are given for production by counties and districts, coal loaded by machine, tons per man per day, amt. of coal prepd. by different types of screening equipment, shipments by sizes, uses, distribution and competition with other fields. **Relation of mine samples to commercial shipments.** N. H. SNYDER, L. N. PLEIN AND R. D. REEDER. *Ibid* 21-24. **Analyses of delivered coal.** N. H. SNYDER, L. N. PLEIN AND R. D. REEDER. *Ibid* 25-33.—Analyses are given of 125 samples. **Analyses of mine samples.** A. C. FIELDNER, H. M. COOPER AND F. D. OSGOOD. *Ibid* 35-77.—Analyses are given of about 550 samples. **Description of mine samples.** F. D. OSGOOD. *Ibid* 78-154. ALDEN H. EMERY

Recent developments in coal cleaning. R. LESSING. *Chemistry and Industry* 50, 84-7(1931); cf. *C. A.* **24**, 2268. E. H.

Washability studies of the Mary Lee bed at Hull Mine, Dora, Ala. B. M. BIRD, A. C. RICHARDSON AND G. D. COE. Bur. Mines, *Rept. of Investigations* **3067**, 24 pp.

(1931); cf. *C. A.* **24**, 3879.—The problem of washing the Mary Lee bed at the Hull mine is confined to ash reduction. A washed coal low enough in ash to permit its use in the manuf. of coke is not obtainable in the coarse sizes without recrushing to $^3/_{16}$ in. ALDEN H. EMERY

The constitution of coal. II. P. LEBEAU AND H. LEROUX. *Ann. combustibles liquides* **5**, 579–613(1930); cf. *C. A.* **25**, 795.—The results of the thermal fractionation of the various products obtained from the Durham coal are given in detail. E. S.

The new age of coal. Coal dust firing, production of oil and gasoline from coal. KARL BAY. *Teknisk Ukeblad* **75**, 115–8, 126–8(1928).—A review, considering particularly the importance of the Bergius process. C. A. ROBAK

Agglomeration of soft coals and the action of solvents. L. CRUSSARD. *J. usines gaz* **54**, 429–42(1930).—The action of C_5H_5N, PhOH, C_6H_6 and NaOH upon coal is discussed from a theoretical standpoint. The exts. contain those substances which cause agglomeration during the coking process. Generally, the less sol. (or the more complex) these bituminous exts. are, the greater is their agglomerating power. Not the total C_5H_5N ext., but rather the asphaltic bitumen content (petroleum ether-insol.) represents a measure of the coking tendency of coals. K. H. ENGEL

Coal storage in silos. O. O. WEHRMANN. *Gas u. Wasserfach* **73**, 1144–6(1930).—Two bituminous coals were stored in silos and the air was analyzed at intervals. The CO_2 began to appear only after 4 months, gradually reaching 0.2–0.4%, depending on the coal. No SO_2, CO or CH_4 was found. These expts. confirm the results of Grunenwald, who found that the elementary analysis of coal which had been stored in the open showed a decrease in the C content and a marked increase in the O and N content. Danger of damage to concrete silos by the sulfate content of water clinging to washed coals is mentioned. R. W. RYAN

Hydrogenation of coal and oil. OTTO HUPPERT. *Petroleum Z* **26**, 1250–1(1930).—Coal is liquefied by hydrogenation under high temps. and pressures with or without catalysts and indirectly by hydrogenation of CO obtained from coal. None of these processes is operated on a com. scale. Of the products formed, the heavy oils are used again in the coal-hydrogenation cycle, the middle oils are converted into gasoline by hydrogenation in the presence of catalysts, the character of which may be changed according to the product desired. In a similar manner petroleum distillates yield gasoline with practically no residue. A small quantity of gasoline is also obtained in the primary hydrogenation of coal. I. M. LEVINE

Low-temperature carbonization and hydrogenation of coals. J. F. GRAM. *Teknisk Ukeblad* **75**, 342–5(1928).—A review C. A. ROBAK

The peat problem in a new light. J. F. GRAM. *Teknisk Ukeblad* **76**, 13–6(1929).—A review. A new drying app. of Thomas Gram, which has a substantially better efficiency and economy than all formerly known app. for the drying of peat, is considered. The new app. is based upon the drying of previously air-dried peat with not more than 80% moisture, which is disintegrated and in powder form is blown through narrow outwardly heated vertical cylinders. In order to facilitate the disintegration, the air-dried product is first mixed with a suitable portion of dry peat. The drying is carried out in 2–4 steps according to the water content of the starting material, in order to improve the heat economy. **Reply.** J. G. THAULOW. *Ibid* 28–31.—T. agrees that the drying should be based upon air-dried peat as the raw material. Thus it is possible to produce a peat fuel on a profitable basis by means of other drying methods than that mentioned by Gram, often in connection with steam power plants heated with peat powder. C. A. ROBAK

Some chemical and chemical engineering problems associated with modern gas practice. R. S. ANDREWS. *Proc. Soc. Chem. Ind. Victoria* **30**, 414–22(1930).—The problems are discussed under the following headings: (1) the selection of the coal, (2) the compn. of coal gas, (3) gas dehydration, (4) recovery of by-products and (5) future development of the gas industry. In selecting coal it is generally agreed that a good gas coal should give a high yield of gas of definite B. t. u. and its coking properties should be such that a marketable coke may be produced. In the U. S., where most of the carbonizing plants are coke ovens because of the demand for metallurgical coke, good coke production is as important as gas production. Almost invariably a coal possessing marked swelling properties produces a dense, hard coke, and is suited to coke ovens but is unsuitable for vertical retorts because of its tendency to impede the travel of the coal through the retort. When coal is heated water and occluded gases are evolved up to 200° when a decompn. point is reached and water of constitution and oxides of C begin to appear. At 350° olefins are evolved and above 350° thick resinous oils. From 350° to 700° there is a rapid evolution of tar and gas. H_2 appears

in increasing amts. as the temp. is raised still higher. B. t. u. in the form of CH_4 are more useful to the consumer than B. t. u. in the form of styrene and indene, which form gummy deposits. In the dehydration of gas the preferred method is the use of a 40% soln. of $CaCl_2$. A problem of first magnitude in by-product recovery is the conversion of vertical retort tar into suitable road material. In England it is blended with horizontal retort and coke-oven tar. In Australia an attempt has been made to convert it by means of catalysts in an oxidizing atm., to polymerize the unsatd. substances, and also to form condensation products with tar acids and added aldehyde, *in situ*. Two thousand tons of this converted tar has been used successfully on roads. For NH_3 recovery the most commonly used method is to wash the NH_3 from the gas with water and steam-distill the ammoniacal liquor thus formed. The recovery of benzene is practically confined to the coke-oven industry. The usual practice is to scrub the benzene from the gas with creosote or paraffin oil in tower scrubbers or rotary washers, and then remove the benzene from the absorption oil by steam distn. Vertical retorts give a smaller yield of cyanides than horizontal retorts or coke ovens. There is a modern tendency toward complete gasification of coal in a single unit as a substitute for carbonization and water-gas production in sep. units. F. H. BERGEIM

Work of the gas appliance section of the German Gas Association. E. H. LUDWIG. *Gas u. Wasserfach* **73**, 1153–6(1930).—A discussion of gas meter and appliance standards, publicity, etc. R. W. RYAN

Slow combustion of ethane. WILLIAM A. BONE AND S. GERALD HILL. *Proc. Roy. Soc.* (London) **A129**, 434–57(1930).—The induction period is shortened or obliterated by the addn. of small quantities of moisture, EtOH, HCHO, I_2 or N_2O_4 to a dry $C_2H_6 + O_2$ medium, without altering the nonexplosive character of the ensuing combustion. Addn. of 1% of AcH vapor causes instantaneous inflammation of the medium. The reactivity of a $C_2H_6 + O_2$ mixt. is largely detd. by the relative C_2H_6 concn. Peroxidation and intermediately formed aldehydes seem to be the more probable cause of "knock." FRANK URBAN

Researches on purifying materials for acetylene. KIYOAKI SUMIYA AND SAKAI YAMADA. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding, 527–9, 530(1930).—The main impurities in C_2H_2 made from CaC_2 are PH_3, H_2S and NH_3. The standard purifying agent for comparison was colored acid earth with 10% HCl contg. 5% $HgCl_2$. "Acagin" (bleaching powder 85, Pb chromate 15), and "Puratylen" (bleaching powder 70, CaCl 20, CaO 10) purify C_2H_2 but introduce Cl. "Heratol" (compn. not given) purifies well and does not contaminate. "Catalysol," "Epurene" and "Booer's Purifying Material" were tested, the last being by far the most efficient, and regenerable by air. Addn. of a min. quantity of $HgCl_2$ to the material contg. infusorial earth and FeCl as the main ingredients accelerates the purifying activity of $FeCl_3$ on C_2H_2. When a small quantity of $CuCl_2$, $CuSO_4$, $Cu(OAc)_2$ or powd. Cu is added to the purifying mixt comprising mainly infusorial earth and $FeCl_3$ with a min. admixt. of $HgCl_2$, recovery of the once lost purifying power by the action of air is markedly accelerated. $Fe(OAc)_2$ acts similarly. E. M. SYMMES

Technical measurement supervision of Diesel engines. W. LIESEGANG. *Die Wärme* **53**, 966–9(1930).—The sepn. of the recording and indicating instruments, an advantage of elec. measuring processes, is desirable for Diesel operation. Resistance thermometers for oil temp. measurement, pyrometers for detn. of the flue gas temp. of each cylinder, flue gas analysis, and the estn. of oil consumption are discussed. ALLEN S. SMITH

The phenols of a primary tar of the Saar. J. PAIRA. *Ann. combustibles liquides* 5, 651–76(1930).—From a primary tar of a Saar coal the phenols were sepd. and the different fractions were extd. with NaOH and petroleum ether (cf. *C. A.* **24**, 3100). For the identification of the various phenols the *p*-nitrobenzoic and the hydroxyacetic acid

derivs. were used. The presence of ordinary phenol in the tar is definitely established. E. SCHOTTE

Continuous tar dehydration and light-oil removal at the Limoges gas works. A. CABRIER. *J. usines gaz* **54**, 368–9(1930).—Raw tar is circulated through 2 communicating columns. It enters the larger one, with storage capacity, and gravitates into the heating pot. The generated vapors propel the tar upward through an ejection syphon into the head of the large column, where water and oil vapors are taken off, the dried tar returning to its starting point to be recirculated until the proper road-tar specifications have been attained. A steam jet may be introduced into the heating chamber. The temp. of the vapors is not allowed to exceed 250°. The app. may be applied to the drying and reclaiming of wash oils, the concn. of NH_3 liquors, etc. K. H. ENGEL

Testing of creosote oils from coal tar. PONTIO AND GANDIN. *J. usines gaz* **54**, 181-2(1930).—See *C. A.* **24**, 3102. K. H. ENGEL

Some experiences with blast-furnace tar. A. JAQUES. *Chemistry & Industry* **49**, 1094–5(1930).—The Scotch furnace is the oldest low-temp. carbonization plant in operation. After sepn. from the ammoniacal liquor the tar is distd. and yields "virgin blast-furnace creosote oil," which begins to boil at 170°, and blast-furnace pitch. Mineral matter and pitchy material deposited from the tar while being carried out of the furnace along with the gas tend to foul the gas mains, necessitating periodical cleaning. To reduce the cost of cleaning the gas mains, a section of main was erected which was provided with sprays. After a few days' operation the tar in the reservoir tank suddenly boiled over. A lab. study of the polymerization showed that its speed increases rapidly as the temp. rises. Tar maintained at 100° gave 43% of oil when distd. to 320°, while tar maintained at 85° gave 58%. Untreated tar gave 61%, calcd. on the dry basis. The polymerization is exothermic. Blowing air through the tar during distn. reduced the oil production to 30–40%. A distn. plant erected at the Ab-der-Halden plant gave satisfaction and yielded oil, calcd. on the dry tar, to 55–60%, against an av. of 22% for the old stills. W. H. BOYNTON

Determination of phenols in coking-plant waters. A. TRAVERS AND AVENET. *J. usines gaz* **54**, 229–30(1930).—See *C. A.* **24**, 4919–20. K. H. ENGEL

Fuel. AUGUST HALLER (Oskar Neuss and A. Thieme, inventors). Ger 512,956, Jan. 19, 1929. $(CH_2)_6N_4$ is mixed with an inorg. or org. scorifying agent of low m. p., for use as fuel or heating material. In the example $(CH_2)_6N_4$ is mixed with powd. Na K tartrate.

Separating fuels, ores, etc., of differing specific gravities by tangential washing currents. SUSQUEHANNA COLLIERIES CO. Ger. 511,571, July 12, 1927.

Motor fuels. SOCIÉTÉ H/H OIL CO. AKTS. Fr. 691,430, Mar. 7, 1930. Aromatic hydrocarbons are treated with HNO_3, the liquid is allowed to stand and the acid decanted. The hydrocarbons are afterward treated with H_2SO_4, the excess removed and the product washed. Other or heavier hydrocarbons are added and the mixt. is distd. and satd. with O at the desired temp. Alc., the water of which is emulsified with salts favorable to combustion such as NH_4NO_3, and a fatty acid may be added to the fuel.

Solid fuel. REINOLD V. SMITH. U. S. 1,790,356, Jan. 27. A fuel suitable for briquetting under light pressure is formed of 76–84% of carbonaceous material such as coal together with gilsonite 2.5–9.0, water 5–8 and petroleum residue 8–13%. An arrangement of app. for prepg. the fuel is described.

Distillation of solid fuel. JEAN LIGER. Fr. 692,091, June 4, 1929. Solid fuel, particularly schists, is introduced in a finely ground condition and with about 1/3 of its wt. of inert material into a horizontal rotating chamber heated to about 500°. The materials are energetically stirred. Fr. 692,092 describes a similar furnace, a small proportion of inert material and a temp. of about 350° being used.

Destructive hydrogenation. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ Brit. 335,386, Nov. 7, 1928. The material designated as "luxmass," pretreated as described in Brit. 314,859 (*C. A.* **24**, 1493) and Brit. 335,513 and used as a catalyst in the destructive hydrogenation of coal or other carbonaceous materials, is rendered more efficient by mixing it with Mo or Mo compds. such as ferric molybdate. Brit. 335,513 relates to the obtainment of liquid or lower b. p. products from coal or other carbonaceous materials by heating under pressure in the presence of H and using, in one or more stages of the process, a catalyst obtained by dissolving "luxmass" (an alk. ferric hydroxide) so far as possible in HNO_3, pptg. with NH_3 and drying. Various details of procedure are given. Cf. *C. A.* **24**, 5983.

Destructive hydrogenation. H. W. STRONG and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 335,215, June 19, 1929. In the liquid-phase destructive hydrogenation of carbonaceous materials such as oils or suspensions of coal in oils, the catalyst employed is in the form of an extended solid metallic surface formed by the deposition of one metal on another, such as iron or mild steel coated with Sn or iron coated with Ni, the walls of the reaction vessel may be similarly coated. Catalysts such as tinned iron or steel are activated by a preliminary treatment which may remove part of the coating metal, as with a 5–10% HCl soln. or a 10% NaOH soln., and 5% of urea may be added to the acid soln. to form a surface layer of $Sn(OH)_2$ which is subsequently reduced in the course of the process; or the plates may be immersed in a bath of a molten salt such as Na metaphosphate or borax at 900–1000°; or tin plate may be heated for half an hr. or longer in a bath of oil or paraffin at 350° to effect alloying of most of the Sn with the Fe. The activated catalysts may be heated in moist H at 500° under pressures up to 500 atm. Brit. 335,216 describes the prepn. and use of similar catalysts. Brit. 335,217 relates to the use as catalysts of Sn alloys which are not molten at the reaction temp., such as alloys of Sn with Fe, Cu, Mg or P, which may be carried on a support of steel contg. Cr and Ni. Brit. 335,218 describes the combined use of massive and porous catalysts. The massive catalyst is preferably composed of at

least 2 metals such as iron coated with Sn or Ni, or a metal such as Sn and a metalloid such as As, Sb, Bi, Se or Te. As porous catalyst, bog iron ore, Fe_2O_3 or Fe_2O_3 contg. Al_2O_3 1–5% may be used on a support such as pumice or magnesia (the oxides being reduced by H before use as catalysts). The 2 catalysts may be used in the same or in sep. reaction vessels.

Apparatus for distilling carbonaceous materials at low temperatures. INTERNATIONAL HOLDING DE DISTILLATION ET COKÉ-FACTION À BASSE TEMPÉRATURE ET MINIÈRE (HOLCOBAMI). Fr. 691,832, Mar. 12, 1930. Cf. *C. A.* **24**, 5984.

Retorts for the low-temperature distillation of carbonaceous materials. THE CARLTON MAIN COLLIERY CO., LTD. Fr. 690,939, Feb. 27, 1930.

Carbonizing fuels. "CARLSHÜTTE" A.-G. FÜR EISENGIESSEREI UND MASCHINENBAU. Ger. 514,317, Jan. 20, 1925. See Brit. 283,259 (*C. A.* **22**, 3979).

Apparatus for carbonizing wood, peat, lignite, etc. SOC. ANON. "LA CARBONITE." Ger. 513,125, Feb. 23, 1926. Addn. to 439,884. The materials are dried, carbonized and cooled while packed in annular containers having impervious outer walls and perforated inner walls.

Swinging oven for low-temperature carbonization, with direct or partly direct heating. GEORG MERKEL. Ger. 514,010, Sept 9, 1928.

Vertical annular retort for low-temperature carbonization of coal. PHILIP CROSBY POPE. Ger. 513,202, April 11, 1929. See Brit. 309,387 (*C. A.* **24**, 713).

Apparatus for distilling coal, etc. FREDERICK DEACON MARSHALL. Ger. 513,124, Nov. 30, 1926. See Brit. 261,919 and 261,927 (*C. A.* **21**, 3493).

Retort for the distillation of coal. ILLINGWORTH CARBONIZATION CO., LTD. Ger. 511,588, Nov. 23, 1929

Coal distillation. WILHELM HECKEL (to C H. Ellsworth). U. S 1,789,549, Jan. 20 For producing products such as coke, low-temp. tar relatively free from naphthalene, oils of the aliphatic series having lubricating properties and a gas rich in hydrocarbons of the ethylene and paraffin series, the material is heated to not more than about 500° to cause distn of volatile products, and the distn. is continued at not to exceed 500° until the treatment is completed. Volatile products are withdrawn at not above 500° and are progressively cooled to successive cooling stages of about 135° in the first stage to cause condensation of one portion of low-temp. tar, 65° in the second stage to cause condensation of another portion of low-temp. tar, and 35° in a third stage to cause condensation of oils of lubricating properties, and the volatile products still remaining uncondensed are collected.

Refining coal. TELEX APPARATEBAU, G. M. B. H. Ger. 511,514, Sept. 1, 1922. App for removing dust from coal, etc., is described.

Experimental apparatus for investigating the coking of coal. C. OTTO & CO. G. M. B. H. (Wilhelm Schluter, inventor). Ger. 511,252, Mar. 15, 1928. This relates to app. of the kind comprising a horizontal refractory tube, closed at one end, which contains the sample of coal and is connected to absorbers for the distn. products. Improved elec. heating means for the tube is described, designed to ensure that the temp. conditions in the part of the tube traversed by the distn. products shall approx. to those in the upper part of a coking chamber.

Coking powdered coal. INTERNATIONAL COMBUSTION ENGINEERING CORP. Ger. 511,792, Feb. 28, 1926. Details of heating, drying and distg. the coal are given.

Cooler for lignite, etc. MASCHINENFABRIK BUCKAU R. WOLF A.-G. Ger. 514,339, Dec 16, 1928.

Tube drier for lignite, etc. VIKTOR KASPER. Ger. 511,723, Jan. 21, 1928.

Montan wax. HANS FRIEDLANDER. Ger. 512,823, Sept. 13, 1925. Crude montan wax is refined by heating to 170–270° and leading in an air current.

Gas. HUMPHREYS & GLASGOW, LTD. Fr. 690,798, Feb. 28, 1930. A mixt. of hydrocarbon and water gas is made in a plant comprising a vessel contg. a combustible gas in ignition, a vessel contg. a regenerative material and means for extg. tar. Steam is produced in the tar-extg. material and this steam is passed through the ignited mass. Cf. *C. A.* **25**, 1061–2.

Gas. HUMPHREYS & GLASGOW, LTD. Fr. 690,868, Mar. 1, 1930. A mixt. of hydrocarbon and water gas is made in a plant composed of 3 vessels, one contg. solid fuel and the other 2 being heat storers. The 2 heat-storing vessels are heated by internal combustion of the gas produced by blowing air into the 3rd, a hydrocarbon is introduced alternatively into one and then into the other of the heat-storing vessels and a part at least of the hydrocarbon gas is passed through the mass of fuel after extn. of tar.

Desulfuration of gases and vapors. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 335,394, Oct. 23, 1928. See Dutch 22,257 (*C. A.* 24, 5087).

Drying illuminating gases by filtration through fibrous material. ERNST CHUR. Ger. 512,827, Aug. 30, 1929.

Fuel gas. MATHILDE LOTZ NÉE BLICKLE, AUGUSTE LOTZ, ARTHUR LOTZ, MATHILDE SPANKE NÉE LOTZ, MARIA KOWSKY NÉE LOTZ, ROBERT LOTZ and WALTER LOTZ. Ger. 513,233, Jan. 24, 1928. This relates to the manuf. of fuel gas by gasifying coal and then treating the glowing coke with steam. The improvement consists in superposing a charge of fresh coal on the coke before passing in steam. App. is shown.

Measuring the calorific value of fuel gas. ALBERT HERBERHOLZ. Ger. 514,042, April 27, 1927. To det. the calorific value of the gas as supplied, the calorimeter reading is automatically influenced by measuring instruments, *e. g.*, a thermometer, a hygrometer, and a manometer, located in the gas main or at the place of use. The calorimeter may indicate simultaneously or alternately the calorific value of the gas reduced to standard conditions. App. is shown.

Apparatus for producing fuel gas by carbureting air. CHARLES PERDRISAT. Ger. 514,108, Jan. 6, 1929.

Means for withdrawing fuel-distillation gases from the lower part of vertical gasifying chambers. KURT BEUTHNER. Ger. 511,316, Jan. 4, 1929.

Combustible gas free from carbon monoxide obtained from coal. W. BERTELSMANN and A. C. BECKER. Brit. 335,228, March 18, 1929. CO is removed from coal gas (suitably in part by liquefaction under compression or by passage with steam over Fe oxide, Cr oxide, porous C or other catalyst, followed by conversion of the remaining CO into CH_4 by contact with Ni under pressure) and the sp. gr., heating value and speed of ignition of the gas are then restored by adding H, constituents of flue gas, etc. Various details of treatment are described.

Burning gas. HENRY C. CALDWELL (to Caldwell Experimental Corp.). U. S. 1,789,542, Jan. 20. Initial mixing of gas is effected with air in proportions sufficient for substantially complete combustion, in a refractory combustion chamber. App. is described.

Tower for air-cooling of waste furnace gases. O. OVERMANN. Brit. 335,299, July 10, 1929.

Catalytic treatment of gases emitted by internal-combustion engines. JOSEPH C. W. FRAZER. U. S. 1,789,812, Jan. 20. For eliminating combustible constituents such as CO, etc., from the products of emission of internal-combustion engines during their intermittent operation, a continuous uncooled stream of the products in the presence of O is subjected to the action of a catalyst comprising an artificially prepd. metallic chromate such as that of Fe or Zn. App. is described.

Oil-gas generating apparatus. FRANK J. NOLAN (to Thermo Industries, Inc.). U. S. 1,790,166, Jan. 27. Various details of construction are described.

Apparatus for generating water- or producer-gas. OSCAR NYGAARD and BENJAMIN H. SNOW (to Bernitz Furnace Appliance Co.). U. S. 1,790,110, Jan. 27. Various details of generator construction and operation are described.

Gas producer. C. OTTO & Co G. M B. H. Ger. 511,659, Sept. 28, 1927. Details of regulating the feed hole and air supply are given.

Gas producers. ZAHN & Co. G. M. B. H. Ger. 512,654, Dec. 19, 1928. App. for gasifying fuel such as lignite briquets is described.

Gas producer with horizontal or inclined chambers. INDUGAS INDUSTRIE- UND GASOFEN-BAUGES. M. B. H. Ger. 513,232, Mar. 21, 1929.

Gas producer with a jacket of upright tubes for producing steam. POETTER G. M. B. H. Ger. 511,660, July 13, 1929.

Water jacket for gas producer, with removable outer wall. GEBR. KÖRTING A.-G. Ger. 513,231, July 24, 1928.

Producer for making water gas from coal dust. GAS UND TEER G. M. B. H. (Hermann Hillebrand, inventor). Ger. 471,328, Aug. 25, 1927.

Control device for periodically operating gas producer. BAMAG-MEGUIN A.-G. Ger. 513,136, Oct. 28, 1928.

Suction-gas producer suitable for use on automobiles or boats. A. E. HODGSON, N. C. JONES and MOTOR OWNER'S PETROL COMBINE, LTD. Brit. 334,888, June 10, 1929. Structural features.

Gas retort for powdered fuel. ALBERT LEDEBUR. Ger. 511,658, Feb. 27, 1929. Addn. to 477,581 (*C. A.* 23, 4330). Details of construction are given.

Apparatus for removing dust from flue gases, etc. GOTTLOB BURKHARDT. Ger 475,436, Mar. 12, 1927.

Storing gases. SOCIÉTÉ SVENSKA AKTIEBOLAGET GASACCUMULATOR. Fr. 691,795, Mar. 12, 1930. Porous material for storing C_2H_2 and like gases under pressure is composed of cement and substances such as pumice, pumiceous tuff, trass and natural or artificial slags.

Storing acetylene. AUGUST CAPPEL. Ger. 511,304, Oct. 25, 1927. Porous org. materials, with or without pulverulent inorg. materials, that are to be used as fillers for vessels for storing C_2H_2, are impregnated with a soln. of animal or vegetable albumin, treated with a tanning soln. or vapor, and then dried.

"Waterless" gas holder. R. & J. DEMPSTER, LTD., N. H. KNIGHT, C. ANDREWS and WATERLESS GASHOLDER CO., LTD. Brit. 335,296, July 6, 1929.

Purifying coke-oven gases, etc. SOC. L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS GEORGES CLAUDE). Ger. 511,100, Oct. 17, 1924. See Brit. 224,863 (*C. A.* **19**, 1940).

Chamber-oven plant for producing gas and coke. C. OTTO & CO. G. M. B. H. Ger. 514,167, Jan. 5, 1930.

Oven for producing gas and coke, with horizontal chambers. C. OTTO & CO. G. M. B. H. Ger. 514,008, Oct. 6, 1928.

Device for straightening the chamber walls of ovens for producing gas and coke STETTINER CHAMOTTE-FABRIK VORM. DIDIER. Ger. 514,009, July 17, 1929.

Coke oven. HUGO SCHRÖDER. U. S. 1,790,597, Jan. 27.

Coke oven. C. OTTO & CO. G. M. B. H. Ger. 511,516, Dec. 18, 1926. Details.

Coke oven. C. OTTO & CO G. M. B. H. Ger. 511,805, July 31, 1929. Addn. to 502,903 (*C. A.* **24**, 5470) Details are given of an internally cooled device for expelling coke.

Multiple regenerative coke oven. HEINRICH KOPPERS A.-G. Ger. 512,797, Sept. 28, 1929. Details of construction are given.

Automatic closing device for horizontal coke ovens. N. V. SILICA EN OVENBOUW MIJ. Fr. 691,874, Mar. 13, 1930.

Apparatus for quenching coke to give steam free from acid or water gas. JOSEF KOY. Fr. 690,943, Feb. 27, 1930.

Coking. C. OTTO & CO. G. M. B. H. Ger. 511,563, Sept. 10, 1924. An upright chamber furnace for coking coal and simultaneously producing water gas by blowing steam through the hot coke is described.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

The petroleum situation in America. REPT. OF THE COMMITTEE ON PETROLEUM ECONOMICS TO THE FEDERAL OIL CONSERVATION BOARD, Nov. 6, 1930; *Mining J.* 171, 1011–3(1930).—The demand for gasoline for the 6 months ending March 31, 1931 will not exceed that of the yr. before and may be less. The industry is operating on a basis geared to a 7% increase in gasoline consumption. Reduction in operating rates is necessary. A curtailment of 7% from the Oct. rate of gasoline supply is necessary to balance a break-even demand if spring inventories are not to exceed 45 million bbls. If this is divided proportionally among the various sources (straight-run 47.3, cracked 37.1, natural 11.1, imports 4.0 and benzene 0.5%), then a crude run to stills of 2,310,000 bbls. per day and a domestic crude-oil production of 2,270,000 bbls. per day are indicated. This can be allocated as follows: Calif. 542, Okla. 542, Texas 730, and others 456 thousand bbls. daily. Should gasoline demand prove more adverse or curtailment be confined to straight-run operations, addnl. restrictions would be needed and tables are provided to cover these contingencies. ALDEN H. EMERY

Petroleum potentialities of Gulf Coast petroleum province of Texas and Louisiana. DONALD C. BARTON. *Bull. Am. Assoc. Petroleum Geol.* **14**, 1379–1400(1930).—The petroleum potentialities of the Texas-La. Gulf Coast area have been greatly increased in the last 3 yrs. Ultimate recovery will be at least 3.5 billion bbls., probably 5.5 billion and possibly 10 billion bbls. Increasing depth has been accompanied by increasing Baumé gravity of the oil. ALDEN H. EMERY

Oklahoma City oil field, Oklahoma. HOMER H. CHARLES. *Bull. Am. Assoc. Petroleum Geol.* **14**, 1515–33(1930).—Analyses of oil from the Arbuckle limestone and from the Simpson sand are given. ALDEN H. EMERY

Salt Flat oil field, Caldwell County, Texas. L. F. MCCOLLUM, C. J. CUNNINGHAM

AND S. O. BURFORD. *Bull. Am Assoc. Petroleum Geol.* **14**, 1401–23(1930).—The stratigraphy and structure of this field, the origin of the oil and its compn. are discussed.

EMMA E. CRANDAL

Does petroleum form in sediments at time of deposition? PARKER D. TRASK AND C. C. WU. *Bull. Am. Assoc. Petroleum Geol.* **14**, 1451–63(1930).—Chem. analyses of large quantities of recent marine sediments from 4 regions in which deposits rich in org. matter are now forming indicate that liquid petroleum probably does not occur in sediments at the time of their deposition The presence of small quantities of solid paraffins suggests that some normal constituents of petroleum occur in newly deposited sediments. The 3 marine samples contained 5% of org. matter and yielded 2 gals. of oil per ton. One sample is probably a mother rock of a rich oil shale, contg. 50% of org. matter and yielding 28 gals. of oil per ton. Fatty acids are normal constituents of the sediments, ranging from 2 to 6 parts per 100,000 in the marine and 16 parts in the lake sample. They are cerotic ($C_{26}H_{52}O_2$), montanic ($C_{28}H_{56}O_2$) and melissic ($C_{30}H_{60}O_2$) in all but one sample and caproic acid ($C_6H_{12}O_2$) in that. Fatty acids + hydrocarbons form about 0.04% of the sediment, < 1% of the org. content, seemingly inadequate to account for the petroleum Org. S compds. form about 30 parts per 100,000, pigments 5 parts, free S 22–104 parts and small quantities of sterols A. H. E

Hydrogenation of petroleum and its industrial importance. V. VALGIS. *Azerbaidzhanskoe Neftyanoe Khozyaistvo* **1930**, No 11, 4–15.—A historical review stating that Ipatiev has priority over Bergius in the hydrogenating processes V. K.

The modern large-scale distillation of petroleum. P. P. PRANDSTETTEN. *Petroleum Z* **26**, 1209–11(1930); *Oesterr. Chem- Ztg.* **34**, 2–7(1931).—A lecture I. M. L.

Highest vacuum in the mineral oil industry. E. HOFFMANN. *Petroleum Z* **26**, 1262–3(1930).—A process for distn of crude oil is discussed. The pressure is reduced to 0.5 mm. and the oil is heated by steam and hot-water coils, the temp. of which is maintained at 10–20° above the b. p. of the oil. The advantages of the process are (1) Because of the low distn temp., cracking of the oil is avoided, *e. g.*, the av. b. p. of a fraction is reduced from 455°F. at 40 mm to 260°F. at 0.5 mm (2) Practically no loss is sustained, because of the evenness with which the distn proceeds. (3) The residue is free from suspended matter. (4) The life of the plant is longer and the risk less because of the indirect method of heating I. M. LEVINE

Distillation of Ragusa shales. GIORGIO ROBERTI. *Atti III congresso naz. chim. pura applicata* **1930**, 533–9. Conditions of distn., yields and grades of oil produced are shown.
F. M. S

Distillation of oil shale. R. H. CROZIER. *Chem. Eng. Mining Rev.* **23**, 58–60(1930).—By means of the Crozier distn. process, Tasmanian oil shale yields 30–40 gal. of oil per ton. From the oil may be obtained gasoline, kerosene, Diesel, fuel or gas oil and pitch, all of which can be made marketable with a light refining treatment The equipment consists of a vertical retort, heated from the side with gas formed in the operation, and also by means of an ascending current of steam superheated by heat exchange with the bed of hot coke at the bottom of the retort. The shale is fed into the retort from the top; the vapors are continuously withdrawn as soon as they are formed and passed to the condensers, which are so constructed that the various fractions may be obtained without need of rerunning. The equipment may also be used for the *distn. of coal.*
I. M. LEVINE

The dressing of oil sands. K. KELLERMANN AND A. VOGT. *Petroleum Z.* **26**, 1141–8, 1157–64(1930). Of the oil in the sands only about 20% is brought to the surface. Since pure sand is a hydrophile and is wet by oil but very slowly, water should displace oil from the sand This does not occur unless the sand is wet with water before it is satd. with oil. Under these conditions only, does the addn. of water cause a clean sepn of the 3 phases With a sand freed from oil by extn. but not purified further, its relations to water and oil, resp., may be the reverse of those applying to meticulously pure sand. This less pure sand may be wet by oil and not by water The impurities are apparently capillary-active substances which would influence not only the solid-liquid but also the oil-water interfaces. This idea was tested in detail Oberg-Peine crude oil was fractionated both *in vacuo* and at atm. pressure. The interfacial tension between each fraction and varying concns. of Na_2CO_3 from 0.001 *N* to *N* was measured by means of a stalagmometer whereby the no. of oil drops was detd in a definite vol. It was assumed that the no. is inversely proportional to the inter

facial tension σ. σ decreased with increase in concn. of the Na_2CO_3 and generally with rise in the b. p. of the fraction. This indicates that the active substances are concd. in the higher-boiling fractions. Sapon. of these substances led to the formation of soaps which are not as capillary-active as the substances themselves; thus, σ is raised. This effect is aided by the decrease in concn. of the Na_2CO_3 due to sapon. Several instances are given in which the negative effects were greater than the positive, *i. e.*, σ increased with increase in b. p. That the lower-boiling fractions are devoid of capillary-active substances was shown by tests on C_5H_{12} and $(CH_2)_6$ and also by the fact that when the fractions were obtained by atm. distn. σ dropped to a min. and then rose sharply with the b. p. This reversal was due to the presence of low-boiling materials resulting from cracking, which was also evidenced by the high Br, I and O numbers, when compared with those of the corresponding fractions obtained in the vacuum distn. σ decreases with increase in temp., and theoretically vanishes at the crit. temp. The active substances are amphoteric as shown by the fact that dil. solns. of acids also decrease σ. The most effective material is NaOH, followed by H_2SO_4, HCl and Na_2CO_3. HOAc has a slight effect due to its low H-ion concn. and also to its soly. in both the oil and aq. layers. As a well-known corollary of the decrease in σ there is the adsorption of the active constituents in the interface. The Na_2CO_3, etc., was also thought to be concd. in the interface and its mols. orientated in such manner that the Na was closest to the oil surface. Cond. measurements before and after a Na_2CO_3 soln. was brought into contact with the crude oil fractions signified that there was a decrease of electrolyte in the body of the soln. Adsorption, like the decrease in σ, was affected by sapon. which was so great for Sumatra and Borneo oil, which are known to contain a quantity of saponifiable material that negative, values were obtained. The adsorption of Na_2CO_3 and capillary-active constituents in the interface should tend to make the oil and oil-satd. sand hydrophiles. If a mechanical force were now applied that would expose the surface of the sand to the aq. soln., the displacement of the oil would be effected. An expt. was conducted in which gas bubbles were relied upon to furnish this force. Oil-soaked sand was placed in a cylinder above a layer of $NaHCO_3$, and at 45°, CO_2 bubbles were formed. In a very short time oil drops 0.2–0.3 mm. in diam. rose through the aq. soln. and were lifted by the bubbles to which they were attached. The displacement was lively and in 2 hrs. the oil was completely sepd. from the sand. Attempts to accomplish the sepn. by contacting the sand with concd. solns. of $MgCl_2$, $CaCl_2$ and $BaCl_2$ failed. The oil sand was also subjected to a d. c. of 500 v. without any effect excepting that of oxidation and polymerization by the O liberated at the anode when water or a dil. soln. of an electrolyte was also added to the sand. I. M. LEVINE

Oil refining in the Soviet Union. S. S. SHIPMAN. *Refiner and Natural Gasoline Mfr.* 9, No. 10, 78(1930). J. L. ESSEX

Manufacture of low pour-point oils. E. R. LEDFRER AND E. W. ZUBLIN. *Refiner and Natural Gasoline Mfr.* **10,** No. 1, 73(1931).—The progress that has been made in dewaxing oils, including the latest solvent process, is discussed. J. L. ESSEX

Rectification of natural-gas hydrocarbons. I. N. BEALL. *Refiner and Natural Gasoline Mfr.* **9,** No. 12, 67(1930).—B. discusses the compn. of natural gases, the means for fractionating them into *n* fractions, selecting the proper no. of plates, the proper reflexing material, and the volatility index. The manuf. of liquefied petroleum gases as well as all the factors such as crit. temp. and pressure, uniformity of raw material, procedure, size of column and proper blending of gases are discussed fully. J. L. E.

Detonation characteristics of some paraffin hydrocarbons. W. G. LOVELL, JOHN M. CAMPBELL AND T. A. BOYD. *Ind. Eng. Chem.* **23,** 26-9(1931).—The relative knock ratings of 27 paraffin hydrocarbons in admixt. with gasoline have been detd. Upon the basis of mol. structure and the antiknock effect of $C_6H_5NH_2$ as a standard, it was found that, in homologous series, knocking increased with increase in the length of the C chain, while in isomeric series the knocking usually decreased as the no. of side chains increased and the successive introductions of CH_3 groups into a C chain of any given length also decreased the knock tendency by a substantial increment per CH_3 group. The $C_6H_5NH_2$ equiv. of 2,2,4-trimethylpentane (isooctane) is +16 and that of heptane is −14; the compression ratios for these 2 compds. were 6.9:1 and 2.75:1, resp. J. L. ESSEX

The formation of peroxides in the direct oxidation of hydrocarbons with air. P. MONDAIN-MONVAL AND B. QUANQUIN. *Compt. rend.* **191,** 299-301(1930); cf. *C. A.* **24,** 1512.—An oily yellow mixt. of peroxides is formed from C_6H_{12}, C_6H_{14}, C_7H_{16} or gasoline by oxidation with air at about 300°. By operating a few degrees below the temp. at which white fumes appear, 20-5 cc. is obtained from 70 g. of C_6H_{14}. The

mixt. may be vacuum-distd.; at 200° it decomposes exothermally with a blue luminescence but without flame to give CH_2O, other aldehydes and white fumes. When added to NaOH soln., it evolves H_2, and MeOH and HCOOH are found in the soln. CH_3OOH and probably its homologs are present. Formation of these peroxides may explain *knocking in motors*. A. F. SHEPARD

Cracking urged as answer to Europe's oil problems. PAUL TRUESDELL. *Refiner and Natural Gasoline Mfr.* 9, No. 10, 90(1930). J. L. ESSEX

Vapor-phase cracking in England. W. MCKECHNIE ROBSON. *Refiner and Natural Gasoline Mfr.* 9, No. 10, 73(1930). J. L. ESSEX

Italy is building an oil industry based on cracking. GUSTAV EGLOFF. *Refiner and Natural Gasoline Mfr.* 9, No. 10, 75(1930). J. L. ESSEX

The reaction mechanism for cracking. NIKOLAUS MAYER. *Petroleum Z.* 26, 1248–50(1930).—Gurvitch advanced the idea that under cracking conditions hydrocarbons undergo decompn. similar to the decompn. of $CaCO_3$ to CaO and CO_2, with the difference that cracking is momentarily nonreversible. M. asserts that the nonreversibility is of longer duration. In a manner analogous to the dissocn. of $(Ph_3C)_2$, hydrocarbons may dissoc. under the proper conditions into compds. in which C contains less than 4 valences, these compds. being stable under the conditions. By condensation and addn. these primary products may then be converted to other products, also more heat-resistant than the original compds. In agreement with this idea is the fact that the high-boiling fractions of a cracked product are more difficult to crack than are analogous fractions of a crude oil. In further analogy to the behavior of $(Ph_3C)_2$, the extent of the dissocn. of which depends upon the quantity of solvent used and on the temp., the cracking of hydrocarbons in the liquid phase is aided by the dissocn. effect of the liquid (solvent). Thus cracking should take place in the liquid phase at a lower temp. than that necessary for cracking in the vapor phase. The high pressure necessarily imposed upon the system to maintain the oil in the liquid phase at the cracking temp., would have the effect of increasing polymerization reactions The most favorable yield of gasoline should, therefore, result when the oil is brought to the cracking temp., the liquid phase being maintained, and then suddenly expanded by releasing the pressure. I. M. LEVINE

A new type of cracking process. GEORGE REID. *Refiner and Natural Gasoline Mfr.* 9, No. 11, 81(1930).—The Pratt vapor-phase process (cf. U. S. pat. no. 1,752,264, *C. A.* 24, 2594) is discussed. A 26° A. P. I. gr. Midcontinent topped crude oil produced 42% of 225° end point gasoline having a benzene equiv. of 80%, 38% of a 14° A. P. I. gr. cracked fuel oil, and 20% of coke, gas and loss. Three gal. of gasoline is recovered from each 1000 cu. ft. of gas. No cracking chamber or coke accumulator is used. J. L. ESSEX

Experimental cracking unit has interesting features. BRAD MILLS. *Refiner and Natural Gasoline Mfr.* 10, No. 1, 89(1931).—The *Hoge cracking process* is described. The reaction chamber contains baffles. The operating temp. is 540–680°, operating pressure is 2 lb. per sq. in. and vapor velocity is 900 ft. per min. Yields of 80% of gasoline are obtained from Kern County crude oil. J. L. ESSEX

Effect of time and temperature on the cracking of oils. J. C. GENIESSE AND RAYMOND REUTER. *Ind. Eng. Chem.* 22, 1274–9(1930).—Expts. in cracking a Midcontinent gas oil at atm. pressure indicated that the gasoline product was nearly the same in character whether the temp of cracking was low and the time long or the temp. high and the time short. The time for attaining a given result can be halved by raising the temp. 17°. EMMA E. CRANDAL

Cracking of California kerosene and stove oil at relatively low pressures. G. EGLOFF. *Petroleum Z.* 26, 1263–4(1930); cf. *C. A.* 24, 5472. I. M. LEVINE

Mexican kerosene cracked at 300 pounds gives good antiknock gasoline. GUSTAV EGLOFF AND E. F. NELSON. *Refiner and Natural Gasoline Mfr.* 9, No. 11, 77(1930).—See *C. A.* 25, 195. J. L. ESSEX

Natural gasoline in California. G. ROSS ROBERTSON. *Ind. Eng. Chem.* 22, 1268–73(1930).—The gasoline-absorption plant of the Los Nietos Producing and Refining Co. at Kettleman Hills utilizes a small portion of its stripped gas as fuel and for driving turbines which service the pumps. Some 90 billion B. t. u. are wasted daily in the gas which must be permitted to escape into the atm. The compact criss-cross system of heat exchange between the fat and lean absorption oil is so efficient that the diff. in temp. at the cold fat-oil end is only 20° F. EMMA E. CRANDAL

New natural gasoline specifications. ANON. *Refiner and Natural Gasoline Mfr.* 10, No. 1, 126(1931).—The basis for the new specifications is the Reid vapor pressure and the temps. at which 10%, 35% and 60% are evapd. The new requirements

are: vapor pressure of 10–34 lb. abs. per sq. in. at 37.8°, percent evapd. at 60°, 25–85; at 135° not less than 90, end point not over 191°, corrosion neg., Doctor test neg. and color not below 25 Saybolt. There shall also be 24 grades. The max. vapor pressure of the several grades is to be 14, 18, 22, 30 and 34 lb., resp., and the min. percent evapd. at 60°, 25, 40, 55 and 70. The grades shall be marked, for example, 22-25, indicating the pressure and percent evapd. The temp. of 60° must be corrected for barometric pressure at the rate of 0.55° for each 14 mm. difference in pressure. The reasons for adopting these specifications are set forth The specification becomes effective Jan. 1, 1932, but is optional from Jan. 1, 1931. J. L. Essex

Final Report of the Departmental Committee on ethyl gasoline. A. G. Francis, Dixon, R. A. Hepple, *et al. Ministry of Health, Gt. Britain* 91 pp.(1930); *U. S. Pub. Health Eng. Abstracts* **10**, IHS, 7(Dec. 6, 1930).—It is concluded that no public health reasons exist for prohibiting the use of *ethyl gasoline* in automobiles so long as reasonable precautions are taken. The recommended precautions include labeling the cans and pumps, and dyeing the gasoline which should not contain more than 1 part of PbEt in 1300 parts by vol., or about 1 in 650 by wt. A *new and accurate method of detecting the presence of small amts. of Pb* is described. By use of the method, the Pb in urine, dusts and in garages was deted. More Pb was found in crank-case oils in automobiles using ethyl gasoline. No amt. likely to create danger was found in lubricating oils, either as a result of spilling or from the exhaust gases in city traffic. By animal expts., the daily application of ethyl gasoline to the skin caused neither local irritation nor impairment of the general health. Only under the most exceptional circumstances is there any danger from ethyl gasoline exhaust gases in garages or on city streets. C. R. Fellers

The formation of gum in motor fuel. R. Brunschweig and L. Jacqué. *Compt. rend.* **191**, 1066–8(1930).—Two benzene motor fuels contg. olefins, one fuel (I) having received a higher degree of refining than the other (II), were exposed for a period of 4 months (*a*) to air in the dark, (*b*) to sunlight alone and (*c*) to sunlight and air. Air alone had very little effect on either the color or gum content (residue upon evapn. of 100 cc. of the oil). Sunlight alone caused an increase in the gum content from 3 to 42 mg. for I and from 1 to 47 mg. for II. Exposure to both air and light brought the gum content up to 430 and 147 mg., resp. A small quantity of resin adhered to the walls in the case of I. Under the same circumstances the gum content of a com. gasoline rose from 20 mg. after artificial aging to 927 mg. of dissolved and 392 mg. of pptd. gum. The following conclusions may be drawn: (*a*) the production of color and gum are interdependent; (*b*) a motor fuel stable under ordinary storage conditions may become unsuitable under a lengthy exposure to sunlight and air; (*c*) light-stability is not a rigorous test of the quality of a fuel. I. M. Levine

Disorders in the operation of motor vehicles and their connection with the motor oils used. Ernst W. Steinitz. *Petroleum Z.* **26**, *Motorenbetrieb und Maschinen-Schmierung* No. 11, 9–14(1930).—Disorders that occur in the operation of motor vehicles, namely, residues in the combustion chamber, gasoline line, valves and crank-case, crankcase dilution, knocking, loss in power and difficulty in starting are discussed and related to the properties of the motor fuel and lubricating oil used. I. M. Levine

A modern German commercial distillation unit in Baku. Hans Siebeneck. *Petroleum Z.* **26**, 1257–61(1930).—The distn. unit is described. The essential elements are a pipe still, set in a furnace, a vaporization chamber and 3 fractionating columns each furnished with coolers. Various fractions can be obtained directly. By means of heat exchangers the raw oil is heated to 140° before it enters the furnace. I. M. L.

Stabilization and recovery plant. L. S. Gregory. *Refiner and Natural Gasoline Mfr.* **9**, No. 11, 74(1930); cf. *C. A.* **24**, 5472.—The advantages and disadvantages of removing C_3H_8 and C_4H_{10} are set forth. For every 1% of C_3H_8 removed from a pressure distillate more than 3.5% of C_4H_{10} may be added without increasing the vapor pressure of the blend, giving a net increase of 2.5%. Because of the first cost and operating cost, C_4H_{10} should not be removed unless the treating and rerunning losses are excessive. Removal of C_3H_8 saves the evapn. losses only. A typical plant is described. J. L. Essex

Determination of hydrogen sulfide in refinery still gases. A. R. Scharnagel and A. W. Trusty. *Ind. Eng. Chem., Anal. Ed.* **3**, No. 1, 29(1931).—A modified method consisting in the absorption of the gas in 2 scrubbers, each contg. 100 cc. of 0.1 *N* Pb acetate, the second scrubber acting as an indicator for the complete satn. of the first. The soln. in the first scrubber is filtered and the unused Pb titrated with NH_4 molybdate soln.

Fractionation for absorption plants. I. N. Beall. *Refiner and Natural Gasoline Mfr.* 9, No. 11, 86(1930); cf. *C. A.* 24, 3893.—The principles involved in the design and operation of the fractionating column of an absorption plant are discussed from a math. and a graphical viewpoint. Such factors as volatility ratio, liquid and vapor flow, heat balance, reflux cooling, no. of plates and caps and spacing of plates are also discussed. J. L. Essex

Reclaiming absorption oil as aid to plant efficiency. C. D. Gard. *Refiner and Natural Gasoline Mfr.* 9, No. 12, 74(1930). Dirty absorption oil lowers the efficiency of absorption because of increased mol. wt., lower oil rate due to the presence of inert asphaltic particles and water content, it increases heating and pumping costs as the result of lower fluidity and higher sp. gr., gums up the heat exchangers, increases pressure drop, and causes premature shut down. G. maintains a clean oil by passing less than 0.2% of the whole through a steam still, although a rate of 1.0% is maintained for the first 2 weeks. The loss is only about 4 gal. per hr. for a 100,000 gal. circulation of lean oil per hr. For a plant of 10,000,000 cu. ft. of gas contg. 0.65 gal. of C_4H_{10} per 1000 cu. ft., the gasoline recovery per day will be increased 400 gals. and the steam consumption will not exceed 18 boiler horsepower. J. L. Essex

Determination of evaporation losses. G. W. Chenicek and W. G. Whitman. *Refiner and Natural Gasoline Mfr.* 9, No. 11, 115(1930). The application of the vapor pressure method for detg. evapn. losses in gasoline storage tanks shows that unprotected tanks lose about 0.25% per month and tanks equipped with breather bags lose only 0.03% per month. On displacement tests a loss of 0.05% is found for tanks having a standard roof and 0.004% for those with floating roofs. The samples may be collected at some distance and sent to the lab. for analysis without loss of accuracy. J. L. Essex

Catalytic reactions of organic sulfur compounds. Hugh S. Taylor. *Refiner and Natural Gasoline Mfr.* 9, No. 12, 83(1930). A general survey of the problem of the reactivity of S compds. in petroleum when brought into reaction in the presence of contact agents is given; it is assumed that the reactions are like those of compds. contg. O and N. The variations attributable to temp., pressure, catalyst and reacting gas are summarized and the importance of the type of S compd. treated, as d. to the ease and extent of removal, is shown. J. L. Essex

Action of alkali hydroxides on elementary sulfur and mercaptans dissolved in naphtha. V. Vesselovsky and V. Kalichevsky. *Ind. Eng. Chem.* 23, 181–4(1931). KOH and NaOH (anhyd. or dissolved in org. solvents relatively free from water) remove elementary S and mercaptans from their solns. in naphtha. KOH is particularly effective in removing S, and NaOH in removing mercaptans. On prolonged contact in the presence of air, S and mercaptans reappear in soln. in consequence of oxidation and hydrolysis of the sludge formed. V. Kalichevsky

A new apparatus for sweating of paraffin. Laboratories of the Koninklijke Shell Groep. *Petroleum Z.* 26, 1217–20(1930). I. M. Levine

The de Florez furnace. Paul F. Swanson. *Refiner and Natural Gasoline Mfr.* 9, No. 11, 69(1930). A good description of the up shot heater having a capacity of 45,000,000 B. t. u. per hr. and 5500 sq. ft. of surface is given. Even distribution of heat to all tubes and the utilization of the max. radiant heat energy of the products of combustion are accomplished by closer contact of the combustion gases and tubes. The furnace operates at 65–75% efficiency at an overall heat transfer of 6500 B. t. u. per hr. per sq. ft. of external tube surface. The excess air is 25%. This furnace is used in a vapor-phase cracking unit where temps. of 570° are required. J. L. E.

Flue gas for reducing fire hazards. A. E. Pew, Jr. *Refiner and Natural Gas Mfr.* 9, No. 12, 122(1930). Various methods are given for using flue gases in tanks and refinery equipment to exclude air or dilute to such a degree that explosive mixts. are not formed. This system also eliminates the danger of discharge from static or bound charges, spontaneous ignition of pyrophoric Fe and S corrosive compds. which are ignition agents in the presence of explosive atm. J. L. Essex

Fluorescence analysis of coal pitch and petroleum pitch, so-called bitumen. W. Teuscher. *Chem. Ztg.* 54, No. 102, 987(1930). cf. *C. A.* 24, 2053.—An easy and simple method is described for the detection of coal tar in bitumen by means of the Haitinger and Reich (*C. A.* 23, 4889). Bitumen in solvents like benzene, alc., acetone and benzine gives a red-blue color in ultra-violet light. Coal tar in the same solvents is green-blue. A mixt. of both bitumen and coal tar is green-blue. Julius Wilh.

Kir. Edmund Graefe and Rudolf Schreiter. *Petroleum Z.* 26, *Asphalt und Strassenbau* No. 11, 3–8(1930).—Previous work on the definition and geographical and geological occurrence of kir is reviewed. This substance may be considered a

local term for asphalt more or less associated with sand and silt. A sample of kir originating in the Baku district was investigated. It was of low ductility, soft and unhomogeneous, being mixed with some oil. It had an ash content of over 52%. Asphalt acids were isolated, existing in the kir both in the free state and as alk. earth soaps. It is suggested that the asphalt was formed as a result of oxidation by air, of a petroleum residue, remaining after the lighter portions had evapd. The oxidation led to the formation of both higher mol. wt. hydrocarbons and acids, part of which reacted with the inorg. material with which it was closely assocd. The material may be used locally for roofs and floors inside houses. I. M. LEVINE

Petroleum coke. F. L. WALLACE. *Refiner and Natural Gasoline Mfr.* **9**, No. 11, 103(1930). J. L. ESSEX

Lubricating oils. J. TAUSZ AND A. STAAB. *Petroleum Z.* **26**, 1117-24, 1129-40 (1930).—The effect of diln. on the viscosity and mol. wt. of a lubricating oil with an oil of low mol. wt. was studied with the end in view of the use of the results in the detn. of the value of an oil as a lubricant. Viscosity was expressed as a function of diln. by the equation, $\eta_{\text{diln. oil}} = \eta^{x}_{\text{undiln. oil}}$ (*A*). The change of viscosity with temp. was expressed by a similar equation, $\eta_t = \eta^{x}_{20}$ (*B*), where η_t and η_{20} are the viscosities at $t°$ and 20°, resp. The values of x in *A* and *B* decrease with increase in diln. and temp., resp., and, in general, with decrease in mol. wt. of the lubricating oil. Both values of x are higher for vegetable oils than for mineral oils. However, x_A gives a truer comparison of the values of 2 oils than does x_B. x_A expresses this difference, but x_B does not, since it is practically the same for both oils. The mol. wt. of the mineral oils decreased with increase in diln. The decrease of both viscosity and mol. wt. with diln. signifies that the oil is dissocd. by the solvent. On the other hand, the mol. wts. of vegetable oils increase with increase in diln. although the viscosities change in the opposite direction. The explanation is offered that the dissocn. produced by the diluent is counteracted by solvation of the oil. The vol. change upon diln. of castor oil and Mobiloil by $C_{10}H_{18}$ and C_6H_6 was also detd. While in $C_{10}H_{18}$ the vol. increase is small for both oils but greater for castor oil, in C_6H_6, the vol. increase for Mobiloil is very large, while for castor oil there is a small increase up to the 50% point and then a decrease. The η in centipoises at 20°, of the following compds. is given: C_5H_{12} 0.2344, C_5H_{12} 0.3701, C_7H_{16} 0.5115, C_8H_{18} 0.6515, PhMe 0.5880, $C_6H_4Me_2$ 0.6560, cyclohexane 0.9765, methylcyclohexane 0.7202, $C_{16}H_{32}$ 2.3490, $C_{16}H_{18}$ 2.6920. I. M. LEVINE

Chemical structure of lubricating oils. G. H. B. DAVIS AND E. N. MCALLISTER. *Ind. Eng. Chem.* **22**, 1326-9(1930).—Evidence has been found supporting the view that Pennsylvania *lubricating oil melts* are a combination of *naphthene rings* and paraffin chains. The no. of C atoms that are in naphthene rings in a mol., N, can be calcd. from the formula $N = 0.358$ mol. wt. $+ 7.7 - 0.3$ mol. vol. This was verified experimentally on narrow fractions of a Pennsylvania lubricating oil by calcg. mol. formulas from the values of N and comparing them with the results of elementary analysis. The viscosity index, an index of the change in viscosity of an oil with temp. (cf. *C. A.* **24**, 5761), is also proportional to the percentage of the C atoms that are in naphthene rings. EMMA E. CRANDAL

The acid treatment of lubricating distillates. H. M. WEIR, W. F. HOUGHTON AND F. M. MAJEWSKI. *Ind. Eng. Chem.* **22**, 1298-1300(1930). The effects of varying the H_2SO_4 treatment of Solar reduced oil as to concn. and quantity of acid used and as to temp. of treatment, upon gravity, color, n and viscosity are reported. There is reason to believe that the action of H_2SO_4 is mainly phys. rather than chem. The following are probably the changes caused by the acid: (1) the formation of indicator-like substances, (2) the flocculation and absorption of (colloidally ?) dissolved bitumens, (3) soln. of other color substances contg. chromophores, (4) some sulfonation and oxidation. EMMA E. CRANDAL

Machine elements and the elements of lubricating technic. ERICH KADMER. *Petroleum Z.* **26**, *Motorenbetrieb und Maschinen-Schmierung* No. 11, 3-6(1930). I. M. LEVINE

The lubrication of ball and roller bearings in the steel mill. D. E. BATESOTE. *Iron Steel Eng.* **8**, 8-12(1931).—The rapidly growing use of antifriction bearings in the steel mill and particularly the introduction of such bearings in new and hitherto untried fields of application has made the problem of bearing lubrication a most important one. A good general lubricant specification called for by one large user of ball and roller bearings is: free acid, nil; neutral saponifiable, 1.0%; free alkali, 0.1%; S, 0.03%; resin, nil; ash, 1.5%; moisture, 2.0%; and abrasive particles, nil. The frequency and methods of lubricating ball and roller bearings are discussed, also methods of sealing against oil leakage. Numerous illustrations are included. W. H. B.

Detonation as affected by mineral lubricating oils. R. O. KING AND H. MOSS. *Engineering* **131**, 1–4(1931); cf. *C. A.* **24**, 5996.—Tests to det. the deleterious effect of various mineral lubricating oils on the antiknock properties of motor fuels with and without antidetonants show that the results depend on the particular mineral oil, the blend of motor fuel, the antidetonant (if used), and the induction temp. The deleterious effect increases directly with the compression ratio at which the fuel can be used, the effect being nearly independent of the compn. of the fuel, except that within a certain range fuels contg. naphthenes are less affected by oil than are fuels contg. aromatics. With doped fuels the effect seems to be on the metallic dope content, since the action of ethyl fluid increases to a max., then decreases in spite of increases in compression ratio. D. F. BROWN

The purification of used compressor oils. L. PIATTI. *Petroleum Z.* **26**, *Motorenbetrieb und Maschinen-Schmierung* No. 11, 7(1930).—The lubricating oil used in gas compressors contains $C_{10}H_8$ and H_2S. The impurities are sepd. by steam distn., the steam being admitted after the oil has been heated to 120°. The reclaimed oil has practically the same viscosity, flash and flame point as the fresh oil. The sp. gr., however, is high. I. M. LEVIN

Treating petroleum oil containing mercaptans. HERBERT G. M. FISCHER and WM. J. ADDEMS (to Standard Oil Development Co.). U. S. 1,789,335, Jan. 20. The oil is agitated with preformed PbS, NaOH and S in sufficient amount to convert the mercaptans into polysulfides.

Petroleum distillation control. WARREN K. LEWIS (to Standard Oil Development Co.). U. S. 1,789,339, Jan. 20. For controlling the lowest-boiling constituents of bottoms obtained in fractional distn. of petroleum oils, a minor part of the bottoms to be controlled is continuously abstracted at a substantially uniform rate and heated under conditions of substantially uniform heat input to produce vapor and an unvaporized residuum, the vapor thus produced is rectified, the temp. of the rectified vapor is measured and the conditions of the first distn. are modified as may be necessary to hold such temp. near a predetd. point. App. is described.

Separating paraffin from petroleum oils. JULES VERNER (to Standard Oil Development Co.). U S. 1,789,347, Jan. 20. A mixt. of oil carrying suspended paraffin is forced through a combined filtering and sweating zone to form first a filtrate and a layer of slack-wax in this zone, the filtrate is conducted away, and heat is then applied to the slack-wax *in situ* in the same zone sufficient to produce a liquid phase and a residuum of paraffin, the liquid phase is conducted away, and the paraffin is afterward melted and conducted away. App. is described. Cf. *C. A.* **24,** 3637.

Removing gum-forming compounds from cracked petroleum distillates. RUDOLPH C. OSTERSTROM, JULIUS HYMAN and CARY R. WAGNER (to Pure Oil Co.). U. S. 1,789,413, Jan. 20. The distillates are vaporized in the presence of polymerized compds. contg. Na sulfonates to accelerate the polymerization of the gum-forming compds. in the vaporized distillates, and the light desirable oils are then sepd. and condensed separately from the polymerized compds. An arrangement of app. is described.

Preventing gum formation in hydrocarbon materials. WM. S. CALCOTT and IRA E. LEE (to E. I. du Pont de Nemours & Co.). U. S. 1,789,302, Jan. 20. An acyl deriv. of an aromatic amine such as acetanilide is added to a petroleum distillate fuel such as gasoline.

Dephlegmating tower suitable for treating hydrocarbon vapors. WALTER M. CROSS (to Gasoline Products Co.). U. S. 1,789,670, Jan. 20.

Recovering sulfur dioxide in its use as liquid for treating hydrocarbon materials. JOHN C. BLACK. U. S. 1,789,510, Jan. 20. Sepd products from liquid-SO_2 treatment are subjected, in sep. containers, to a pressure distn. at a temp. sufficient to cause the major portion of the SO_2 to vaporize and the SO_2 is sepd., condensed and collected under the same pressure; the remainder of the SO_2 still retained by the hydrocarbon products is then vaporized, condensed and collected in an oil cooled to the liquefying temp. of SO_2 at the pressure employed (the last-mentioned distn. is conducted at 10 lb. gage pressure or lower). An arrangement of app. is described.

Cracking hydrocarbons. SIGBERT SEELIG. Fr. 690,661, Feb. 25, 1930. A mixt. of hydrocarbons is heated in a cracking zone and sepd. in an evaporator into vapor and liquid, the mixt. being projected and pulverized on to heating tubes traversing the evaporator.

Cracking hydrocarbons. SINCLAIR REFINING CO. Fr. 691,739, Mar. 11, 1930. For the manuf. of gasoline a current of oil of high b. p. is heated to a high cracking temp. under a low pressure and the hot products from this operation are introduced into a coking retort; a current of oil of higher b. p. is heated to a lower cracking temp. under a higher pressure and the hot products of this operation are transferred to the coking retort after reduction of the pressure; the mixt. of hot vapors from the coking retort is transferred to the interior of a liquid mass of oil contained in a washing vessel, below the surface of the oil; a fraction of oil from this liquid mass is supplied to the coking retort in which, conjointly with the non-vaporized components of the hot products from the distinct heating operations, it is reduced to coke; the hot vapors from the washing vessel are transferred successively by a primary and a secondary fractionation, a fraction of high b. p. in the second fractionation being used for the heating at low pressure, and a fraction from the primary fractionation being used for the higher pressure heating, both referred to above. A gasoline fraction is also obtained from the secondary fractionation.

Cracking oils. ANGLO-PERSIAN OIL CO., LTD. Ger. 511,133, May 17, 1928. See Brit. 293,889 (*C. A.* **23,** 1748).

Expansion valve for use in cracking oils under pressure. CARBUROL A.-G. Ger. 514,263, Oct. 1, 1927.

Heating hydrocarbon oils. POWER SPECIALTY CO. Ger. 514,262, April 29, 1927. See Brit. 283,032 (*C. A.* **22**, 3983).

Distilling heavy hydrocarbon oils. ALEXANDER S. KNOWLES (to Tar and Petroleum Process Co.). U. S. 1,789,312, Jan. 20. Material to be treated, such as tar, is deposited upon the upper portion of a loose porous bed of material, such as carbonaceous material, exposed to extraneous heat from below and held in a rotatable basket, and residual liquid is continually drained from the bed. Various details of app. and procedure are described. Cf. *C. A.* **24**, 950.

Decolorizing hydrocarbon oils and residues. N.-V. MIJNBOUW- EN CULTUURMAATSCHAPPIJ BOETON. Brit. 334,833, Jan. 30, 1929. "Cracked petrol" or other materials are decolorized by treatment at substantially atm. temp. with a 58% or stronger aq. soln. of one or more hygroscopic heavy metal chlorides such as $ZnCl_2$ or $FeCl_3$ or both. The treatment may be effected in stages with the use of successively stronger solns., and after sepn. from the treating soln the material may be neutralized and distd. and fractionated. The aq. soln. may be sepd. from polymerization products, concd. and reused. Further refining of the products, such as "white spirit" and kerosene fractions, may be effected at a temp. above 60° with a concd. soln. of chloride such as that of Fe, Cu, Ni, Al or Zn, or dark-brown lubricating oil may be similarly treated at 35°.

Refining mineral oils. ARTHUR LACHMAN (to Richfield Oil Co. of Calif.). U. S. 1,790,622, Jan. 27. Vapor of an oil such as gasoline is passed through, or in contact with, a maintained aq soln. of $ZnCl_2$ and then condensed. App. is described.

Lubricating oils. I. G. FARBENIND. A.-G. (Wilhelm Pungs and Erich Frese, inventors). Ger. 511,963, June 26, 1927. See U. S. 1,787,951 (*C. A.* **25**, 810).

Purifying light oils derived from coal gas. A. R. ALBRIGHT (to Koppers Co.) Brit. 335,155, Oct. 10, 1928. In the acid-alk. phenate purification of light oils extd. from coal gas, the phenolate soln. used is obtained by washing with alkali soln. the liquid or gas used to remove phenols from the ammoniacal gas liquor, a 7% H_2SO_4 and about equal proportions of NaOH and NaOPh being suitable. The phenols may be recovered by treating the used washing liquid with $NaHCO_3$ or CO_2.

Tank and baffle for separating oil and gas. JAY P. WALKER (40% to Guy O. Marchant and 6% to C. G. Wells). U. S. 1,789,612, and U. S. 1,789,613, Jan. 20. U. S. 1,789,716 and U. S. 1,789,717 also relate to generally similar app. for the same purpose.

Extracting benzene hydrocarbons from gases. FRITZ BREITBACH (to the firm of Carl Still). U. S. 1,790,571, Jan. 27. In treating gases such as distn. gases with wash oil contg. naphthalene, the benzene-charged wash oil is distd. to obtain a liquid distillate contg. naphthalene, the distillate is continuously rectified, and the liquid naphthalene-contg. residue from the rectification is returned while still warm to the main stream of wash oil circulating through the gas-scrubbing plant. An arrangement of app. is described.

Unsaturated hydrocarbons from mixtures such as oil-cracking effluents. HAROLD S. DAVIS (to Petroleum Chemical Corp.). U. S. 1,790,519, Jan. 27. Mixts. such as products from oil cracking contg. hydrocarbons having secondary and tertiary base structures are subjected to hydrohalogenation in a cold aq. soln. of a hydrohalogen such as HCl which is maintained at substantially const. satn. and the resulting hydrohalogenated derivs. of the hydrocarbons of tertiary base structure are sepd. from the unchanged hydrocarbons of secondary base structure by fractional distn.

Amylenes and butylenes from oil cracking. HAROLD S. DAVIS and WALLACE J. MURRAY (to Petroleum Chemical Corp.). U. S. 1,790,522, Jan. 27. A fraction is segregated from products of oil cracking contg. over 80% of unsatd. hydrocarbons including amylenes and butylenes and substantially free of C compds. of lower mol. wt. than C_3H_6.

Secondary alcohols from olefins produced in cracking petroleum oils. HAROLD S. DAVIS and WALLACE J. MURRAY (to Petroleum Chemical Corp.). U. S. 1,790,517, Jan. 27. For producing secondary alcs. with 4 and 5 C atoms to the mol., an olefinic fraction is sepd. from the cracked products consisting predominantly of secondary and tertiary olefins of the same no. of C atoms per mol. as the alcs. to be produced, tertiary olefins are removed from the fraction (suitably by use of 60-65% strength H_2SO_4) and the remaining secondary olefins are sulfated with aq. H_2SO_4 of suitable concn. and temp. and the sulfated material may then be used for obtaining alcs. U. S. 1,790,518 (HAROLD S. DAVIS) describes converting butylenes of cracked petroleum into secondary and

tertiary alc. by absorbing the butylenes under pressure in a mixt. of liquid olefins b. under 100° and treating the mixt. under pressure with H_2SO_4 of about 65% strength at a temp. below 30° and then treating with acid of over 70% concn. and allowing the temp. to rise to 35–45°.

Secondary amyl alcohol from olefins produced in oil cracking. HAROLD S. DAVIS and WALLACE J. MURRAY (to Petroleum Chemical Corp.). U. S. 1,790,523, Jan. 27. By fractional distn. of products from oil cracking there is obtained a fraction consisting predominantly of secondary and tertiary olefins of 5 C atoms per mol., tertiary olefins are removed from this fraction (suitably by H_2SO_4 of 60–65% strength) and the secondary olefins are sulfated with aq. H_2SO_4 of suitable concn. and temp. and the sulfation product is used for alc. production.

Secondary alkyl sulfates from olefins produced by oil cracking. HAROLD S. DAVIS (to Petroleum Chemical Corp.). U. S. 1,790,520, Jan. 27. Olefinic material consisting predominantly of secondary and tertiary olefins of not over 6 C atoms per mol. are hydrochlorinated with HCl of such concn. and temp. as will selectively convert the tertiary olefins into HCl addn. products, unchanged hydrocarbons are sepd. from the reaction products (suitably by fractional distn.) and the secondary olefins in the unchanged hydrocarbon constituents are sulfated with aq. H_2SO_4 of suitable concn. and temp.

Esters of organic acids and olefins. HAROLD S. DAVIS and CHARLES G. HARFORD (to Petroleum Chemical Corp.). U. S. 1,790,521, Jan. 27. Tertiary olefins are selectively removed from a mixt. of tertiary and secondary olefins produced in oil cracking and the remaining hydrocarbon mixt. is esterified with an org. acid such as HOAc in the presence of a catalyst such as H_2SO_4.

Rectifying gasoline such as that derived from natural gas. NATHANIEL E. LOOMIS (to Standard Oil Development Co.). U. S. 1,789,470, Jan. 20. Constituents for gasoline production are absorbed from a gas such as natural gas or still gas in a miscible absorbent such as oil and the resulting soln. is passed into, and downwardly through, a vapor and liquid contact tower, the lower end of which is heated, and there is passed downwardly through the upper portion of the tower a second relatively cool liquid such as fresh absorption oil which is substantially non-volatile under the prevailing conditions and adapted to absorb constituents less volatile than propane desired to be retained in the tower, and the vapors are withdrawn An arrangement of app. is described

Motor fuel. WILLARD C. ASBURY (to The Standard Oil Development Co.). Can. 308,408, Feb. 3, 1931. Low-boiling oils are produced from heavier hydrocarbon oils by destructive hydrogenation in the liquid phase at pressures in excess of 100 atm. and temps. 750–925°F. The fractions thus formed are sepd. and the fraction of intermediate b. p. is treated in the vapor phase with H under a pressure of 100 atm. at 925–950° F., whereby it is converted largely into low-boiling aromatic oil.

Motor fuel. STANDARD OIL CO. (an Indiana Corp.). Fr. 691,931, Mar. 14, 1930. A small proportion (0.05%) of an aminophenol compd. such as methylaminophenol or benzylaminophenol is added to the product obtained by cracking a hydrocarbon fuel in the vapor state to prevent the formation of gum or resinous products.

Lubricants. ALOX CHEMICAL CORP. Brit. 335,152, Dec. 18, 1928. Lubricants for machinery cutting tools and molds comprise a lubricating oil together with oxidation products such as those which may be derived from waxes from shale or brown coal or petroleum or heavy petroleum distillates as described in Brit. 303,560 (*C. A.* **23**, 4593) or Brit. 309,382 (*C. A.* **24**, 718). Various details and examples are given. Cf (*C. A.* **24**, 4928.

Lubricants. JULIEN MILLE. Fr. 692,289, Mar. 19, 1930. A mixt. of S, graphite and chlorophyll is added to an ordinary lubricating oil to prevent heating of machinery. An example contains oil 68, flowers of S 7, graphite 14 and chlorophyll 11%.

Lubricant. OLE ROLFSEN. Norw. 46,533, June 3, 1929. Glycerides of fatty acids of marine origin are introduced into mineral oil in which has been dissolved a product obtained by incomplete hardening of oils from whale, seal or other marine mammals.

Lubricant for combustion motors. OLE ROLFSEN. Norw. 45,365, July 16, 1928. Mineral oil is mixed with marine fatty oils which have previously been treated with H_2SO_4, dried and filtered.

Lubricant for gears. STANLEY D. WHITE and CARL L. KNOPF (to Sinclair Refining Co.). U. S. 1,789,614, Jan. 20. A lubricant is described comprising an oxidized blend of light lubricating oil, heavy flux oil and Na soaps of petroleum acids substantially free from water, having a MacMichael viscosity of 70–85 poises at 38° and a

Knopf viscidity not exceeding 12 oz. at about —18°. App. for testing viscidity and adhesiveness of oils is described.

Lubricating textile machine bearings. ARMAN E. BECKER (to Standard Oil Development Co.). U. S. 1,789,331, Jan. 20. Parts of machinery which may come into contact with the textile product are lubricated with a petroleum oil having a viscosity of about 50 to 250 sec. Saybolt at 38° to which has been added about 0.15 to 1.5% of a water-sol. alkali metal soap.

Lubricating oil. COPPERIZED STEEL, LTD. Ger. 512,056, Jan. 19, 1926. Metal parts which are subjected to high-temps. under non-oxidizing conditions are lubricated by applying in the cold a mineral oil having an asphaltic base. The subsequent heating of the parts then results in the production of an adherent carbonaceous lubricating layer.

Lubricating oils. STANDARD OIL CO. (an Indiana Corp.). Fr. 690,966, Mar. 1, 1930. A lubricating oil is made by polymerizing unsatd. hydrocarbons resulting from the cracking of hydrocarbon materials, which contain a much higher percentage of normal paraffin hydrocarbons than does distd. Pennsylvania oil. $AlCl_3$ may be used as polymerizing agent. Examples of temps. and proportions are given.

Heating lubricating oils with phenol. REGINALD K. STRATFORD (to The Standard Oil Development Co.). Can. 308,405, Feb. 3, 1931. Lubricating oil is agitated with 100–150% of undild. liquid phenol at a temp. not above 140°F. in one of a series of agitators. An oil layer and a phenol layer are sepd. and the phenol layer is transferred into the next agitator in contact with another oil layer according to the counter-current principle. The sepd. oil layer is submitted to distn. to remove absorbed phenol.

Purifying and using waste oils. CHARLES A. É. POULAT. Fr. 692,325, Mar. 20, 1930. Waste oil from motors is mixed with an equal vol. of gasoline, petroleum or other fuel used. An inert powder is added to the liquid which is filtered and added to the fuel used in the proportion of about 1–3%. Anticarbon products such as PhNO, or antiknock products such as CCl_4 may be added before or after filtering.

Bituminous compositions. MARCEL BOUTIN. Fr. 692,138, June 8, 1929. A bituminous or asphaltic compn. for use as a mastic, etc., is made by mixing a bituminous, etc., emulsion with a powd. mineral substance such as a siliceous material and stabilizing the mixt. by simple heating.

Apparatus for determining the shear-resistant qualities of bituminous mixtures. HUGH W. SKIDMORE and GENE ABSON (to Chicago Paving Laboratory, Inc.). U. S. 1,789,846, Jan. 20.

Mixing apparatus for making emulsions such as those of asphalt or heavy hydrocarbon oils. MAXWELL G. GREGG (to Flintkote Co.). U. S. 1,789,897, Jan. 20. Structural features.

Apparatus for mixing materials such as ingredients of asphalt emulsions. FREDERICK C. OVERBURY (to Flintkote Co.). U. S. 1,789,320, Jan. 20. Structural features.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Peptization and coagulation of nitro- and acetyl-cellulose. A. YA. DRINBERG. *Zhur. Prikladnoi Khim.* 3, 915–50(1930).—Peptization and coagulation of nitro- and acetyl-cellulose depend on concn., dispersing medium, degree of depolymerization of the cellulose ester and temp. V. KALICHEVSKY

The relation of temperature to viscosity of cellulose ester solutions. II. P. KARRER, E. BERL AND H. UMSTÄTTER. *Z. physik. Chem.*, Abt. A, 152, 150–2(1931). The same equation which has been found to hold for solns. of rubber is now found to hold for these ester solns. The fluidity is a function of the ln of the temp. V. F. HARRINGTON

The physical and chemical nature of nitrocellulose. A. BECK, L. CLÉMENT AND C. RIVIÈRE. *Chimie & industrie* 24, 1068–72(1930).—An acetone soln. of nitrocellulose was fractionated (1) by addn. of successive amts. of Me_2CO contg. 20% H_2O, (2) by evapn. *in vacuo*. In each case the viscosity and N content of each fraction were detd., and in each case it was found that the viscosity decreased in successive fractions, but that the N content was the same for all fractions as for the original nitrocellulose. It is concluded that nitrocellulose is chemically homogeneous but physically heterogeneous. A. PAPINEAU-COUTURE

The structure of celluloid. J. J. TRILLAT. *Compt. rend.* **191**, 654–6(1930).—The addn. of 5% camphor to a nitrocellulose film decreases the intensity of the internal x-ray diffraction rings; these completely disappear when the film contains 10–15% of camphor. At the same time, the external halo becomes more intense and its diam. decreases as the camphor content increases. The rate of decrease is rapid with the first 20% of camphor added, after which the curve slowly tends to approach the value for camphor alone. No evidence of crystn. is found in ratios of camphor to nitrocellulose as high as 3 to 1. T. suggests the formation of a camphor-nitrocellulose combination of the nature of a solvate. At higher camphor concn. the complex dissolves in excess camphor, forming a solid solution. J. G. MCNALLY

Methods for distinguishing between viscose and cuprammonium rayon. R. GEIER. *Textile Forsch.* **12**, 1–3(1930); *Chimie & industrie* **24**, 1183(1930).—Viscose is scarcely colored by direct dyes at 20°, while cuprammonium rayon is dyed deeply. Dyeing 2 min. at 20° in presence of Na_2SO_4 is sufficient to give a difference in shades satisfactory for distinguishing between the two. Viscose which has been previously treated with soda has much more affinity for the dyes, but even in this case the dyeing must be carried out considerably above 20° to give as deep shades as are obtained on cuprammonium rayon. A. PAPINEAU-COUTURE

Rayon waste and staple fiber prospects for 1931. E. W. DUTTON. *Rayon* **12**, No. 1, 22–4(1931). CHAS. E. MULLIN

Wood grinding and modern grinding apparatus. TRYGVE KITTELSEN. *Teknisk Ukeblad* **75**, 476–8(1928).—A review. C. A. ROBAK

The modern paper industry of Canada. WESSEL WAAL. *Tek. Ukeblad* **75**, 321–3 (1928).—A review. C. A. ROBAK

Oak chips from tan-works as raw material for paper. V. NERECHTSKII. *Bumazhnaya Prom.* **1929**, No. 2/3; *Zellstoff u. Papier* **9**, 835–6(1929).—Waste chips may be used for the manuf. of cellulose, but the bark, which cannot be removed after the lixiviation process, is detrimental to the properties and quality of the pulp. Oak wood contains 5–6.5% of tanning material, of which the heartwood contains 82%, the sapwood 2% and the bark 16%. By de-barking the wood and removing the sapwood before extn. and improved tannin ext. is obtained. The sapwood can then be used for the manuf. of cellulose, while a second tanning ext. can be obtained from the bark; the residue of the latter serves as fuel. Alternatively, the bark can be burned without extn., thus giving an increased yield of heat. De-barked, lixiviated waste chips give 51.3% of unbleached cellulose or 46.1% of bleached material; this corresponds to 27.7% on the original wood. The unbleached pulp may be used for the manuf. of packing papers, the price of which is lower than that of similar papers from straw cellulose The properties of such papers and of pasteboards made from waste-chip cellulose are also superior to those of corresponding materials from straw cellulose. For the economical conversion of the waste chips into paper the lixiviation and paper works should have a common steam-power plant. B. C. A.

Chinchin's sizing process (for paper). A. MARTYEMIANOV. *Zellstoff u. Papier* **9**, 838–9(1929).—Papers of different kinds were sized by the usual process, in which the necessary ingredients, pulp, filling, rosin, alumina, etc., were simultaneously mixed together before beating, and by Chinchin's method, in which softened water was used and the alumina was added 30–40 min. after admixture of the rosin milk with the other ingredients. In the latter case, 41.6–50% saving of rosin and 27–33% saving of alumina were effected. This behavior is similar to that found for the Delthirna process. The most satisfactory results were obtained by the use of a size contg. 50–4% of combined rosin. The superiority of Chinchin's process is demonstrated by a comparison of the rosin and alumina consumptions on a price basis. B. C. A.

Cellulose. GÉRARD DE BARTILLAT. Fr. 692,105, June 5, 1929. Cellulose is obtained by the action of a soln. of SO_2 or salts or solns. of salts in which SO_2 enters into combination (sulfites, bisulfites, etc.) on wood in an autoclave heated from 100° to 110° at a pressure of 20–25 atm. Catalysts such as Pb, Al or their oxides may be added to the soln.

Cellulose. SOCIÉTÉ CHIMIQUE DES USINES DU RHÔNE. Ger. 511,793, Feb. 10, 1925. Cellulose is acylated in the presence of a solvent for the end product, in a rotary cylinder of large capacity. Globes or rollers may be fitted in the cylinder to work up the viscous mass. Cf. *C. A.* **24**, 2882.

Cellulose. I. G FARBENIND. A. G. (Max Hagedorn and Georg Hingst, inventors). Ger. 511,978, Nov. 2, 1927. A moldable substratum for films, etc., consists of water-resisting cellulose derivs. having in the mol., a fatty acid residue contg. more than 10 C atoms. Cellulose stearate and cellulose acetate laurate are mentioned in the examples. Cf. *C. A.* **24**, 5156

Cellulose. VEREIN FÜR CHEMISCHE INDUSTRIE A.-G. (Karl Werner and Roland Runkel, inventors). Ger. 512,958, Apr 16, 1926. Acetylcellulose is deacidified in fibrous or curdy form by treatment with aq. alc. and pressing. The app. is described

Cellulose. CHEM. FAB. POTI & CO (Ferdinand Schoeller, inventor). Ger 514,083, Aug. 26, 1926. Lignin and other incrusting substances are removed from cellulosic materials by means of aq. solns. of chlorinated aromatic sulfonic acids, with or without hydrocarbons, alcs or ketones Thus, unbleachable sulfite cellulose may be boiled with an aq. soln. of chlorinated isopropyl-β-naphthalenesulfonic acid. Chlorinated sulfonic acids of tetrahydronaphthalene and of the anthracene or phenanthrene series may also be used.

Cellulose from cottonseed hulls. BELA DORNER U. S. 1,789,354, Jan. 20. For recovery of filamentous material from them, cottonseed hulls are sufficiently dried to render them brittle, then subjected to moist air for a time only sufficient to allow the filamentous material to reabsorb moisture without restoring any substantial moisture content to the hulls themselves, the brittle hulls are chopped up or ground into particles without disrupting the filamentous material, and the latter is sepd. and recovered, and may be used for paper manuf

Production of cellulose. HAGB. HANSEN. Norw. 45,426, Dec 31, 1928 Cellulose-contg. material together with the boiling liquid is passed continuously through a number of digesters, being subjected to boiling in each of them.

High α-cellulose fiber. GEORGE A RICHTER (to Brown Co.). U. S 1,790,170, Jan. 27. Predigested wood pulp is digested in fresh alk liquor contg Na compds such as NaOH or Na_2CO_3 and sufficient spent liquor from the digestion is mixed with spent kraft liquor to make up Na losses suffered in the kraft digesting cycle, and Na constituents are recovered from the spent mixed liquors. Cf. *C. A.* **24**, 1218.

Alkali cellulose. I. G. FARBENIND. A.-G. (Fritz Melms, inventor). Ger. 513, 203, Mar. 8, 1929. A band of cellulose is drawn through a drying chamber and an alkalizing bath; the product is then pressed between rollers, the pressure applied by the rollers being kept const by automatically adjusting the gap between them according to the thickness of the cellulose band A product of uniform compn. is thus obtained App. is shown.

Apparatus for making tubes of regenerated cellulose. KALLE & CO. A.-G. (Julius Voss and Arthur Schade, inventors). Ger. 513,241, Feb. 24, 1928, and 513,242, April 18, 1929, addn. to 513,241.

Cellulose esters. I. G. FARBENIND. A.-G. (Max Hagedorn and EugenGuhring, inventors). Ger. 514,150, Oct. 27, 1926. Cellulose esters of inorg. acids are prepd by the reaction of alkali cellulose with inorg. acid chlorides. Examples are given.

Solvents for cellulose esters. Soc. KODAK PATHÉ (SOC. ANON. FRANÇAISE). Fr. 692,051, Mar. 17, 1930. A solvent for mixed cellulose esters contg. an α-hydroxy, α-ketonic or γ-ketonic acid radical and sol. in acetone or its homologs or in a 50–70%

aq. soln. of alc., consists of a mixt. of ethylene chloride and an aliphatic monohydroxy alc. contg. 1–5 atoms of C.

Cellulose esters and ethers. I. G. FARBENIND. A.-G. (Max Hagedorn, Otto Reichert and Eugen Gühring, inventors). Ger. 511,208, May 2, 1926. Mixed cellulose esters or cellulose ether-esters are prepd. by treating a cellulose ester or a water-insol. cellulose ether contg. reactive OH groups with acid chlorides. The ester or ether is used in soln. or swollen in an org. solvent, and an acid-binding agent may be present. The treatment of cellulose esters with chlorides of higher fatty acids is disclaimed. Examples are given describing the prepn. of an acetate-phosphate, a nitrate-benzoate, and a laurate-phosphate of cellulose, and of a silicate and a phosphate of ethylcellulose. The products may be used for making filaments, films and lacquers. Cf. *C. A.* **25**, 1083.

Cellulose esters and ethers. WOLFF & CO. KOM.-GES. AUF AKTIEN and HANS SCHULZ. Ger. 511,020, Jan. 26, 1927. Addn. to 440,844. According to Ger. 440,844, cellulose esters and ethers and artificial materials made therefrom are purified and stabilized by boiling with water under pressure, after first removing gases occluded in the materials by boiling with water at atm. pressure, or by steaming, or by a vacuum treatment at atm. or raised temp. This method is now modified by omitting the preliminary treatment, the gases being removed, during the pressure treatment, by passing steam or a gas through the aq. suspension.

Cellulose ethers. I. G. FARBENIND. A.-G. (Hans Henecka and Eduard Dörr, inventors). Ger. 511,019, Oct. 11, 1927. See Brit. 321,651 (*C. A.* **24**, 2882).

Cellulose ether compositions. HORACE H. HOPKINS and JOHN B. SEGUR (to Canadian Industries, Ltd.). Can. 308,108, Jan. 27, 1931. A cellulose ether compn. comprises rosin ester, linseed oil, butyl lactate, butyl alcohol and gasoline. Cf. *C. A.* **24**, 960.

Cellulose acetate. I. G. FARBENIND. A.-G. (Hans O. Hartlein, inventor). Ger. 513,363, Dec. 3, 1927. In acetylating cellulose with the use of H_2SO_4 and $ZnCl_2$ together as catalysts, the production of a product giving turbid solns. is avoided by adding to the mixt. a little HCl or a substance yielding HCl. An example is given.

Cellulose acetate. KODAK-PATHÉ (SOC. ANON. FRANÇAISE). Fr. 692,365, Mar. 20, 1930. Cellulose acetate is made by treating cellulosic material with the vapor of Ac_2O, following which the vapor of AcOH liberated by the acetylation is maintained in contact with the material until it is acetylated. The air is preferably removed from the reaction space before commencing the reaction. The product retains the original fibrous structure and is sol. in $CHCl_3$ when the reaction is pushed to the end. Cf. *C. A.* **25**, 1082.

Cellulose acetate. SOC. DISPERSOID FRANÇAIS. Fr. 692,106, June 5, 1929. Cellulose which has been reduced to the colloidal state is acetylated in a non-solvent medium.

Furfural; saccharifying cellulose. GUSTAV GANZ. Austrian 119,956, June 15, 1930. Cellulosic materials are treated with acid in two stages, the conditions in the 2 stages favoring, resp., the production of furfural and saccharification. Thus, the first stage may comprise treatment with H_2SO_4 of 4–5% concn. under 1 atm. steam pressure, whereby the pentosans are converted into pentoses, which are extd. and worked up separately to furfural. Or the first stage may be conducted under a higher pressure, e. g., 5 atm., whereby furfural is produced directly and may be removed by steam distn. In each event, the cellulosic residue is saccharified by heating with H_2SO_4 of 0.5–1% concn. under a pressure of at least 10 atm. An example is given.

Filaments, films, etc., from cellulose derivatives. H. DREYFUS. Brit. 334,853, May 31, 1929. In the coagulation incident to their formation or as an after-treatment, products such as those formed from cellulose acetate solns. or similar cellulose esters or cellulose ethers are treated with an "organo-mineral acid" of a concn. of 20% or high (suitably 30–50% or even the pure acid in some cases) such as methyl- or ethylenesulfonic acids, 1,2- or 1,3-propanedisulfonic acid, sulfoacetic acid, sulfosuccinic acid, ethanolsulfonic acid, α-toluenesulfonic acid, benzenesulfonic acid, phenolsulfonic and disulfonic acids, sulfosalicylic acid, sulfophthalic acid, naphthalene- and naphtholsulfonic acids, dimethylphosphinic acid and nitrophenylphosphonic acid. Various solvents may be present, and after the treatment the acid is preferably removed from the material by washing with water or an alk. soln. such as NH_3 soln. The temp. of treatment may range from 0° to atm. temp. or somewhat higher, and substantial hydrolysis of cellulose esters treated is preferably avoided. Various details and examples are given, and the treatment may be applied to mixed products contg. cotton, etc.

Cellulose derivatives and products resembling cork. I. G. FARBENIND. A.-G. (Max Hagedorn, inventor). Ger. 513,061, Nov. 9, 1927. See Brit. 300,207 (*C. A.* **23**, 3573).

Waste celluloid. WILHELM SATOR. Fr. 692,012, Mar. 15, 1930. Waste celluloid is regenerated by dissolving it in acetone, adding trichloroethylene, and removing the acetone by distn., whereby the nitrocellulose is pptd. The camphor dissolved in the trichloroethylene is recovered by a steam distn.

Plastic celluloid-like masses. I. G. FARBENIND. A.-G. (Gerhard Balle and Kurt Sponsel, inventors). Ger. 512,912, June 10, 1925. Nitrocellulose, sol. methylcellulose and camphor are worked up above 16°. High-boiling, non-volatile alc. may be added.

Viscose. I. G. FARBENIND. A.-G. (Wilhelm Eller, Karl Marx, Richard Hofstadt and Karl Brodersen, inventors). Ger. 512,896, Oct. 4, 1927. Viscose is pptd. in a bath contg. sulfonic acids, H_2SO_4 and sulfates. The sulfonic acids present are obtained by sulfonating mineral oil, especially brown-coal-tar oil, with oleum or $ClHSO_3$. Examples are given. Cf. *C. A.* 24, 239.

Viscose. I. G. FARBENIND. A.-G. (Adolf Kämpf, inventor). Ger. 512,897, July 21, 1928. Viscose is spun with a mixt. of mineral acid and salts, and nitrogenous aromatic sulfonic acids in which the N is present in bridging or side chains. Examples of such acids are diphenylaminedisulfonic acid, dibenzylaminedisulfonic acid, dimethyl anilinesulfonic acid, etc.

Gear-wheel pump for forcing viscose solutions to spinning nozzles, etc. W KIMMIG and M. HÖLKEN, GES. Brit. 335,091, Oct. 26, 1929. Structural features.

Artificial silk. ALGEMEENE KUNSTZIJDE UNIE N.-V. Ger. 512,592, April 21, 1929. The $MgSO_4$ concn. in H_2SO_4 of viscose pptg. baths is maintained const. by addn of the necessary amt. of $MgCO_3$ and the equiv. amt. of H_2SO_4.

Artificial silk. FABRIQUE DE SOIE ARTIFICIELLE DE TOMASZOW. Fr. 690,795, Feb 28, 1930. Artificial silk is made by adding compds. of B such as H_3BO_3 or borax, if necessary in combination with fats or free fatty acids, alcs., invert sugar or hydrocarbons, to collodion, acetate, viscose or other starting material for making silk or to the half made products

Artificial silk bands. VEREINIGTE GLANZSTOFF-FABRIKEN A.-G. Ger. 513,376, Jan. 8, 1928. Small bands of artificial silk having a width from 8 to 20 times their thickness are prepd. by spinning aq. solns of cellulose contg. a carbonate, particularly viscose contg. Na_2CO_3, into acid pptg. baths under such conditions of delayed coagulation that hollow filaments are first produced which collapse before they are completely coagulated, with the result that their uncoagulated inner walls unite An example is given.

Artificial silk, films, etc. HENRY DREYFUS. Fr. 690,772, Feb. 27, 1930. Silk, films, etc., are made by extruding solns. of cellulose derivs., particularly the acetate into mineral acids, *e. g.*, H_2SO_4 of 30–50%, or concd. acid esters. The extrusions may first pass through the usual coagulating bath. Cf. *C. A.* 25, 1084.

Artificial filaments, films, etc. BRITISH CELANESE, LTD., R. P. ROBERTS, R. I. R. DEAN and L. W. GREGORY. Brit. 334,838, May 9, 1929. Solns. such as an acetone soln of cellulose acetate or other suitable soln. of an org. cellulose deriv. are extruded into coagulation baths consisting of strong solns. of inorg. acids such as H_2SO_4, HCl or H_3PO_4 or into solns. of acid esters of inorg. acids such as ethylsulfuric acid or mono- or di ethylphosphoric acid, or the process may be modified by effecting extrusion into any suitable coagulation bath and then conducting the products into a bath contg. an acid ester of an inorg. acid The coagulated products are preferably given an "air run" and then washed to remove acidic substances. Various examples and details of procedure are given.

Artificial filaments. ACETA G. M. B. H. Ger. 513,375, May 2, 1928. Artificial filaments are prepd. from cellulose esters or ethers with the use of aq. pptg. baths contg. salts having a swelling action on the cellulose deriv., and also colloidal substances such as molasses, sol. starch, albumins or degraded keratin. The baths may include also other salts and org. solvents or swelling agents for the cellulose deriv. Examples are given.

Washing and treating artificial silk. I. G. FARBENIND. A.-G. Fr. 692,362, Mar. 20, 1930. Spinning cakes of artificial silk are washed and treated on tubular perforated supports, alternatively or simultaneously with a sprinkling and immersion in water or treating liquids. Cf. *C. A.* 25, 1084.

Washing and treating artificial silk. I. G. FARBENIND. A.-G. Fr. 692,001, Mar. 15, 1930. Cakes of artificial silk produced on centrifugal machines are washed and treated by causing the washing and treating liquids to traverse under pressure from the interior of the cakes solidly assembled in rows on horizontal perforated tubes which may be rotatable.

Spinning pumps for artificial silk. FREDERIC MCINTYRE. Fr. 691,843, Mar. 13, 1930.

Centrifuge for spinning artificial silk. BERLIN-KARLSRUHER INDUSTRIEWERKE A.-G. Brit. 335,307, July 16, 1929.

Centrifugal spinning pot for production or treatment of artificial textile threads, etc. J. L. RUSHTON, H. HILL and D. L. PELLATT. Brit. 335,049, Sept. 11, 1929. Structural features.

Apparatus for producing artificial-silk filaments from solutions such as those of cellulose acetate by the dry-spinning method. FRANK SHEDDEN, ALBERT E. DELPH and NOEL G. BAGULEY (to Courtaulds, Ltd.). U. S. 1,790,599, Jan. 27. Various details for regulating a supply of gas for control of operating conditions are described.

Treating waste liquors from soda or sulfate pulp manufacture. E. L. RINMAN. Brit. 335,371, July 15, 1929. Waste liquors are treated with oxides or hydroxides of Ba or Sr or both, preferably mixed with those of Ca, Mg, Al, Zn or Fe, before dry distn., and neutral substances such as C powder or alk. earth carbonates may be added. The product is preferably evapd. to a non-sintered mass below 150°, crushed and then fed through a distn. furnace heated to 600–700° at one end and 200° at the other end (steam at 500° being introduced into the hotter end), and the distillate thus formed may comprise *MeOH, acetone, Me Et ketone, acetone oil, other heavy oils and H*, contaminated with mercaptans and sulfides if sulfate lyes are used. Soda may be recovered from the distn. residue, and various details of procedure are given.

Fibers from potatoes. AMELIA UBBELOHDE NÉE POPPE. Ger. 514,298, July 17, 1928. Addn. to 460,837. Ger. 460,837 describes the manuf. of fibers, *useful in making paper*, from the residual pulp obtained in extg. starch from potatoes. The pulp is heated until it gelatinizes and is then allowed to ferment at about 30° until the fibers have settled out. The fibers are then cleaned by subaqueous sifting and flotation. App. is shown. This method is now modified by gelatinizing the pulp while it is in motion, e. g., on a heated traveling band.

Separating pith and fiber of cornstalks. ELTON R. DARLING (to Cornstalk Product Co.). U. S. 1,790,001, Jan. 27. Mech. features, involving beating, cleansing and subdividing the stalks, conveying under spray lines of water to a container, sepn. and removal to a sep. container of the fiber. A paper-making pulp is obtained.

Parchment-paper stock from cornstalk pith. ELTON R. DARLING (to Cornstalk Products Co.). U. S. 1,790,002, Jan. 27. The cleansed pith is digested in water under heat and pressure to sep. the pith into fibrous and non-fibrous constituents, the fibrous constituents are filtered off, the pithy constituents are bleached, and the pith is hydrated by agitation with water at a temp. of about 57°.

Cooking cellulose. EINAR MORTERUD. Norw. 45,641, June 24, 1929. The charge of raw chips after being introduced into the digester is swelled by application of hot, or superheated, liquid, preferably water or used cooking liquor, which is afterward tapped off. The pressure in the digester is reduced before or during the following introduction of the boiling liquid.

Defibering apparatus for cellulose and similar fibrous materials. KRISTIAN HOLTER and OLAF ØVILLER. Norw. 47,301, Dec. 16, 1929.

Sorting apparatus for cellulose and mechanical wood pulp. AKTIESELSKAPET THUNES MEK. VERKSTED. Norw. 47,217, Nov. 18, 1929.

Sorting apparatus for wood pulp. JOHAN HANSEN. Norw. 46,389, April 22, 1929.

Wood pulp. DONALD E. CABLE (to Oxford Paper Co.). U. S. 1,790,260, Jan. 27. Material such as wood chips is subjected to the digestive action of a reagent such as a bisulfite soln. under an initial "pentration-boosting pressure" of a non-oxidizing gas such as N which is permanently gaseous at ordinary temp. and pressure and is not substantially absorbed in the digestive process.

Regulating the concentration of paper pulps or other substances suspended in liquids. TORSTEN KÄLLE. U. S. 1,789,386, Jan. 20. There is imparted to the material to be regulated a forward rotary movement and the moving material is constrained to actuate an impulse member (by direct impact action in the case of higher concns. and by impact action effected by a rotary movement in the case of lower concns.) and this impulse member (of an app. details of which are described) sets in operation devices by which the concn. of the material is controlled. Cf. *C. A.* 24, 1911.

Apparatus for regulating the consistency of the pulp in pulp and paper mills. OSCAR OLSSON and ØISTEIN MEIDELL. Norw. 47,282, Dec. 9, 1929. Mech. features.

Cellulose digester with direct heating. EINAR MORTERUD. Norw. 47,043, Oct. 14, 1929. A number of sep. inlets for the heating steam are placed in several levels upward along the cylindrical middle part of the vessel.

Digester for sulfite cellulose boiling with forced circulation of the liquid. EINAR MORTERUD. Norw. 47,005, Oct. 7, 1929.

Apparatus for charging cellulose digesters. T. F. CHRISTIANSEN. Norw. 46,349, April 8, 1929.

Reversible circulation of the liquor in cellulose digesters. EINAR MORTERUD. Norw. 45,642, Oct. 1, 1928. A reversible pump is installed in the interior of the digester.

Discharging cellulose digesters. EINAR MORTERUD. Norw. 45,855, Nov. 26, 1928. Mech. features.

Waste gases from cellulose digesters. METALLGESELLSCHAFT A.-G. Ger. 512,957, May 31, 1927. Addn. to 437,531. Waste gases from cellulose digesters are cooled by stages to give water, water-oil emulsion, oil and leave SO_2. The lay-out of the plant is indicated.

Apparatus for the dewatering of cellulose and mechanical wood pulp. JULIUS STEPHANSEN. Norw. 45,375 and 45,376, July 16, 1928.

Strainers for cellulose and wood pulp. SVERRE THUNE. Norw. 45,818, Nov. 12, 1928. The straining sheets are made from aluminum or an Al alloy, for instance, duralumin.

Bleaching cellulose and other fibrous materials. CARL B. THORNE. Norw. 46,572, June 10, 1929. The bleaching is carried out in towers in a continuous process, without stirring of the pulp. The concn. of the pulp is high, about 18–25%.

Treating cellulose and paper pulp in screw-presses. KRISTIAN HOLTER and OLAF QVILLER. Norw. 46,023, Jan. 21, 1929. Air, steam, water or other washing liquids are applied to the mass in the pressing app. after the mass has passed the pressing screw, in order to attain an efficient washing out of boiling liquid and bleaching liquid in connection with the pressing process. The washing liquid is introduced through the hollow shaft of the pressing screw.

Containers of cellulosic or fibrous material. DUNLOP RUBBER CO., LTD., D. F. TWISS, G. W. TROBRIDGE and W. G. GORHAM. Brit. 335,271, June 25, 1929. The containers are provided with protective coatings by treatment with rubber or similar vegetable resinous materials in the form of aq. emulsions or dispersions in admixt. with an aq. dispersion of one or more waxes, and such usual rubber compounding ingredients as are of harmless character may be added.

Paper. LOUIS P. SCHWEITZER. U. S. 1,789,452, Jan. 20. For continuously measuring and controlling the wt. per area of the paper produced, a web formed of stock contg. excess water is treated, first mechanically and then thermally, gradually to diminish its water content, and the elec. resistance of a predetd. area of the web is continuously measured, across the width of the web, at that crit. stage of treatment where the remaining water is no longer mechanically removable, in order to effect proper control of pulp concn. An arrangement of app. is described.

Paper. HANS MEYER G. M. B. H. Ger. 511,769, Jan. 3, 1929. Details are given of discharging and washing out cellulose digesters.

Paper. I. G. FARBENIND. A.-G. (Arthur Franz, inventor). Ger. 512,927, May 22, 1927. Vegetable fibers are disintegrated by a soln. contg. chlorate, $HClO_3$ and a small quantity of HCl as catalyzer. Cf. *C. A.* **25**, 1085.

Paper. PAPIERFABRIKEN IN FRIEDLAND PAUL BARTSCH KOMM.-GES. Ger. 514,331, Mar. 29, 1928. A patterned paper is manufd. by craping the moist sheet, stretching, drying and satining. The pattern formed by the craping persists.

Paper making. HERVEY G. CRAM and ROY V. WELDON (to Great Northern Paper Co.). U. S. 1,789,515, Jan. 20. Mech. features.

Paper-making apparatus. ALONZO ALDRICH. U. S. 1,790,082, Jan. 27. Structural features.

Paper-making apparatus. AUSTIN E. COFRIN. U. S. 1,790,536, Jan. 27. Structural features.

Paper-making apparatus. E. VON ASTEN. Brit. 335,376, Sept. 30, 1929. Structural features.

Apparatus employing water jets for severing torn portions of the web on a paper-making apparatus. N. A. JACOBSEN. Brit. 335,143, Jan. 25, 1929.

Suction roll for paper-making apparatus. WM. H. MILLSPAUGH (to Paper & Textile Machinery Co.). U. S. 1,789,445, Jan. 20. Structural features.

Suction box for paper, etc., machines. ERNST KRAMER. Ger. 511,163, Sept. 14, 1929.

Hollander. GERALD STRECKER and ULRICH KIRCHNER. Ger. 514,215, Nov. 15, 1928.

Producing colored designs on paper, fabric, etc. HEINRICH BONGARTZ. Ger. 511,202, Nov. 9, 1928. In the method in which colors are sprayed on to the material

from the interior of a no. of rotating cylindrical stencils, a rapidly drying cellulose soln. is used as the medium for conveying the colors.

Colored and tinted parchment paper. ROBERT I. COWEN. U. S. 1,790,367, Jan. 27. The formed paper is passed through an acid bath such as a H_2SO_4 parchmentizing bath in which "Erie fast scarlet" or other suitable dye is suspended, and the paper thus treated is subsequently passed through a water bath to dissolve and diffuse the dye deposited in the amyloid film formed upon the fiber of the paper while passing through the acid bath and to wash out any excess of acid still present. Cf. *C. A.* **25**, 206.

Waterproof paper covering for food or tobacco packages, etc. WM. L. TAYLOR. U. S. 1,789,887, Jan. 20. A covering comprises a layer of paper coated with adhesive material consisting of asphalt and having superposed on the adhesive asphalt a layer of paper surface-coated with cold unmelted paraffin.

Paper. JACQUES F. M. CROLARD (to British-American Tobacco Co., Ltd.). U. S. 1,790,574, Jan. 27. See Fr. 688,350 (*C. A.* **25**, 817).

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE AND C. G. STORM

Consumption of explosives in December, 1930. W. W. ADAMS AND L. S. GERRY. Bur. Mines, *Rept. of Investigations* **3087**, 10 pp. (1931); cf. *C. A.* **25**, 1086. A. H. E.

Some experiments on certain accessory components of smokeless powders. MICHELE GIUA AND GIOVANNI RACCIU. *Atti accad. sci. Torino* **65**, 205–12(1930).—The action of oxides of N on 3 com. petrolatums was studied to find any possible relation between such action and the action of petrolatum as a stabilizer of smokeless powders. Petrolatum samples showing higher Br_2 absorption (over 0.04 g. Br_2/g. petrolatum) fixed more N as oxides (N_2O_3, N_2O_4, N_2O_5 were studied). A. W. CONTIERI

The detonation of solid explosives. P. LAFFITTE AND M. PATRY. *Compt. rend.* 191, 1335–7(1930).—With the addn. of an arc lamp to the arrangement previously described (*C. A.* **20**, 1324) a photographic study was made of the luminous phenomena of detonation of Hg fulminate, dynamite, picric acid, tetryl, etc., in a glass tube. To avoid optical interference of the glass walls of the tube, the tube was placed between 2 steel plates with horizontal openings 1 mm. high. These openings were in the same horizontal plane as the tube axis. On explosion the glass becomes partially or completely opaque, a non-luminous compression wave or shock wave is propagated in the air at the same time that the luminous gases are thrown forward. These 2 phenomena are distinct, that of the gas ending much more rapidly than the shock wave.
M. McMAHON

Manufacture of trinitrotoluene. A. A. TOPP. *Proc. Soc. Chem. Ind. Victoria* **30**, 385–411(1930).—The process and equipment at Maribyrnong are described.
E. M. SYMMES

New method for the preparation of tetryl. LOUIS DESVERGNES. *Chimie & industrie* **24**, 1304–16(1930); cf. *C. A.* **25**, 207. A. PAPINEAU-COUTURE

Propagation of combustion in hydrocarbon mixtures. M. AUBERT AND R. DUCHÊNE. *Ann. combustibles liquides* **5**, 737–9(1930).—See *C. A.* **24**, 5160. E. SCHOTTE

Technical safety questions in C_2H_2 welding (SAUERBREI) **9**. Making dangerous gases in sewers harmless (KARSTEN) **14**.

STELLINGWERF, G.: **Le Mine. L'impiego pratico degli esplosivi e il modo di calcolare e far brillare ad uso dei tecnici, civili e militari, costruttori, esercenti di cave e miniere.** Milan: Ulrico Hoepli. L. 16.

Explosives. DYNAMIT-A.-G. VORM. ALFRED NOBEL & Co. Ger. 513,397, Dec. 22, 1926. Gelatinous explosives and gelatinized smokeless powders are prepd. by gelatinizing with nitrocellulose the explosive oils obtained by nitrating a soln. of sorbitol in glycerol, glycol or like alc. The usual addns. may be included. Thus, a dynamite may comprise explosive oil (as above) 62, nitrocellulose 3, wood meal 8 and $NaNO_3$ 27%. Cf. *C. A.* **24**, 6020.

Treatment of nitrocellulose smokeless powder. EDGAR H. NOLLAU and JULIUS M. R. LINHART (to Canadian Industries, Ltd.). Can. 308,109, Jan. 27, 1931. Nitrocellulose smokeless powder is treated with a liquid soln. rich in aliphatic nitrocellulose solvent as a softening agent and contg. a nitrocellulose non-solvent as a gelatinization-

preventing agent, *e. g.*, ethyl acetate, alc. and water. The treated powder can be quickly dissolved in suitable solvents and may be used for making solns. and jellies used in the manuf. of artificial leather.

Tribromoaniline and its derivatives. HENRY DREYFUS. Fr. 692,370, Mar. 20, 1930. 2,4,6-Tribromoaniline is purified by sublimation at 160–65°, and the purified product may be acylated with Ac_2O or AcCl. The acyl derivs. are used for diminishing the inflammability of compns. having a basis of a cellulose deriv.

Nitroglycerin. ROBERT EVERS. Ger. 513,396, Aug. 19, 1927. Nitrating acid falls freely onto glycerol flowing in a thin sheet under pressure over a spherical surface, with the result that droplets of glycerol are entrained by the acid, the mixt. passing through a cooling coil fitted with mixing devices. App. is shown.

Pyrotechnic "salute." CHARLES SCARDONE. U. S. 1,789,372, Jan. 20. The casing of a salute is formed, of approx. spherical shape, from a solid block of material such as wood excavated to form an explosive chamber, and provided with a permanently secured closure.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

General process for the application of synthetic indigo in China. N. S. WONG LING. *Dyestuffs* **31**, 177–85(1930). CHAS. E. MULLIN

Nitroso colors. M. F. POZDIEV. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 4–5, 86–8(1930); *Chimie & industrie* **24**, 1410(1930).—From the results of a study of the optimum conditions for the production of Fe lakes, P. concludes that it is best to start from $FeSO_4$ rather than other Fe^{++} salts and to use 1 mol. for 5 mol. nitroso-β-naphthol, which would indicate that the Fe combines in the lake in the Fe^{+++} state. Steaming is best carried out for 3–5 min at 103–5° in the case of fabrics dyed with vat dyes, *i. e.*, in a reducing atm. As it was found that when the nitroso color was printed on naphtholated goods a better yield was obtained than on a white ground, P. deduced that this improvement was due mainly to the fat in the naphthol bath, or in other words, to the formation of a triple Fe-nitroso-fat lake. He finally adopted the following formula: nitroso paste (=10.7% β-naphthol) 300, 38° Bé. $NaHSO_3$ 65, solvent salt B 15, neutral thickener 500, 28% $FeSO_4$ 70, vaseline oil 40 g. A. PAPINEAU-COUTURE

Process for the rapid fixation of chrome colors. V. BORISOV AND N. SOKOLOV. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 3, 101(1930); *Chimie & industrie* **24**, 948.—After numerous lab. and com. expts., the following mordant was developed for the fixation of chrome colors by a short steaming treatment: dissolve 250 g. $Na_2Cr_2O_7$ in 550 cc. hot water and gradually add 200 g. glycerol; the originally yellow soln. gradually darkens and finally becomes dark green, at which point the mordant is ready for use. Two examples of formulas are given: (1) alizarin blue S 100, dissolved in water 200, T thickener 600, mordant 30, water to 1000; (2) seed ext. 100, boiling water 200, brilliant green 10, MeOH 50, T thickener 600, mordant 20, water to 1000. The formula of the T thickener is: corn starch 1200, 18° Bé. HCl 5, oleic acid 25, castor oil 10, water to 10,000. The goods are steamed 4 min. at 100–2° with low-pressure steam and washed with hot water. The fastness of the shades is as good as that obtained in the usual way. A. PAPINEAU-COUTURE

Preparation of quick-drying wood stains. R. J. TODD. *Dyestuffs* **31**, 152(1930).—From 4 to 6 oz. of suggested dyestuffs are heated on the water bath with 15 to 25 oz. of either ethylene glycol or diethylene glycol until soln. is complete, and this is diluted to 1 gal. with synthetic MeOH. These stains do not raise the grain of the wood. CHAS. E. MULLIN

Aniline black in the printing of naphtholated goods. B. A. RAZUNOV AND M. F. CHMEKEV. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 1–2, 145–6(1930); *Chimie & industrie* **24**, 944.—Aniline black for printing on naphtholated goods has the following compn.: paramine 3, aniline 60, 18° Bé. HCl 95, thickener (starch, gum tragacanth) 520, $NaClO_3$ 40, H_2O 42, $K_4Fe(CN)_6$ 240. In com. work this formula gave slight brownish shades, particularly with very finely engraved designs; this defect, which could not be observed in the lab. tests, was overcome by increasing the amt. of 18° Bé. HCl to 115 g., so that sufficient acid is supplied to all points of the printed fabric completely to neutralize the naphtholate. This black can be roll-printed on naphtholated goods on reserves prepd. with basic dyes and thickened diazo salts; it does not soil the roll and does not corrode the scrapers. The strength of the fabric is the same as when printed with aniline in the usual way. A. PAPINEAU-COUTURE

Control of the operation of quick-steaming apparatus for aniline black. P. P. SAZANOV AND N. N. PETROVA. *Izvestiya Tekstilnoi Prom. i Torgovli* 9, No. 1–2, 127–35(1930); *Chimie & industrie* 24, 942.—A careful analysis of the operation of the app. shows the necessity of providing a suitable humidifying system in advance of the steaming app. proper to counteract the heating of the goods during the reaction. The chief factors to be taken into consideration are: the formation of aniline black is an exothermic reaction, max. evolution of heat occurs around 75–80°, oxidation of aniline black takes place rapidly, and all the more so that the acidity of the bath is higher. The steaming app. should be constructed so that the prepd. goods can be introduced in a short time, sufficient to start the reaction, and so that they can be taken out at the time of max. evolution of heat to cool them somewhat; a humidifying chamber should also be provided to regulate the temp. and moisture content of the goods. It is also advisable to make periodical analyses of the atm. of the app. and of the condensation products formed. A. PAPINEAU-COUTURE

Bismark brown in aniline-black dyeing. I. FEIGUIN. *Izvestiya Tekstilnoi Prom. i Torgovli* 9, No. 1–2, 155(1930); *Chimie & industrie* 24, 943.—Use of Bismark brown catalyzes the production of aniline black, enabling the production of better and deeper shades, entirely out of proportion with the small quantity of Bismarck brown used and with an increase of 8–18% in the tensile strength of the fabric. A. P.-C.

Sulfur black. HARRY FISCHER. *Dyestuffs* 31, 149–51(1930).—The properties and application of sulfur blacks are considered and formulas suggested for the standing bath. CHAS. E. MULLIN

Influence of the halogens on the color of azo dyes. The spectral absorption of certain mono-azo dyestuffs. DUNCAN GRAHAM FOSTER. *J. Am. Chem. Soc.* 53, 654–60(1931).—A series of dyes, made by coupling diazotized *o*-, *m*- and *p*-Cl, Br and I derivs. of $PhNH_2$ with R salt were prepd. and their spectral absorptions in H_2O were compared with those of the halogen-free dye. The results show no simple relationship between the dyes attributable to variations in mol. wt. but a complicated effect distributed in different portions of the spectrum. The effect of position isomerism is for the most part the same as that observed by other workers. The chief absorption bands appear to be composed of 2 or more constituent bands. These have in 1 instance been calcd. The results are given as curves. C. J. WEST

Latest developments in the dyeing of insoluble azo colors. R. W. MARSSON. *Proc. Am. Assoc. Textile Chem. Colorists* 1931, 33–9; *Am. Dyestuff Reptr.* 20, 43–9(1931).—The following topics are discussed: the substantivity of the naphthols of the AS range; substantive naphthols in padding; proper rewetting in the coupling bath of material that has been dried after impregnation; dead cotton in naphthol dyeing; exhaustion of naphthol by use of common salt; the influence of formaldehyde in naphthol solns. and on naphtholated material; alkali-binding agents and their influence on the stability of diazo solns. in dyeing. MILTON HARRIS

The development of rayon dyestuffs. II. Viscose rayon dyes. R. BRIGHTMAN. *Ind. Chemist* 7, 3–4(1931); cf. *C. A.* 25, 595. E. H.

The action of diazonium salts on silk. P. SISLEY, A. SIMONNET AND J. P. SISLEY. *Bull. soc. chim.* [4], 47, 1389–94(1930); cf. *C. A.* 22, 1857, 4515.—The diazotized solns. of bases of the following types, when neutralized or used in the presence of AcONa in a cold bath for 30 min., give yellow, orange-yellow, or brown-yellow colors on silk: mono- and dichloroaniline, nitroaniline, nitrochloroaniline, chloro- and nitroanisidine, chloro- and nitrotoluidine, thioaniline, acetyl-*p*-phenylenediamine and dianisidine. Some of these amines give colors of industrial importance on account of their stability to scouring and bleaching. The following aminoazo compds. when diazotized couple with silk to yield interesting colors: aminoazobenzene and diethoxy, dimethoxy and ethoxymethoxy derivs., aminoazotoluene and aminobenzeneazo-*p*-aminotoluene. The silk, in addn. to the dye formed by coupling with the fiber, holds a certain amt. of the noncoupled diazo compd. which, on boiling with soap, forms a hydroxy deriv. which in turn couples with the unchanged diazo compd. to give a complex absorbed on the silk. Thus, when silk dyed with diazotized primuline is soap-boiled, a fast yellow is obtained, since the diazo compd of primuline is stable and it is the azofibroinazoprimuline dye which predominates. To study the coupling of *p*-nitrodiazobenzene (I) with fibroin, silk was treated with a cold soln. of I (neutralized by $CaCO_3$ or treated with AcONa) for 2 hrs., after which time there was no deepening of shade. Titration showed the coupling of an amt. of I corresponding to a silk content of 5.4% tyrosine. Tyrosine gives a yellow dye with I. Silk dyed with I, soap-boiled and rinsed, when reduced with $Na_2S_2O_4$ gave *p*-$H_2NC_6H_4NH_2$. Dyed with diazotized *o*-$O_2NC_6H_4NH_2$ and similarly treated, silk yielded *o*-$H_2NC_6H_4NH_2$ (cf. *C. A.* 23, 1134). The presence of the NO_2 group in silk dyed with diazo-

tized *o*-, *p*- or *m*-$O_2NC_6H_4NH_2$, or *p*-nitro-*o*-anisidine was shown by reduction with Na_2S. The resulting NH_2 group permitted the fiber to be diazotized and coupled with α-$C_{10}H_7NH_2$ and with β-$C_{10}H_7ONa$, giving violet-black and vivid red colors, resp. The azo dyes formed by coupling a diazo compd. with the tyrosine group of fibroin are comparable, in shade and reactions, with dyes such as *p*-nitrobenzeneazo-*p*-cresol, the difference in fastness to scouring being attributable to the large protein mol. C. R. ADDINALL

Dyeing processes for artificial silks and for several important artificial silk combinations. W. E. v. GRONOW. *Kunststoffe* **20**, 275–7(1930).—A review of the classes of dyes suitable for use with various kinds of artificial silks and their combinations with other fibers, including detailed directions for a no. of special cases. I. H. ODELL

Dyeing of wool and silk mixed fabrics. E. H. STAAB. *Dyestuffs* **31**, 145–8, 158–60 (1930).—Dyestuffs, formulas and methods are suggested. CHAS. E. MULLIN

The fastness of khaki-colored sulfur dyeing as a function of the preliminary treatment of the fabrics. A. Y. ITKIN. *Niti* (*Suppl. to Izvestiya Tekstilnoi Prom. i Torgovli*) **1**, No 3, 12–5(1930); *Chimie & industrie* **24**, 924. Comparative tests carried out on samples taken at various stages of the mfg. process and also on lab.-prepd. samples showed that, while the preliminary operations (removal of the sizing and fats) facilitate the penetration of the dye, they have no effect on the fastness. A. P.-C.

Effect of the valence of electrolytes in substantive dyeing. P. P. VIKTOROV AND A. A. LEBEDEV. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No 1–2, 121–7(1930); *Chimie & industrie* **24**, 943.—The action of electrolytes toward substantive dyes increases according to the valence of their cations, increasing from univalent to tervalent cations, which confirms the law of valences according to which the coagulating power of an electrolyte increases with the valence. Expts. show that, in spite of the higher degree of dissocn. of univalent electrolytes, their coagulating action is lower than that of tervalent electrolytes, indicating that valence as well as degree of dissocn. affects the coagulation of the dye. In printing with direct dyes, the fiber takes up 10 times as much color in the presence of univalent electrolytes as in the absence of electrolytes, and 30% more in the presence of tervalent than in presence of univalent electrolytes. A. P.-C.

"Shibori" and "Kasuri" (dyeing in Japan). N. TAKATA. *Dyestuffs* **31**, 153–5 (1930).—Shibori is indigo-dyed by the tied-and dyed system to give white resists. Kasuri is cloth woven from indigo-dyed yarn in which both warp and weft has been tied and dyed to give resisted patterns in the woven goods. General instructions are given. CHAS. E. MULLIN

Screen printing on textiles. LLOYD H. WINNELL. *Dyestuffs* **31**, 165–73(1930). Method and formulas are given CHAS. E. MULLIN

Marking-off and bleeding of vat-dyed colored-effect cotton goods in kier boiling. CHAS. E. MULLIN. *Melliand* **2**, 88–9(1930). The marking-off and bleeding of vat dyed colored-effects in cotton piece goods in kier boiling may be caused by the presence of O in the kier, which forms oxidized cellulose very readily in the alk. kier liquor at high temps. It has been proved that oxidized cellulose has reducing properties and that it will reduce vat dyes, such as flavanthrene, etc. CHAS. E. MULLIN

Padding—its limitations and possibilities. E. W. PIERCE. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 45–8; *Am. Dyestuff Reptr* **20**, 55–8(1931).—Padding in general is recommended on account of its great uniformity and production; the results compare favorably with any other method of coloring. Goods which cannot be penetrated by either piece dye or jig dyeing may be colored through on a padder. Delicate fabrics, such as voiles, chiffons, and various goods made of rayon are not subjected to the wear and tear of the other processes and its possibilities are not yet exhausted. MILTON HARRIS

Washing-fastness tests. HUGH CHRISTISON. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 55–7; *Am. Dyestuff Reptr.* **20**, 77–9(1931).—Test 1: Treat with 5 g. 88% dry soap per l., 2 g. dry Na_2CO_3 per l. 8 hrs. in the Launderometer at 120° F. Test 2: Use the same soln. 2 hrs. Test 3: Treat with 5 g. 88% dry soap per l. 2 hrs. Test 4: Use 5 g. 88% dry soap per l. for 0.5 hr. MILTON HARRIS

Fastness of dyes to perspiration. C. C. N. VASS. *J. Soc. Dyers & Colourists* **47**, 9–10(1931); cf. *C. A.* **24**, 4637. ROBERT HOUGHTON

Abnormal fading. WM. H. CADY. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 39–42; *Am. Dyestuff Reptr.* **20**, 49–52(1931).—The action of light on various dyestuffs is discussed. MILTON HARRIS

Textile conditions, processes and products in Europe. CHAS. E. MULLIN. *Textile Colorist* **53**, 13–6; *Am. Dyestuff Reptr.* **20**, 17–9; *Melliand* **2**, 1329–31(1931).—European textile conditions and the dyeing and finishing processes and equipment are compared with the American processes, conditions, and app. CHAS. E MULLIN

Mineral oil sulfonates applied to textiles. B L. HATHORNE. *Proc. Am. Assoc. Textile Chem. Colorists* **1931**, 25–30; *Am. Dyestuff Reptr.* **20**, 35–40(1931).—Mineral oil sulfonates are extremely stable, even under conditions that completely destroy sulfonated animal and vegetable products. They are sol. in water and in mineral oils, vegetable oils, fats, waxes and org. solvents. Emulsifying properties exceed those of soap and sulfonated castor oil. They will stand up in the presence of weak acids or alkalies, are very resistant to hard water, since they do not form insol. lime and Mg salts as rapidly as do soap and sulfonated castor oil. MILTON HARRIS

Hard industrial water in the textile industry. M. MÜNCH. *Z. ges. Textil-Ind.* **33**, 664–6, 678–9(1930).—An illustrated description is given of the harmful action of lime soaps on textiles, and their possible emulsification by the use of such sol. oils as "Intrasol" in dyeing and rinsing operations. H. F. LEUPOLD

Starch products in textile finishing. IRA L. GRIFFIN. *Proc. Am. Assoc. Textile Chem Colorists* **1931**, 49–52; *Am. Dyestuff Reptr.* **20**, 71–4(1931).—A discussion of various starches including their origin, properties and application to textiles. M. H.

Trisodium phosphate, its manufacture and [illegible]

[illegible] of Na_3PO_4 from H_3PO_4, Na_2CO_3 and NaOH takes place in two steps: (*a*) the formation of Na_2HPO_4 and (*b*) the causticizing of Na_2HPO_4 with NaOH. It is used in boiling-off cotton goods or raw stock, wool scouring on raw stock piece goods, rayon scouring and in dye baths where the water contains Ca and Mg hardness. MILTON HARRIS

Detection of active chlorine or active oxygen in textiles. K. SCHWARZE. *Z. angew. Chem.* **44**, 44(1931). —Moisten the fabric with dil. mineral acid, place KI-starch paper on both sides and two clean glass plates on the other side of each piece of paper and place in a press. If Cl_2 is present the paper will turn blue A similar procedure will serve to detect traces of acid or base in cloth; water to wet the goods and suitable indicator papers are used. W. T. H.

Study of the structure of vegetable fibers by solution in concentrated sulfuric acid. A. I. ZAKOCHTCHIKOV. *Izvestiya Tekstilnoi Prom i Torgovli* **9**, No. 1–2, 137–40(1930); *Chimie & industrie* **24**, 944. —If a drop of 65.5° -Bé. H_2SO_4 is added to a vegetable fiber on a microscope slide, the fiber dissolves before the phenomenon can be followed under the microscope but if a drop of glycerol is added after the H_2SO_4 the soln. phenomenon is stopped and can be studied under the microscope at any desired stage. Z. first observed this with flax, and noted that the solvent action of H_2SO_4 is not uniform: certain portions are destroyed first, revealing clearly defined membranes similar to 2 adhering sheets. The regular arrangement of these membranes indicates that they form part of a definite structure of the fiber, with a different chem. compn. as they are more resistant to the action of H_2SO_4. Hemp, "kendyr," "kenaf" and ramie also have these membranes. Washing with Cl water, or even better with a soln. contg. 10 parts $ZnCl_2$ and 1 part KI, after addn. of glycerol brings out the morphological characteristics more clearly, the portions attacked by H_2SO_4 becoming bluish black. With cotton, the membranes show up only after addn. of the $ZnCl_2$ KI soln and of lactic acid. A. PAPINEAU-COUTURE

Chemical composition and mechanical properties of "kenaf" fiber as a function of watering of the plants. V. T. IVANOVA. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 1–2, 140–4(1930); *Chimie & industrie* **24**, 944.—In southern U. S. S. R., where the cultivation of "kenaf" has been undertaken on a large scale, drought is frequent. Systematic artificial watering results in a higher yield of stronger fiber, increases the cellulose, lignin, fat and resin contents of the fiber, and reduces its moisture and ash contents. A. PAPINEAU-COUTURE

Effect of moisture on the strength and elongation of yarn. P. D. ERMOLENKO *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 3, 39–44(1930); *Chimie & industrie* **24**, 945. —Yarn tested at a relative humidity of 60–80% was 11–51% stronger and had 8–42% greater elongation than dry yarn tested in an absolutely dry atm. A. P.-C.

Micelle structure of the wool fiber. J. B. SPEAKMAN. *Nature* **126**, 565(1930).—Existence of micelles within the wool fiber were proved by swelling and adsorption studies and by the action of Na_2S on wool. It was deduced that the micelles are lamellar in shape H. H. MOSHER

Effects of water treatments and steam treatments on the hygroscopic properties of wool fibers. N. A. ARKHANGELSKII. *Niti* (*Suppl. to Izvestiya Tekstilnoi Prom. i Torgovli*) **1**, No. 3, 11–8(1930); *Chimie & industrie* **24**, 947.—Wool treated with water and with steam and untreated wool were conditioned 2 weeks in an atm. at 60% relative humidity and then dried to const. wt. at 102–9°. While the results obtained so far are

insufficient to draw definite conclusions, they indicate that, after conditioning, the water-treated wool contained a little more moisture and the steam-treated wool a little less moisture than the untreated wool. A. PAPINEAU-COUTURE

The oiling of wool fibers with aqueous emulsions of fats. LOUIS MEUNIER AND JACQUES CORBIÈRE. *Compt. rend.* **191**, 661–3(1930).—Adsorption by wool fibers from emulsions of olive oil stabilized by NH_4 oleate was studied. Oil particles less than 1μ in diam. were not adsorbed. Particles of 2μ were adsorbed in the greatest no., but the largest mass of the adsorbed oil was accounted for by a comparatively small no. of 8–11μ droplets. When the soap content of the emulsion amounts to 15% of the oil, the amt. of adsorbed oil decreases because of the increased stability of the emulsion. The compn of the adsorbed material is identical with the material in the emulsion when the oleic acid concn. is below 6.5%. Above this proportion, oleic acid is preferentially adsorbed. Wool shows a rapid increase in oil adsorptions between p_H 4.5 and 3 and a slower increase between 3 and 1. Swelling of the wool was at a min. at p_H 4.5. Above this p_H the proportion of oleic acid in the adsorbed layer also increased. J. G. MCNALLY

Action of sodium sulfide on wool. J. B. SPEAKMAN. *J. Soc. Chem. Ind.* **50**, 1–7T (1931).—Microscopically, it was shown that wool cuticle is far more resistant to Na_2S than the cortex, and that the reagent produces dimensional changes. Chemically, it was proved that the reaction between wool and Na_2S is partially reversible and undergoes rapid acceleration by increases in the concn. of the soln. and time Neither the elastic phase nor the hygroscopic properties of wool partially destroyed by Na_2S were influenced by the reaction, though the permanent set produced by steaming was eliminated. The nature of this set suggests that the disulfide group in wool is masked by an anhydride group, and the action of wool treated with Na_2S toward water, forces the conclusion that the micelles of the wool fiber are lamellae, which are attacked and eaten away at the edges, leaving the ratio of surface to mass unaltered. It is also suggested that the disulfide linkage in wool is the point of attack by Na_2S, and lies in a plane that makes an angle with the main face of the micelles. H. H. MOSHER

The utilization of reindeer wool. V. N. PETELINA. *Niti* (*Suppl. to Izvestiya Tekstilnoi Prom. i Torgovli*) **1**, No. 3, 18–9(1930); *Chimie & industrie* **24**, 946.—To obtain a general idea of the compn. of a sample obtained from a female reindeer from the Island of Jamala, Ouralsk province, 4 g. was gathered into a bundle, washed with Et_2O and sepd. mechanically into down (55.81%, 13.5–44 mm. long), live hair (1.26%, 22–40 mm long), shives ("arête") (0.33%, 8–22 mm. long), and dead hair (42.6%, 23–40 mm. long) The thickness of the down (the only portion which might be of com interest) detd. on 100 samples was 0.013 mm., with a variability, calcd. from Sommer's formula, of 14.51%
A. PAPINEAU-COUTURE

Cooking flax yarn with sodium oxalate. G. A. KORZHENIOVSKII. *Niti* (*Suppl to Izvestiya Tekstilnoi Prom. i Torgovli*) **1**, No. 3, 15(1930); *Chimie & industrie* **24**, 946.—Comparison of the boiling of flax with H_2O, Na_2CO_3 and $Na_2C_2O_4$ showed that $Na_2C_2O_4$ does not effect as complete purification of the fibers as Na_2CO_3, that the oxidizable substances are eliminated as easily by Na_2CO_3 as by $Na_2C_2O_4$, that the loss in wt. is much greater with Na_2CO_3, and that bleaching is much more rapid after boiling with $Na_2C_2O_4$. A. PAPINEAU-COUTURE

Experiments on the application of neutral salts to the cottonization of flax. A. P. ZAKOCHTCHIKOV, I. A. KOHYENIOV AND E. YKIOUCHKIN. *Izvestiya Tekstilnoi Prom i Torgovli* **9**, No. 3, 91–5(1930); *Chimie & industrie* **24**, 949.—The action of $(NH_4)_2C_2O_4$ as pectin solvent has long been known, and expts. on flax gave very good results. $Na_2C_2O_4$ behaves similarly, but not free $H_2C_2O_4$ The specific action of neutral alkali salts of $H_2C_2O_4$, which is not shown by other alkali metal salts, *e. g.*, NaCl, is explained as follows: whereas the Ca-Mg salt of anhydroarabinogalactosemethoxytetragalacturonic acid, which constitutes pectin, is insol., its Na salt is sol. in H_2O, and in this form it can be easily removed from flax. This salt is produced by double decompn., and at the same time CaC_2O_4 ppts. out, as shown by the turbidity of the bath. The accuracy of this hypothesis is also shown by the fact that the neutral alkali salts of acids giving difficultly sol. Ca or Mg salts can also be used for cottonizing flax: *e. g.*, NH_4F, $Na_2B_4O_7$, Na_2CO_3, but the best yields are obtained with Na or NH_4 oxalates. A. P.-C.

The problem of the cottonization (of flax). A. A. AKSIPETROV AND G. N. RIOUMIN. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 3, 89–91(1930); *Chimie & industrie* **24**, 948 **The following process is recommended: the previously moistened flax is steamed 2 hrs at 120–50°, washed thoroughly, and centrifuged. This removes most of the pectin compds., and the fiber is easily carded. The phenomenon consists of an acid hydrolysis as the liquid draining from the centrifuge is acid, and also the distillate collected during the steaming.** A. PAPINEAU-COUTURE

Effect of certain methods of cottonizing on the quality of the product obtained. B. M. LOTAREV. *Niti (Suppl. to Izvestiya Tekstilnoi Prom. i Torgovli)* **1**, No. 1–2, 17–8(1930); *Chimie & industrie* **24**, 942–3.—There are 3 processes for cottonizing flax fibers: cooking with NaOH, oxidizing with hypochlorite, mercerizing. Comparison of the 3 processes showed that the greatest sepn. of the fibers is obtained by mercerizing, followed in order by alk. cooking and oxidation with hypochlorite. None of the processes appreciably weakens the fibers. A. PAPINEAU-COUTURE

Observations on Aspergillus on cotton. V. A. KUTIEICHTCHIKOV. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 3, 57–60(1930); *Chimie & industrie* **24**, 945–6.—Mech. operations such as spinning and weaving do not eliminate *Aspergillus* from cotton, nor does sizing because the heating to which the cotton is subjected during sizing is insufficient. The acid and alk. treatments generally used are not sufficiently drastic completely to eliminate the fungus, the only one of the usual chem. treatments which is really efficient for the purpose being the boiling under pressure with NaOH.
A. PAPINEAU-COUTURE

The rayons and acetate silk. CHAS. E. MULLIN. *Textile Colorist* **52**, 17–20, 93–5 (1930).—A review of some of the developments in this industry, as well as in dyeing, finishing, and handling the synthetic yarns. CHAS. E. MULLIN

The process of silk soaking. FOSTER D. SNELL AND CYRIL S. KIMBALL. *Proc. Am Assoc. Textile Chem. Colorists* **1931**, 57–9; *Am. Dyestuff Reptr.* **20**, 79–81(1931).—The alkali content of the soaking bath should be kept low, depending mainly on absorption of the oil and water for softening effect. If the soap content is low, the formation of the alkali sericin compd. will be at a minimum. MILTON HARRIS

Uniformity of singeing. Heat treatment and its effect on the processing of textile fabrics. JOHN T. TRAVIS. *Am. Dyestuff Reptr.* **20**, 33–4, 61–3(1931).—The normal moisture content of the yarn or cloth should be eliminated before singeing, as disintegration and combustion, to at least some extent, may result with loss of tensile strength in the individual fibers. Oxycellulose developed without any change in the C content of the fiber will result in a higher luster and a greater affinity for dyestuffs. Uniformity and effectiveness of heat treatment in preparatory work are without doubt essential features in fabric processing. MILTON HARRIS

Seraceta. C. P. ATKINSON. *J. Soc. Dyers Colourists* **47**, 5–7(1931).—Seraceta acetate warp yarns are usually heavily sized with gelatin; its removal is essential. The ideal method is: Soak in cold water a short time, jig treat in water, raising the temp. to 80°. Pad with "Courtauld's Desizing Compound" ($4^1/_2$ lb. Monopole Soap No. 1, 4 pints NaOH 40° Tw., $2^3/_4$ pints xylene). Let stand overnight, scour regularly and prop. The tables show the effect of p_H on delustering and of soaps and of soap-phenol mixed solns. on degumming and delustering and on phys. and dyeing properties of Seraceta and of silk. Various crepeing conditions are mentioned. The properties of Opaceta are described. A. K. JOHNSON

New bleaching process. A. P. ORANSKII. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 1–2, 136–7(1930); *Chimie & industrie* **24**, 943–4.—The process is carried out as follows: the fabric is impregnated on the jigger with a 0.5°-Bé. NaOH soln., placed in a Thies boiler where it is heated 1 hr. at 85° with circulation of the liquor, washed in the boiler first with hot and then with cold water; after a light souring, the goods are treated for 40 min. at 35° with hypochlorite soln. contg. 1 g. available Cl per l., washed, acidified with 0.3% H_2SO_4 at 20° for 20 min., washed twice and dried. By working carefully the goods are of as good quality as those bleached in the usual manner, except that they contain more oxycellulose because of the higher concn. of hypochlorite used. The process has been adopted by the largest dyeing and printing works in the U. S. S. R. (formerly Emile Zundel). A. PAPINEAU-COUTURE

Continuous bleaching process. N. V. FILIPPOV AND B. S. VORONKOV. *Izvestiya Tekstilnoi Prom. i Torgovli* **9**, No. 1–2, 135(1930); *Chimie & industrie* **24**, 943.—In the proposed bleaching process the usual souring and boiling operations (which require 6–12 hrs.) are replaced by a relatively short (30–40 min.) treatment in open tanks with 3–4°-Bé. NaOH contg. a wetting agent (soap, Na sulforicinate or ricinate, etc.) and alkali metal salts (Na silicate, Na and K sulfites, etc.); the goods are washed first with hot and then with cold water, and the bleaching is continued as usual by passing for 30 min. in a 0.2–0.5°-Bé. Ca hypochlorite soln., washing, acidifying, washing and drying. The strength and other properties of fabrics treated in this way are practically the same as when bleached in the usual way. A. PAPINEAU-COUTURE

"Bleach killing" of furs. JOSEPH CASPE. *J. Tech. Assoc. Fur Ind.* **1**, 161–7 (1930); *cf. C. A.* **24**, 3906.—Expts. were carried out to det. the effects of varying concns. of NH_4OH and H_2O_2 on the rate of protein hydrolysis in the raw skins and hair of Aus-

tralian rabbit, by the same method as in the previous work. The amt. of H_2O_2 consumed was also detd. On skin and hair together, treated for 2 hrs. at 25°, increasing the concn. of H_2O_2 to 1.5% caused the protein hydrolyzed to increase gradually to 5%; further increase in H_2O_2 to 3% gave no further effect. With the same treatment of hair alone, a plateau was reached at 1.875% H_2O_2, with hydrolysis values 60% higher than in the case of hair with skin; this indicates that the main action is on the hair. Increasing the time of treatment to 6 hrs. gave only slight increases in percent of hydrolysis. Raising the temp. to 35° increased the speed of hydrolysis but had no other effect; high temp. should, therefore, be avoided to prevent too rapid decompn. In the absence of NH_4OH practically no hydrolysis occurred. The protein hydrolysis has no direct bearing on the amt. of H_2O_2 consumed, but is related to the concn. of H_2O_2. I. H. ODELL

Dyeing textiles. DEUTSCHE HYDRIERWERKE A.-G. Ger. 512,638, Feb. 5, 1927. The wetting-out and permeating properties of alkali baths for textiles (*e. g.*, dyeing, washing, mercerizing, etc., baths) are improved by adding sulfaminocarboxylic acids (*e. g.*, obtained by condensing org. sulfo acids and aminocarboxylic acids) or their homologs, substitution products or water-sol. salts. Examples mention tetrahydronaphthalenesulfaminoacetic acid.

Dyeing textile materials. I. G. FARBENIND. A.-G. Brit. 335,048, Sept. 7, 1929. Discharge effects are produced by impregnating textile materials with a coupling component such as 2,3-hydroxynaphthoic acid, a naphthol or a deriv. of 1-naphthol-4-carboxylic acid, printing the impregnated material with a paste contg. an ester-salt of a leuco-vat dye, an insol. chromate such as Ba or Pb chromate and an alkali metal sulfite, and developing with a diazo compd. without previous steaming. Several examples are given.

Dyeing materials such as cotton and wool. D. A. W. FAIRWEATHER, J. THOMAS and SCOTTISH DYES, LTD. Brit. 334,921, March 7, 1929. Products, believed to be tetrasulfuric esters of tetrahydrodianthraquinoneazines, obtained by oxidizing 2-aminoanthrahydroquinone-9,10-disulfuric ester or a substitution product having the 1-position free in alk. soln., are used in dyeing fibers, with or without isolating the products from their solns. Various details are given for dyeing materials such as cotton and wool. The dye may be developed with HCl and $CuSO_4$.

Dyeing animal fibers. I. G. FARBENIND. A.-G. Fr. 691,996, Mar. 15, 1930. The absorptive capacity of animal fiber for acid and direct dyes in a neutral bath is reduced

or annulled by previously treating the fibers with di- or poly-aralkylaryl compds. contg. SO_3H or COOH groups, or by adding such compds. to the dye bath. Examples are given of the use of 3,5-di(6′-hydroxy-3′-chloro-5-sulfobenzyl)-4-hydroxy-1-chlorobenzene and of the condensation product of *o*-benzylphenol with benzyl chloride-4-sulfonic acid.

Dyeing silk. Soc. anon. pour l'ind. chim. à Bâle. Fr. 691,972, Mar. 15, 1930. Charged or uncharged silk is dyed by metallized derivs. of azo dyes obtained from *o*-aminophenols or diazotized *o*-aminocarboxylic acids and aminonaphtholsulfonic acids or their *N*-substituted derivs. A table of components and the shades obtained is given.

Dyeing artificial silk. Soc. pour la fabrication de la soie "Rhodiaseta." Fr. 692,432, June 17, 1929. Black artificial silk is obtained by suspending very finely divided C, particularly lampblack, in a collodion having a basis of cellulose esters and afterward spinning the collodion thus colored. The collodion may be filtered before spinning if desired.

Dyeing; printing. Durand & Huguenin S. A. Ger. 513,357, June 10, 1928, and 513,358, Sept. 16, 1928. See Brit. 313,407 (*C. A.* **24**, 1228) and 319,021 (*C. A.* **24**, 2614).

Printing. I. G. Farbenind. A.-G. (Paul Nawiasky, Alfred Ehrhardt and Gustav Bernardy, inventors). Ger. 514,166, July 1, 1928. Animal, vegetable or artificial fibers are printed with an alk. paste contg. an alkali-sol. condensation product obtained as described in Ger. 483,154 (*C. A.* **24**, 508). The blue-green color is developed by oxidation, *e. g.*, with $K_3Fe(CN)_6$ or $(NH_4)_2S_2O_8$. An example is given.

Printing textile materials. I. G. Farbenind. A.-G. Brit. 334,907, May 11, 1929. Textiles are printed with use of the stable reduction products of 4,4′-dimethyl-6,6′-dihalothioindigo or of 6,6′-diethoxythioindigo (which may be obtained as described in Brit. 334,878, Brit. 334,919 or Brit 334,920). If reducing agents are concurrently applied they are generally used in smaller quantities than when printing with unreduced dyes. Various details of procedure are described.

Printing fabrics. I. G. Farbenind. A.-G. Fr. 691,070, Mar. 4, 1930. Fabrics are printed with dyes with which polyvinyl alc. and if necessary other substances such as starch are incorporated as thickening agents, but no alkalies, and the fabrics are subsequently treated with a bath contg. an alkali and if necessary a reducer.

Printing cellulose ester or ether materials. British Celanese, Ltd., and J. A. Wainwright. Brit. 335,206, June 19, 1929. Fabrics, etc., formed with esters such as formate, acetate or propionate or butyrate of cellulose or methyl, ethyl or benzyl cellulose or the product produced by treating alkalized cellulose with *p*-toluenesulfonylchloride are printed with plates or rollers engraved to varying depths to produce graded color effects. Various details of procedure are described.

Apparatus for examining dyed cloth under artificial light. Imperial Chemical Industries, Ltd. Fr. 690,855, May 1, 1930.

Experimental dyeing apparatus. I. G. Farbenind. A.-G. (Theodor Kircheisen, inventor). Ger. 513,285, Sept. 15, 1929.

Dyeing, bleaching, etc., apparatus for treating sheet materials with circulating liquids or gases. Eduard R. Müller. Austrian 119,695, May 15, 1930.

Apparatus for dyeing or other treatment of textile materials in lengths. Wilhelm B. Bronander. U. S. 1,790,132, Jan. 27. Structural features.

Apparatus for dyeing yarn locally. Eclipse Textile Devices, Inc. Ger. 511,734, Jan. 9, 1929.

Oxidizing apparatus for aniline-black dyeing. Paul Baumert. Ger. 511,204, Sept. 16, 1926.

Apparatus (with superposed trays) for dyeing or other liquid treatments of packages of yarn or other textile materials. John C. Hebden (to Dyeing Processes Corp.). U. S. 1,789,745, Jan. 20. The trays are arranged in variable spaced relation for holding the packages of material between them and are provided with passages for supplying the treating liquid to the packages.

Apparatus for treating fibers with liquids such as dyes, etc. Compagnie nationale de matières colorantes & manufactures de produits chimiques du nord réunies. Ger. 512,715, May 24, 1928. Details of arrangement are given.

Treating fabrics. Société pour la fabrication de la soie "Rhodiaseta." Ger. 512,637, July 31, 1927. Fibers or fabrics of acetate silk are given a mat wool-like finish by treatment with $CaCl_2$, $MgCl_2$ or $LiCl_2$ soln. in the cold, and immersion, for a short time, in aq. mineral or org. acid of under 0.1*N* strength. Several examples and a table of acids, strengths and results produced are given.

Kier treatment of textile materials. Eugene D. Jefferson (to Rodney Hunt Machine Co.). U. S. 1,789,953, Jan. 20. An app. is described in which liquid flows

intermittently into the central portion of a mass of the goods in the kier and onto the goods from above, with provision of seepage intervals between sprays.

Degumming textile plants. URBAIN J. L. THUAU. Fr. 692,429, June 15, 1929. Textile and vegetable plants are degummed for their use in *textile industries, paper making*, etc., by means of sulfonic acids, particularly naphthalenesulfonic acids in the presence or not of NaCl or other mineral salts. The product is then neutralized.

Wet spinning of flax, hemp and other textile fibers. GRIGORI PETROV (one-half to Nicolai Aleskeev). U. S. 1,789,414, Jan. 20. Moistening is facilitated by adding to the water used for wetting a very small quantity of an aromatic sulfonic acid having a "mean mol. wt." not over 350, such as a naphthalenesulfonic acid.

Machine for the wet treatment of fabrics in open width. MASCHINENFABRIK BENNINGER A.-G. Ger. 513,198, July 21, 1929.

Apparatus for the wet treatment of yarn. PETER CALDWELL and THE BRITISH COTTON AND WOOL DYERS' ASSOCIATION, LTD. Ger. 511,735, Mar. 5, 1926.

Smoothing and dressing yarn, thread, cords, etc. FIRMA A. MONFORTS. Ger. 511,114, July 12, 1928. See Brit. 315,304 (*C. A.* **24**, 1750).

Impregnating textile fibers. JEAN E. C. BONGRAND and LÉON S. M. LEJEUNE. Ger. 512,796, Nov. 19, 1929. The wound fibers are enclosed in a vessel with natural or artificial rubber latex and N under pressure. The spools of fiber are then washed to remove excess of latex, immersed in a bath of rubber latex, rewound, dried and coagulated.

Impregnating textiles, wood and other materials. I. G. FARBENIND. A.-G. Brit. 335,247, June 20, 1929. To increase their resistance to wear and exposure to weather and to acids and alkalies, mixed cotton and wool fabrics, other textile materials, wood, paper, etc., are impregnated with solns. in org. solvents of water-insol. cellulose derivs. such as nitrocellulose or ethyl cellulose and bituminous substances such as coal pitch or petroleum pitch, in such diln. that the pores remain free (suitably with various modifying and auxiliary substances examples of the use of which are given). Cf. *C. A.* **24**, 2815.

Impregnating cloth. SIEGMUND KOCH. Fr. 691,607, Mar. 8, 1930. Jute sacks, tent canvas, etc., are impregnated with a soln. of balata in a solvent formed of equal parts of CS_2 and trichloroethylene and to which known fillers such as Zn white or asbestos powder are added.

Metallizing fibrous material such as lace and other fabrics. FRITZ NEUBER and RUDOLF NOWAK (to Oskar Trebitsch). U. S. 1,790,615, Jan. 27. A noble metal such as Ag is pptd. upon fibrous material by reduction from a salt of the metal, incompletely reduced substances are dissolved out with a solvent contg. a protective colloid such as glue or gelatin, and the material is compressed to produce a strongly adherent covering of pure metallic appearance on the fibrous material.

Artificial threads. HEBERLEIN & CO. A.-G. Fr. 691,026, Mar. 3, 1930. Artificial threads are made from solns. of cellulose in ammoniacal-CuO using as pptn. bath an alkali lye of the concns. usually employed for mercerization and cooled to below 0°. The threads may first be pptd. and then passed through the cooled lye.

Artificial threads, films, etc. HEBERLEIN & CO. A.-G. Fr. 692,371, Mar. 20, 1930. Threads, ribbons, films, etc., of regenerated cellulose are made by pptg. cellulosic solns. in concd. mineral acids contg. pyridine, its homologs or their derivs., as free bases or salts miscible with the bath.

Artificial threads, films, etc. HEBERLEIN & CIE A. G. Fr. 692,273, Mar. 19, 1930. Films, threads, etc., are made from regenerated cellulose by pptg. solns. of cellulose with concd. mineral acids contg. CH_2O, its condensation products or derivs.

Artificial threads. I. G. FARBENIND. A.-G. Fr. 692,027, Mar. 17, 1930. Curled and waved artificial threads or fibers are prepd. by treating threads, etc., obtained from the polymerization or transformation products of butadiene or its homologs, *e. g.*, those substituted in the 1 or 1 and 4 positions or their derivs., with liquid, emulsions or suspensions composed of org. agents, preferably those which cause a swelling of the thread. Hydrocarbons or their halogen derivs., ethers, esters, monohydric alcs., aldehydes, sulfonic acids or sulfuric esters may be used. Examples are given of the use of dipentene, dipentene and toluene, a mixt. of alc., glycol, $C_6H_5CH_2OH$ and toluene, and other mixts.

Artificial silk. W. MARSHALL. Brit. 335,176, June 17, 1929. Softness, extensibility, elasticity, tensile strength and even dyeing properties of regenerated cellulose threads and films and of textile materials coated or impregnated with regenerated cellulose are improved by treating the material with NaOH or KOH soln. of not less than 28° Tw. and the removing at least most of the alkali by washing with aq. solns. of

NaCl, KCl, Na_2SO_4, K_2SO_4, $NaNO_3$, KNO_3, $NaClO_3$, $KClO_3$, $Na_2S_2O_3$, NH_4Cl, $(NH_4)_2SO_4$, sucrose, glycerol or glucose. Various details of procedure are described.

Finishing fabrics comprising artificial cellulose derivatives. BRITISH CELANESE, LTD. Brit. 335,138, Jan. 12, 1929. Crepe, pebble and crinkled effects are produced on netted, woven or knitted fabrics formed of org. derivs. of cellulose such as cellulose acetate by the local application of a soln. of HNO_3 of 10–60° Tw. (which may be applied by engraved or embossed rollers or blocks or by brushing or spraying through stencils or by a light spray in spots or stripes, with or without a dye or thickening substance).

Dulling cellulose esters and ethers. I. G. FARBENIND. A.-G. (Richard Fischer and August Baumert, inventors). Ger. 512,399, April 8, 1928. See Fr. 672,217 (*C. A.* 24, 2291).

Treating fabrics of cellulose acetate, etc. BRITISH CELANESE, LTD., W. A. DICKIE and R. W. MONCRIEFF. Brit. 335,180, June 17, 1929. Fabrics are formed contg. both shrunk and unshrunk yarns of cellulose acetate or other org. cellulose derivs. so that on treating them with a shrinking agent (such as HNO_3 of 20–45° Tw.), crepe, semi-crepe, pebble or other ornamental effects may be produced while the fabric is capable of being dyed a level shade. The shrinking agent may be applied locally if desired to produce local effects or designs.

Treating knitted fabrics comprising cellulose acetate, etc. BRITISH CELANESE, LTD. Brit. 335,139, Jan. 12, 1929. A shrinking agent such as HNO_3 is applied to knitted fabrics formed, at least in part, of cellulose acetate or other org. deriv. of cellulose and reduces the tendency of the fabrics to develop faults such as laddering, running or splitting and also reduces the luster of the material to some extent. The fabrics may also contain silk, cotton or regenerated cellulose.

Fabrics comprising cellulose acetate or other organic cellulose derivatives. BRITISH CELANESE, LTD., W. I. TAYLOR and C. DREYFUS. Brit. 335,204, June 15, 1929. In order to reduce the luster of articles such as stockings, made of cellulose acetate or the like, abrasive material is rubbed over their surface. Pattern effects may be produced by localized application of the abrasive material Various details of procedure are described.

Crepe effects on acetylcellulose fabrics. SOC. POUR LA FABRICATION DE LA SOIE "RHODIASETA" Brit. 335,020, Aug. 14, 1929 Crepe effects are produced on fabrics formed at least in part of highly twisted cellulose acetate yarns by treatment of the material in a bath having a marked swelling action but little or no peptizing action on the cellulose acetate. Among the substances which may be used for this purpose are: EtOH or MeOH or their mixts. with water and saline solns., benzene, toluene, C_2HCl_3, CCl_4, guaiacol or aniline emulsions or aq. solns. of EtOAc. Fabrics formed in part from viscose and in part from cellulose acetate may be treated.

Warp beams (for artificial silk, etc.) with flanges formed of bakelite suitably reënforced. S. RAPPOPORT. Brit. 335,195, June 18, 1929. Structural features.

Warp-sizing apparatus. C. B. JOHNSON. Brit. 335,162, June 13, 1929. Structural features.

Device for singeing fabrics. M. RIPOCHE (to Electro-Textile). Brit. 335,415, Oct 26, 1928. Structural features.

System for treating cotton fibers in and discharging them from digesters by liquids and compressed air. BRITISH BEMBERG, LTD. Brit. 335,457, Dec. 15, 1928. App. and various details of procedure are described.

Washing wool. ELISÉE C. DUHAMEL and COMPAGNIE GÉNÉRALE DES INDUSTRIES TEXTILES. Ger. 513,094, Sept. 4, 1924. See Fr. 665,345 (*C. A.* 24, 977).

Waterproofing cloth, etc. KARL SLABOK and ALEXANDRE PETRENKO. Fr. 691,769, Feb 19, 1930. Cloth, etc., is waterproofed by a bath contg. $Pb(OAc)_2$ and alum and then washed and dried. Suggested proportion for the bath are $Pb(OAc)_2$ 65–70 and alum 35–30%.

Preparation for airplane wings. I. G. FARBENIND. A.-G. Ger. 512,526, June 27, 1929. The textile coverings of the wings are soaked in or coated with polymerized butadiene hydrocarbons or their derivs. or transformation products.

Metallized dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 691,974, Mar. 15, 1930. See U. S. 1,783,083 (*C. A.* 25, 1095).

Metallized dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 691,973, Mar. 15, 1930. Metallized azo dyes are prepd. by treating with agents liberating metals, azo dyes obtained by coupling 5-nitro-2-diazo-1-phenol and its ring substitution products with 1,8-aminonaphtholsulfonic acids in which the sulfo group is in position 4, 5 or 6 and one of the H atoms of the NH_2 group may be replaced by an acyl group. Several examples are given.

Sulfur dyes. I. G. FARBENIND. A.-G. (Fritz Ballauf, inventor). Ger. 511,746, Oct. 27, 1928. Nitro or amino compds. of indole or dihydroindole are treated with S or polysulfides. Thus, nitro-2-methylindole is heated to 220° for 10 hrs. with S, and then for a short time with Na_2S at 100° to give a heat-fast yellow-brown dye. Other examples are given.

Sulfur dyes. I. G. FARBENIND. A.-G. (Erwin Kramer, Bernhard Bollweg and Ludwig Zeh, inventors). Ger. 513,229, Sept. 1, 1927. Red and orange dyes are prepd. by treating the dye described in Ger. 510,484 (*C. A.* **25**, 1096) with alkylating, arylating, or aralkylating agents. The treatment may be effected in substance or on the fiber. Examples are given.

Sulfuretted dyes. CHEMISCHE FABRIK VORM. SANDOZ. Brit. 335,297, July 6, 1929. Dyes giving brownish red, red, reddish violet and violet shades are formed by heating hydroxylated azines (such as aminohydroxyphenazine, aminohydroxytolazine, aminohydroxytolazinecarboxylic acid, dichloroaminohydroxytolazine or ethosafraninone) with alkali polysulfides in the presence of Mo or Mo compds. (suitably under pressure or in the presence of glycerol or alc.).

Dyes of the thioindigo series. I. G. FARBENIND. A.-G. Brit. 334,878, May 11, 1929. Stable reduction products which are insol. or but slightly sol. in aq. alkali are obtained from 4,4′-dimethyl-6,6′-dihalothioindigo by the action of a reducing agent (other than a hydrosulfide) such as Na hyposulfite in the presence of a smaller quantity of an alk. substance such as NaOH, KOH, Na_2CO_3 or NH_3 than used in practice for vatting the dyes.

Dyes of the thioindigo series. I. G. FARBENIND. A.-G. Brit. 334,919, May 11, 1929. Stable reduction compds. of 4,4′-dimethyl-6,6′-dihalothioindigo as described in Brit. 334,878 (preceding abstr.) are made by treating the dyes with alkali and a reducing agent (other than a hydrosulfide) and causing an acid such as CO_2 or SO_2 to act on the soln. thus obtained. Reduction may be facilitated by adding an alc. Brit. 334,920 relates to the application of a similar treatment to 6,6′-diethoxythioindigo

Acid wool dyes. I. G. FARBENIND. A.-G. (Klaus Weinand, inventor). Ger. 511,043, Feb. 26, 1929. See Brit. 332,203 (*C. A.* **25**, 214)

Mordant for dyeing. EUGÈNE JANNIÈRE. Fr. 692,015, Mar. 15, 1930. A mordant for redyeing used cloths consists of 2 powders, the first contg. powd. Florentine iris 12, tellurine 20, trioxymethylene or CH_2O 60.7, MnO_2 or other deriv. of Mn 12.5 and AcOAm 2 parts, the second contg. $FeSO_4$ 40, oxalic acid 40 and $CuSO_4$ 30 parts. The 2 powders are mixed for use in about equal proportions.

Lakes. E. I. DU PONT DE NEMOURS & Co. Brit. 334,874, March 8, 1929. Oil and water-insol. lakes of azo dyes are prepd. by incorporating a metallic compd. such as $CaCl_2$, $BaCl_2$ or a salt of Mg, Pb or Cu in a mixt. of an azo dye of acidic character and a rosin soap in an aq. medium, to form a ppt. of the metallic compds. of rosinate and azo dye in which the rosinate is present to the amt. of 5–60% of the product. Various details, examples and modifications of the process are described.

Diazoamino compounds. I. G. FARBENIND. A.-G. (Winfrid Hentrich, Ernst Tietze, Anton Ossenbeck and Peter Baches, inventors). Ger. 513,209, July 15, 1928. New diazoamino compds. *useful in dyeing and printing* are prepd. by the reaction of aromatic diazo compds. with amines of the C_6H_6 series contg. one SO_3H and one COOH group, or a plurality of COOH groups. The alkali salts of the products are readily sol. in water, and are reconverted to the initial materials on acidification; they are stable to alkalies, warming and rubbing. Numerous examples are given. Cf. *C. A.* **25**, 1099

Acid amides of 7-amino-1,4-naphthoquinone. KARL SCHIRMACHER and KONRAD RENN (to General Aniline Works). U. S. 1,789,884, Jan. 20. Acid amides of 7-amino-1,4-naphthoquinone are formed by treating an acid amide of 7-amino-1-hydroxynaphthalene in an HOAc soln. with chromic anhydride at a temp. of about 0°. Details are given of the prepn. of 7-acetamido-1,4-naphthoquinone (decompg. above 205°), 7-benzoylamino-1,4-naphthoquinone (decompg. above 200°), a corresponding deriv. from 7-*N*-*p*-toluenesulfonylamino-1-hydroxynaphthalene, and the Na salt of 7-benzoylamino-1,4-naphthoquinone-3-sulfonic acid. These compds. may be *used in dye manuf.*

Sulfonic acids. I. G. FARBENIND. A.-G. (Alfred Thauss, Gustav Mauthe and Arnold Doser, inventors). Ger. 513,463, Nov. 1, 1927. *Sulfonic acids useful as assistants in dyeing and printing* are prepd. by condensing a sulfonated aromatic hydroxy compd. with an aralkyl halide at a temp. not exceeding 100°. The reaction is effected in concd. H_2SO_4 soln. while stirring. Examples are given.

Drying colors, pastes, etc. FRITZ HAAS. Fr. 690,954, Feb. 28, 1930. Colors or like gelatinous or pasty substances are dried by alternate admission of dry and moist air.

Dyes. D. A. W. FAIRWEATHER, J. THOMAS and SCOTTISH DYES, LTD. Brit.

334,902, March 7, 1929. Sulfuric esters, apparently tetrasulfuric esters of tetrahydrodianthraquinoneazines, are formed by oxidation in the presence of an alkali of a disulfuric ester of 2-aminoanthrahydroquinone or a substitution product having the 1-position free and isolating the product (suitably by salting out) without allowing the medium to become substantially acid.

Dyes. W. SMITH, S. G. WILLIMOTT, J. THOMAS and SCOTTISH DYES, LTD. Brit. 334,872, March 5, 1929. 2-Benzoylbenzoic acids are condensed with anthraquinones by means of an amino group in the one and a halogen atom in the other, the amino group or halogen being in *o*-position to a nitro group; *e. g.*, 4'-chloro-3'-nitro-2-benzoylbenzoic acid methyl ester is condensed with 1-aminoanthraquinone by heating in $PhNO_2$ in the presence of Cu bronze and Na_2CO_3, forming a brown product which is suitable for dyeing wool or cellulose acetate rayon, or 4'-amino-3'-nitro-2-benzoylbenzoic acid methyl ester is condensed with 1-chloroanthraquinone in the presence of $PhNO_2$, $MgCO_3$, NaOAc and Cu powder. Cf. *C. A.* **24**, 243.

Dyes. I. G. FARBENIND. A.-G. Brit 335,043, June 28, 1929. α-Hydroxyanthracene is condensed (suitably in PhCl) with a 4-methyl-5-halo-7-alkoxyisatin α-deriv. such as 4-methyl-5-chloro- or 4-methyl-5-bromo-7-methoxyisatin α-chloride, forming vat dyes giving bluish green tints fast to light. Details for making the intermediates are given.

Dyes. SCOTTISH DYES, LTD. Ger. 512,820, Dec. 29, 1927. See Brit. 293,328 (*C. A.* **23**, 1651).

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 691,971, Mar. 15, 1930. Dyestuffs are prepd. by condensing dinitrostilbenedisulfonic acid or dinitrodibenzyldisulfonic acid or the products obtained by the action of alkalies upon *p*-nitrotoluenesulfonic acid, in a closed vessel under pressure with aminoazo dyes and in a general way with aromatic substances contg. at least one NH_2 group. The products are different from those obtained in an open vessel, giving deeper shades and being faster to alkalies and light. The products may be submitted to oxidizing agents or to agents liberating metals. Several examples are given.

Azo dyes. I. G. FARBENIND. A.-G. (Erwin Hoffa and Erwin Thoma, inventors). Ger. 512,894, Mar. 11, 1928. A new azo dye is produced by diazotizing 1-amino-2-methyl-4-alkoxy-3,5 dihalobenzene and coupling with the β-naphthylamide of 2,3-hydroxynaphthoic acid. An example is given.

Trisazo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 691,844, Mar. 13, 1930. Trisazo dyes contg. at least 2 SO_3H or COOH groups or one of each and suitable for dyeing viscose silk are prepd. by tetrazotizing 3,4' diaminoazobenzene or a substitution product thereof, and coupling with 2 mol. proportions of the same or different coupling components. Some of the products may be obtained by diazotizing 3-nitro-4'-aminoazobenzene, coupling with a SO_3H or COOH deriv. of a phenol, a naphthol, a naphthylamine or a *N*-substituted aminonaphthol, reducing the NO_2 group, diazotizing and coupling with a suitable component. Several examples are given. The 3,4 diaminoazobenzene and its derivs. are obtained by coupling a diazotized *m*-nitroamine with amines of the benzene series coupling in *p*-position to the NH_2 group, and reducing the NO_2 group.

Azo dyes. SAMUEL MORGOULEFF. Fr. 692,148, June 10, 1929. Azo dyes are made by diazotizing sulfonated or unsulfonated amines and coupling with naphthol or a sulfonated or other deriv. thereof, the diazotization and coupling taking place in the same vat where all the elements are present, the coupling taking place as the diazo compd. is formed. Examples are given.

Chromium compounds of azo dyes. I. G. FARBENIND. A.-G. Brit. 335,169, May 16, 1929. Cr compds. of chromable azo dyes contg. groups such as sulfonic, carboxylic or sulfamide groups, which induce ready soly., are formed by treating the dyes with chroming agents such as Cr chloride in the presence of an org. base such as dimethylaniline, aniline, hexahydromethylaniline or pyridine. The manuf. of the dye and the chroming may be effected in a single operation. Numerous examples are given. Cf. *C. A.* **24**, 1746.

Tetrakisazo dye. GEORG WOLFSLEBEN (to General Aniline Works). U. S. 1,780,888, Jan. 20). A black tetrakisazo dye is formed by coupling 2 mol. proportions of *p*-diazoacetylaminobenzene with 1 mol. proportion of the disazo dye obtainable from 1 mol. proportion of tetrazotized benzidine by acid coupling with 1 mol. proportion of 1-amino-8-naphthol-3,6-disulfonic acid and subsequent alk. coupling with 1 mol. proportion of *m*-phenylenediamine, and saponifying the resulting tetrakisazo compd. The dye is suitable for dyeing chrome leather and may also be obtained by employing, instead of *p* aminoacetanilide, *p*-nitroaniline, in which case the dye is subjected to reduction

instead of to saponification. In most cases, however, the product is obtained in this way with a smaller yield and in a lower state of purity. Details of procedure for making the dye are given.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Erich Berthold, inventors), Ger. 511,239, Oct. 20, 1928. New vat dyes are prepd. by treating alkyl, aryl or other ethers of pyranthrone with halogenating agents. The products yield bluer or yellower shades than the initial materials. Examples are given.

Vat dyes. I. G. FARBENIND. A.-G. (Robert Berliner, inventor). Ger. 513,045, May 9, 1928. See Brit. 311,283 (*C. A.* **24**, 971).

Vat dyes. I. G. FARBENIND. A.-G. (Heinrich Neresheimer, inventor). Ger. 513,046, May 4, 1929. Vat dyes are prepd. by treating anthraquinonyl-4'-amino-1,2-benzanthraquinones with condensing agents. The colors given by the products vary with the condensing agent used, and also according to whether the initial material is further substituted or not. Thus, α-anthraquinonyl-4'-amino-1,2-benzanthraquinone (prepd by condensing 4'-bromo-1,2-benzanthraquinone with 1-aminoanthraquinone) yields a yellow vat dye when heated with dil. H_2SO_4 or $NaAlCl_4$, but a green-blue dye when treated with $AlCl_3$ in the presence of a tertiary base, or fused with KOH. Examples are given Cf. *C. A.* **25**, 824.

Vat dyes. I. G. FARBENIND. A.-G. (Fritz Baumann, inventor). Ger. 513,227, Mar. 15, 1928. Red to brown vat dyes are prepd. by treating α-amino-1,1'-anthrimidocarbazole or its derivs. with haloanthraquinones or their derivs. The reaction may be effected in a high-boiling org. solvent in the presence of an acid-binding agent and a catalyst, *e. g.*, Cu. Examples are given. Cf. *C. A.* **25**, 824.

Vat dyes. I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors), Ger. 513,228, Oct. 21, 1928. Violet, blue or green-black vat dyes of the formula RN(X)C(O)R', where R is a dibenzanthrone or isodibenzanthrone residue, X is H or an alkyl group or other radical, and C(O)R' is the residue of a polynuclear acid, are prepd by treating nitrogenous derivs. of dibenzanthrone or isodibenzanthrone, in which at least one replaceable H atom is linked to the N atom, with halides, anhydrides or esters of polynuclear carboxylic acids, *e. g.*, acids of the anthraquinone, benzanthrone, perylene, pyranthrone, anthanthrone, dibenzopyrenequinone or *ms*-anthradianthrone series Alternatively, halodibenzanthrones or haloisodibenzanthrones may be reacted with amides of the acids. The reaction may be effected in a high-boiling solvent in the presence of an acid-binding agent and a catalyst, *e. g.*, CuO. Examples are given. Cf *C. A* **25**, 1093, 1094.

Vat dyes. I. G. FARBENIND. A.-G. (Albert Schaeffer, inventor). Ger. 513,310, Oct. 3, 1926. Black vat dyes fast to Cl are prepd by mixing a nitrodibenzanthrone with the products obtained by fusing an aminohalobenzanthrone with caustic alkali as described in Ger. 445,845. Dibenzanthrone may be included in the mixt An example is given.

Vat dyes. I. G. FARBENIND. A.-G. (Walter Mieg, inventor). Ger. 513,475, June 26, 1928. Dianthraquinonylaminocarbazoles, which contain at least 1 acridone ring and at least 1 acylamino group, are converted into new vat dyes by splitting off the acyl residue of the acylamino group. The conversion of the dianthraquinonylamine into the carbazole deriv. and the removal of the acyl group may be effected in one working operation. Examples are given. Cf. *C. A.* **25**, 824.

Anthraquinone vat dyes. I. G. FARBENIND. A.-G. Brit. 335,014, Aug. 7, 1929. For producing anthraquinone vat dyes, the products obtained by the action of aminoanthraquinones on 5,8-dihalo-1,2-benzanthraquinones (as described in Brit. 334,565 (*C. A.* **25**, 1094)) are treated with condensing agents (suitably by heating with $AlCl_3$ in pyridine). Examples are given of the production of dyes giving brown shades on cotton

Vat dyes of the anthraquinone series. MAX A. KUNZ, FREIHERR G. VON ROSENBERG and EDUARD GOFFERJE (to General Aniline Works). U. S. 1,790,102, Jan. 27. Vat dyes of various colors and which have the general formula —C^1.N:CA.O.C^2— where C^1 and C^2 belong to an anthraquinone nucleus, A indicates another anthraquinone radical and where both anthraquinone nuclei may be substituted or not are obtainable in a variety of ways. *E. g.*, they are formed when aminoanthraquinones which contain a neg. substituent such as a hydroxyl group or a halogen atom in *o*-position to the amino group, are condensed with anthraquinonealdehydes in the presence or absence of solvents and preferably at an elevated temp. Instead of anthraquinonealdehydes there may be used other anthraquinone derivs. with aldehyde properties, for instance, anthraquinoneisoxazoles, or anthraquinonecarboxylic acids or compds. reacting like them such as the acid halides, esters and similarly acting compds. The new products may also be obtained by condensing anthraquinones containing 2 neg. substituents in *o*-position to each

other with anthraquinonecarboxylic acid amides. A modification of prepg. the new anthraquinoneoxazoles consists in condensing anthraquinonecarbonylaminoanthraquinones which are substituted by hydroxyl groups or other neg. substituents in the *o*-position to the amino group; the said anthraquinonecarbonylaminoanthraquinones may be obtained in advantageous manner by condensing an anthraquinonecarboxylic acid halide with an aminoanthraquinone contg. a hydroxyl group or other neg. substituent in *o*-position to the amino group. Numerous examples are given. Cf. *C. A.* 25, 214.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Qualities of red lead required for practice. JAROMÍR HERITES. *Chem. Listy* 24, 218-20(1930).—Red lead from 3 sources was used: Source (1) contained 29.65% PbO_2, possessed an av. particle size 0.7–15.5μ, and a covering power of 250 sq. cm. per g. Source (2) contained 29.88% PbO_2, possessed an av. particle size of 0.8–27.9μ and had a covering power of 85 sq. cm. Source (3) contained 33.55% PbO_2, possessed an av. particle size of 1.0–24.8μ and had an av. covering power of 133 sq. cm. The covering ability depends not upon the PbO_2 content but upon the size of the particles. This is confirmed by sedimentation tests in glycerol (1:99). Red lead from sources (2) and (3) settled out completely in 12 hrs.; source (1) remained dispersed for over a week. The sediment from source (1) after settling a month was readily redispersed and showed no tendency toward hardening or crust formation. For even films, a heterodisperse system in which a variation of particle sizes occurs is most favorable for forming uniform films. An irregular settling occurs: The most coarse particles settle out first, the finer particles fill the spaces in between. The fixation of the pigment becomes complete and the covering power is increased. When applied upon an inclined plane red lead from source (2) and (3) ran down and tore the film while that from source (1) remained in an even layer and showed no tears. Procedures for analyses are given in detail. FRANK MARESH

The paint and varnish industry in 1930. R. S. MORRELL AND W. E. WORNUM. *Ind. Chemist* 7, No. 72, 29–31(1931). E. H.

New tendencies in body-color manufacture. HANS WAGNER. *Kolloid-Z.* 54, 132–7(1931).—A review of recent patents. A. FLEISCHER

Oxide of iron pigments. F. C. BERLING. *Can. Chem. Met.* 15, 16–8(1931).—The natural and manufd. oxides of iron are discussed and (1931) tests and assays of the various oxides are outlined. W. H. BOYNTON

Titanium white. TORBJØRN HANSSEN. *Teknisk Ukeblad* 75, 88–92(1928).—Comparative tests show the superiority of titanium white over other white paints with regard to covering properties, economy and durability. C. A. ROBAK

New rust-preventive pigments as substitute for red lead. JUL. F. SACHER. *Chem.-Ztg.* 54, 781-2(1930).—The pigments ordinarily used as rust preventives are listed in order of their rust-resisting qualities. Red lead possesses the disadvantage of being poisonous and being difficult to cover with other paints. A new lead pigment has appeared under the trade name "Arcanol." It exists partly in the metallic state and partly as an oxide. Paints made from this material dry in 8 hrs. at 0°, possess qualities of high covering power, great expansibility and are very resistant to the action of hot water or steam. A new oil-free rust-preventive paint suitable for use in the tropics dries only by evapn. of the solvent. It is impermeable to air, water or vapors, and resistant toward sea water, hot vapors, flue gas, acid vapors, stable toward cold and is unaffected by temps. from 200° to 250°. Numerous uses are suggested for this material. H. M. STARK

Liquid absorption by pigments of different types of organic liquids. I. Relation of liquid absorption with a series of organic liquids to interfacial tension of these liquids against water. F. E. BARTELL AND A. HERSHBERGER. *Ind. Eng. Chem.* 22, 1304–9 (1930). The liquid absorption values of SiO_2, $BaSO_4$, CaF_2, $PbCrO_4$, ZnO, lithopone, ZnS, Sb_2S_3 (pptd.), Sb_2S_3 (natural), PbS, FeS, HgI_2, Fe, Zn, Sb, Si, Cu and carbon have been measured with H_2O, iso-BuOH, BuOAc, $CHCl_3$, C_6H_6, CCl_4, *o*-C_6H_4Br and $C_2H_2Br_4$. These have been correlated with the interfacial tension of the liquids against H_2O. The results show that the liquid absorption values of zero contact angle liquid with polar solids increase linearly with increase of interfacial tension against water. With non-polar solids there is a linear decrease. Heating and evacuation have practically no influence on an air-dried powder, but the liquid absorption values

are roughly proportional to the sp. surface. For solids of the same particle size it is found that the sulfides are less highly wetted than $BaSO_4$, CaF_2 and SiO_2. H. C. D.

The theory of drying (of oils) and of antioxygen action. G. DUPONT. *Bull. inst. pin* **1930**, 285–8.—According to Genthe (*Z. angew. Chem.* 1906) the oxidation of linseed oil, in both presence and absence of catalysts, is always due to autocatalysis; induced oxidation does not take place in linseed oil, but only oxidation catalyzed by the products of oxidation themselves. D. shows that this theory is in agreement with the results of his own work and that of his co-workers (*C. A.* **24**, 855, 1386, 1629, 2945, 4209, 4693). A. PAPINEAU-COUTURE

Turpentine oil frauds. J. CAPUS. *Compt.-rend. acad. agr. France* **16**, 1061–9 (1930).—Turpentine oil substitutes in paints come from either mineral or vegetable origin. The mineral substitute is a distn. product of petroleum and is known as "White Spirit." It is inferior to turpentine in that the resulting paint is not as durable and in white paints particularly it soon causes a yellowish discoloration. While substitutes from the vegetable origin contain chem. compds. of the terpene family they do not have the qualities of the fresh oil. Neither of these types of substitutes is found satisfactory and precautions should be taken against their indiscriminate use. J. R. ADAMS

Cobalt driers. E. GEBAUER-FUELNEGG AND GOTTFRIED KONOPATSCH. *Ind. Eng. Chem.* **23**, 163–5(1930).—With the hope of getting an insight into the action of siccatives, simple Co compds. of definitely known structure were prepd. and tested as catalysts on China wood oil. Their solns. in org. solvents are efficient driers in a number of cases. Some such siccative solns caused the formation of glass-clear films of China wood oil. A table is given showing the Co compds. and the solvents used. The photomicrographs of the dried films are characteristic of each of the solvents used. Possible explanations are offered of the phenomena encountered. E. GEBAUER-FUELNEGG

Dangers in work with cellulose lacquers and their prevention. BANIK. *Zentr. Gewerbehyg. Unfallverhütung.* **16**, 197–206(1929); *U. S. Pub. Health Eng. Abstracts* **10**, IHS, 5(Dec. 6, 1930).—A full discussion is given of the nature of the nitrocellulose solvents used in spraying automobiles, railroad cars, etc. These solvents and thinners constitute 30–60% of the lacquer. The thinners may be benzine, C_6H_6, toluene, xylene and alcs. When a rapid drying is required, MeOAc and EtOAc are usually used. However, BuOAc, AmOAc, hexalin acetate and its 3 Me derivs. are also frequently encountered. With the exception of benzene, the destructive action of which on the blood-forming tissues is well known, no serious effects from the other substances were observed. Headache and giddiness, oppression of the chest, and dermatitis from the removal of the fat from the hands leading to dryness and cracking are the main results. Stress is laid on the discomfort experienced by workers in the atm. of spray in poorly ventilated work rooms. Control methods are outlined. C. R. FELLERS

Ethylcellulose dope. I. TSURUO ARAKI AND TEIJI NAGAMOTE. *J. Soc. Chem. Ind. Japan* **33**, Suppl. binding, 382(1930).—The authors tried to use benzene-sol. ethylcellulose for airplane dope and detd. the soly. ranges for several solvents and thinners. It is easily sol. in benzene or toluene but the soln. appears turbid. With 3.5 to 37.5% alc. present the soln. is clear. A suitable mixt. for undercoating of airplane fabric was: benzene 60 cc., methanol 13 cc., benzyl alc. 2 g., ethylcellulose 12 g. **II.** *Ibid* 382–3.—The properties of ethylcellulose dope are given. No appreciable change occurs in the dope soln. during $1^1/_2$ yrs.' storage. The film of the tested sample is of a tensile strength of about 5 kg./sq. mm., and is a little more inflammable than the acetylcellulose film, but not dangerous as the nitrocellulose film. H. M. STARK

Detection of synthetic resin in Peru balsam. J. KOK. *Pharm. Weekblad* **68**, 32–3 (1930).—The reaction is much more delicate when the residue obtained by evapg. the petr. ether ext. is treated with HNO_3 without mixing, so that a green or reddish brown ring is formed. A W. DOX

The constitution of phenol-formaldehyde resin. FRITZ POLLAK AND FRANZ RIESENFELD. *Z. angew. Chem.* **43**, 1129–32(1930).—In order to arrive at the structure of Novolak, a product of condensation between CH_2O and PhOH, the reaction between *β*-polyoxymethylene (I) and PhOH was studied quantitatively. It was found that 6 mols. of I react with 7 mols. of PhOH with the formation of a viscous resin, completely sol. in EtOH; 6 mols. of H_2O were also evolved. By action of water or NaOH, 2 mols. of phenol are split off. These facts suggest the formula *1,4-*$HOC_6H_4CH_2$-$(C_6H_3(OH)$-CH_2-$)_3$-C_6H_4OH. Increasing the quantity of I slightly above the required amt. results in a gelatinous product, signifying that the various products obtained from PhOH and CH_2O may be isomeric and not substances of various mol. wts. I. M. LEVINE

Paints, plastic materials. ERNST KRAUSE and F. WILHELMI A.-G. Fr. 690,987, Mar. 3, 1930. Paints or plastic materials of high mech. and chem. resistance are prepd. by treating fossil resins such as copal or amber with an alk. soln. in the presence of org. solvents and assocg. them in the dispersed phase or after pptn. and resoln. in org. solvents, with esters or ethers of cellulose.

Bactericidal paint. LACKWERKE JAPONIKA GES. Brit. 335,242, June 19, 1929. An oil paint or varnish or "cellulose" or resin coating compn. has added to it a phenolic deriv. of an aromatic hydrocarbon (other than carbolic and cresylic acids) such as phenol homologs with branched side chains or phenols of condensed nuclei, and the pigments used are preferably acid or neutral, such as titanic acid or Zr oxide.

Corrosion-resistant paint. HANS LANDMARK. Norw. 45,727, Oct. 22, 1928. Fine magnetite slime is mixed with linseed oil.

Pigments. FRANK RAHTJEN and MANFRED RAGG. Ger. 513,338, Sept. 11, 1927. Addn. to 486,974 (*C. A.* **24**, 1528). App. for grinding up metals in a finely divided condition for pigments is described.

Pigments. I. G. FARBENIND. A.-G. Fr. 690,708, Feb. 26, 1930. $Zn(OH)_2$ or ZnO which is pptd. and dried at a temp. not above 500° is used for making pigments as it reacts rapidly with binding agents such as linseed oil. Cf. *C. A.* **25**, 1107.

Titanium pigments. I. G. FARBENIND. A.-G. Fr. 690,764, Feb. 27, 1930. Ti pigments free from Fe are made by washing the ppt. of Ti hydroxide on fillers such as $BaSO_4$ or $CaSO_4$, with cold water and then with dil. acid.

Titanium pigments. I. G. FARBENIND. A.-G. Fr. 691,458, Mar. 7, 1930. Ti oxide hydrate is pptd. from a H_2SO_4 soln. with or without filling materials such as $BaSO_4$, $CaSO_4$, H_2SiO_3, etc. Cf. *C. A.* **24**, 2903.

Lithopone, etc. SOC. ANON. DES PRODUITS CHIM. D'ESTRÉE-BLANCHE. Fr. 690,726, Feb. 26, 1930. Lithopone is tinged with blue or blues having a basis of lithopone or other whites are made by dissolving one or more salts in water in which the pigment is suspended, and adding another salt which will ppt. a blue or violet compd. Such pairs of salts are, *e. g.*, $K_4Fe(CN)_6$ and $Fe_2(SO_4)_3$ or Na_2HPO_4 and $CoSO_4$.

Lithographic printing inks containing cellulose esters and ethers. I. G. FARBENIND. A.-G. Brit. 335,074, Oct. 4, 1929. Inks of the general type described in Brit. 318,567 (*C. A.* **24**, 2316) are formed of water-repelling constituents which may include a cellulose ester or ether, a plasticizer, resins, pigments, etc. Several examples are given.

Duplicating process and ink for use in the process. LEO SILBERTSTROM. U. S. 1,789,783, Jan. 20. For effecting duplication by the "Opalograph process," the characters of the original to be duplicated are formed with an ink contg. $(CH_2)_6N_4$, which serves as a sensitizer and stabilizer.

Paint oils. JOHANNES SCHEIBER. Ger. 513,309, Feb. 21, 1928. See Brit. 306,453 (*C. A.* **23**, 5051).

Linseed oil. ROBERT H. ADAMS and BENJAMIN H. THURMAN (to Gold Dust Corp.). U. S. 1,790,494, Jan. 27. In extg. linseed oil, the whole uncracked flaxseed is cleaned to a maximum of about 1.5% dockage and the oil is pressed out at a temp. below 43°.

Linseed oil. BENJAMIN H. THURMAN (to Gold Dust Corp.). U. S. 1,790,514, Jan. 27. Bleaching of linseed oil free from mucilaginous matter is effected by heating to 260–282° *in vacuo* in the presence of steam and then rapidly chilling to about 95°. Cf. *C. A.* 24, 1753.

Treating wood oil for varnishes, etc. JOHANNES SCHEIBER. Ger. 511,044, July 31, 1928. Wood oil for use in making varnishes, etc., is treated with the amt. of H or Cl required to sat. one of its double bonds. The hydrogenation may be effected at 180° in the presence of Ni as a catalyst. The chlorination may be effected during cooling. Examples are given

Lacs. JOHANNES SCHEIBER. Ger. 512,822, July 31, 1928. The distn. residues of ricinoleic acid and octadecadiene-(9,11)-acid (1) are esterified with polyhydric alcs. Oils, resins, etc., may also be added.

Lacs, etc. JOHANNES SCHEIBER. Ger. 512,895, July 31, 1928. The distn. residues from the vacuum distn. of ricinoleic acid are employed in the manuf. of lacs, paints, etc. The residues may be esterified, and other oils, resins, etc., may be added.

Lacquers. WOLFF & CO. KOMM.-GES. AUF AKTIEN and RICHARD WEINGAND. Ger. 513,424, Apr. 4, 1928. Cellulose-ester bronzing lacquers contg. a powd heavy metal are stabilized by addn. of a small quantity of H_2O_2.

Apparatus for coating metal articles with lacquer, etc. I. G. FARBENIND. A.-G. (Adolf Benischek and Carlos Thode, inventors). Ger. 513,093, Aug. 3, 1927.

Method and apparatus for drying lacquered filaments, wires, etc., under reduced pressure. CARL C. ERDMANN. Ger. 513,408, Oct. 23, 1927.

Plastic compositions. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 691,896, Mar. 14, 1930. A moldable compn. comprises a polymerized drying oil and a fusible phenolic resin which may be made infusible by heat. A fibrous material or other inert filler may be impregnated with the polymerized oil and resin.

Condensation products. I. G. FARBENIND. A.-G. (Max Paquin, inventor). Ger. 510,428, May 10, 1927. Addn. to 506,963 (*C. A.* 25, 835). The method of 506,963 for producing oily or resinous products by condensing urea with alcs. and ketones, or derivs., in the presence of amino compds., is modified by the added presence of reducing metals such as metals of the alkali, earth alkali or Zn groups. Other examples are given. Cf. *C. A.* 25, 835.

Condensation products. I. G. FARBENIND. A.-G. (Max Paquin, inventor). Ger. 512,231, June 25, 1927. Addn. to 510,428 (cf. preceding abstr.). The reducing metal present during the condensation of urea and alcs. or ketones described in 510,428, is treated with CH_2O or CH_2O-generating substances before the reaction. Cf. *C. A.* 25, 835.

Resins. HERMANN GAMMAY. Fr. 690,988, Mar. 3, 1930. A colophony poor in "Resene" is made by distg. pine resin under vacuum with a small quantity of satd. steam, from which a distn. temp. below 110° is obtained.

Conversion products of natural resins. I. G. FARBENIND. A.-G. (Leo Rosenthal, inventor). Ger. 514,151, Oct. 9, 1925. Natural resins are treated in aq. or aq. alk. soln. or dispersion with a halogen or other halogenating agent, *e. g.*, a hypochlorite or hypobromite. The products contain halogen and are still resinous. Examples are given.

Synthetic resins. ALLGEMEINE ELEKTRICITÄTS-GES. Fr. 691,464, Mar. 7, 1930. In making resins from polyhydric phenols and carbonyl compds. an intermediate condensate is formed by adding only part of the necessary carbonyl compd., and afterward the rest of the carbonyl compd. is added to form the final condensate by a distinct operation. The intermediate condensate may be formed in the presence of fillers such as sawdust, asbestos, talc, natural resins and dyes. Examples are given.

Synthetic resins. BAKELITE CORP. Fr. 690,707, Feb. 26, 1930. Resinous compns. are made by condensing a phenol with an excess of aldehyde such as CH_2O in the presence of a basic catalyst such as Na_2CO_3 and afterwards combining the excess of aldehyde with a resin-forming substance, not phenolic, such as urea in the presence of a weak acid such as H_3PO_4. Cf. *C. A.* 25, 1109.

Synthetic resins. BAKELITE, LTD., J. W. CRUMP and A. LLOYD. Brit. 335,173, June 13, 1929. Urea or thiourea, a phenol or deriv. and an aldehyde such as CH_2O are melted together, without the aid of aq. soln., and heated to complete condensation. If the urea preponderates over the phenol, the reaction mixt. must be neutral or alk., but if the phenol preponderates acid, alk. or neutral condensing agents may be used. Resins may be formed which may be ground to a fine powder and are easily fusible

and may be rendered infusible by further heating. Various details of procedure are given.

Synthetic resins. I. G. FARBENIND. A.-G. Brit. 335,185, March 16, 1928. Ketones contg. an aliphatic chain with one double bond only, such as methylenemethyl ethyl ketone, are polymerized in emulsion with an aq. emulsifying agent such as Na oleate (which in 1% soln. after 8 days at 60° yields a bright yellow resin) or with a colloidal soln.

Synthetic resins. IMPERIAL CHEMICAL INDUSTRIES, LTD., W. BAIRD and E. E. WALKER. Brit. 335,292, July 3, 1929. Non-hydroxylated oils such as olive, tung or linseed oils are incorporated with synthetic resins of the polyhydric-alc.-polybasic-acid type by use of a hydroxylated fatty oil such as castor oil as a vehicle (suitably in a single operation with the formation of the resin from materials such as glycerol and phthalic anhydride). Various details of procedure are described.

Phenol-aldehyde resins. CHEMIE & TECHNIK J. M. S. GES. and H. MENZ. Brit. 335,194, June 18, 1929. Pure phenol is boiled with formaldehyde in the presence of an alk. catalyst comprising both Na_2CO_3 and $NaHCO_3$, and HOAc is added after boiling, to retard the setting. If a colored product is desired a portion of the condensed material is allowed to set and is boiled with bone oil or glycerol to dissolve it, and mixed with coloring matter, and then mixed with the other portion of the condensed material (to which HOAc has been added) and may be formed in heated molds.

Molded objects. BOIS BAKÉLISÉ and LA BAKÉLITE. Brit. 334,804, Dec. 7, 1928. See Fr. 665,398 (*C. A.* **24**, 930).

Large receptacles formed in part at least of artificial resins. JOHANN K. WIRTH. U. S. 1,789,642, Jan. 20. Various details of procedure are described for making receptacles by joining different plates or segments. Cf. *C. A.* **24**, 1754.

Artificial resins. I. G. FARBENIND. A.-G. (Otto Schmidt, Karl Seydel and Nikolaus H. Roh, inventors). Ger. 511,092, Oct. 22, 1925. See Brit. 276,518 (*C. A.* **22**, 2475).

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The oils, fats and soap industries in 1930. REX FURNESS. *Ind. Chemist* **7**, No. 72, 13–5(1931). E. H.

Detection of fats by ultra-violet light. J. LENFELD. *Z. Fleisch-Milch-Hyg.* **39**, 451–4, 477–81(1929).—Changes in appearance observed when various edible fats are exposed to the light of the analytical quartz lamp are recorded. Marked differences in fats from the same species were often observed. B. C. A.

Study of oils of marine animals. The fats of the sperm whale. (MLLE.) M. TH. FRANÇOIS. *Thesis*, Paris; *J. pharm. chim.* [8], **12**, 189–91(1930); cf. *C. A.* **21**, 564, 1720, 3278; **22**, 216.—By catalytic hydrogenation of oil of spermaceti, in which oleic alc. (*A*) is the principal constituent (Tsujimoto), large quantities of octadecylic alc. ($C_{18}H_{38}O$) were obtained. Also a method was found of isolating *A* from oil of spermaceti with a yield of 25% by wt. S. WALDBOTT

***o*-Dichlorobenzene, an ideal fat solvent.** J. EHRLICH. *Oil & Fat Ind.* **8**, No. 1, 19–20(1931).—Com. *o*-dichlorobenzene contains 25% of the para-isomer. The boiling range is from 160° to 200° and the d_{25} is 1.309. It is immiscible with H_2O and is stable. The fire hazard is low; the flash point is 67°, but even above this temp. it will not burn if the flame is removed. This compares favorably with the chlorinated aliphatic hydrocarbons in general use. It is volatile with 1.5 times its wt. of direct steam at atm. pressure. It has a great avidity for fats and exts. them completely even from substances contg. an appreciable quantity of H_2O. E. SCHERUBEL

Solvent extraction successfully applied. CLARENCE F. EDDY. *Oil & Fat Ind.* **8**, No. 1, 11–3(1931).—The following points are suggested for efficient large-scale production: (1) Use the simplest app. possible to wash out the max. amt. of oil with a min. of solvent. (2) Distil only the most concd. solns. obtainable. (3) Solvent loss: a tight system with good recovery app. and min. solvent turnover should be used. (4) Use mech. control of flow of solids and liquids. The future of large-scale solvent extn of vegetable oils lies in continuous countercurrent extn. E. SCHERUBEL

Fatty acids of some Indian seed oils: seed fats of Mesua ferrea, Calophyllum inophyllum and Pistacia vera. D. R. DHINGRA AND T. P. HILDITCH. *J. Soc. Chem. Ind.* **50**, 9–12T(1931).—The fatty acids of *Mesua ferrea* (Malabar) had the following

% compn.: myristic 1.8, palmitic 6.3, stearic 10.7, oleic 49.2, linoleic 7.3, unsaponifiable 24.7. These figures correspond with a sapon. no. of 290.9 and an I no. of 73.2 for the actual glycerides present in the oil. The fatty acids of *Mesua ferrea* (Bengal) in % compn. were: myristic 1.4, palmitic 7.5, stearic 9.2, arachidic 1.7, oleic 58.7, linoleic 9.9, unsaponifiable 11.6. The % compn. of the fatty acids of the neutral glycerides of *Calophyllum* seed fat was: palmitic 15.8, stearic 10.2, oleic 49.4, linoleic 24.0, unsaponifiable 0.6. The I no. of the original oil was 92 1 and the sapon. no. 286.6. The % compn. of the fatty acids of *Pistacia vera* as found was: myristic 0.6, palmitic 8.2, stearic 1.6, oleic 69.0, linoleic 19.8, unsaponifiable 0.8. These figures correspond with a sapon. no. of 291.6 and an I no. of 94.7 for the actual glycerides present. E. S.

The fatty acids of oils of jupaty (Raphia taedigera, Mart.), Para chestnuts (Bertholletia excelsa H. B. K.) and cayate (Omphalea diandra Aubl.). A. Callier. *Bol. esc. chim. (Belem)* 1930, No. 1, 17–25; *Chimie & industrie* 24, 930.—Oil of jupaty has d_{15} 0.917, sapon. no. 194, I no. 77, acidity (as oleic) 19.2%; the fatty acids consist of 33% solid acids (almost exclusively palmitic) and 67% liquid acids (80% oleic and 20% linolic). After decolorization it is suitable for *soap making*. Oil of Para chestnuts has d_{15} 0.918, sapon no. 193, I no. 102, acidity (as oleic) 1.4–1.7%; the fatty acids consist of 25% solid acids (almost exclusively palmitic) and 75% liquid acids (75% oleic and 25% linolic). It is a semi-drying oil and is suitable for use in *fine paints* and as a *food*. Oil of cayate has d_{15} 0.919, sapon. no. 192, I no. 109–116, acidity (as oleic) 0.7%; the fatty acids consist of 20% solid acids (almost exclusively palmitic) and 80% liquid acids (60% oleic and 40% linolic). It is suitable for use in *perfumery* and for the *lubrication of fine machinery*. A. Papineau-Couture

Twitchell reagent. VII. Darkening of fatty acid obtained by Twitchell process. I. Kyosuke Nishizawa and Kiyota Fuzimoto. *J. Soc. Chem. Ind., Japan* 33, Suppl. binding 500–4(1930).—The color of olive oil refined with 60° Bé. H_2SO_4 was studied after treatment with 7 reagents of different types. It was found that the addn. of H_2SO_4 is not the reason for the darkening of fatty acids obtained by the Twitchell process. All reagents increase the depth of color of fatty acids with increase in time of heating; the presence of air also increases the color Exptl. work was done with the following reagents: Idrapid, Divulson, Kontakt, Pfeilring. Twitchell (benzene) (Naphthalein) and (phenol). E. Scherubel

Results of recent experiments in oil milling. M. K. Thornton, Jr. *Oil Miller & Cotton Ginner* 36, No. 6, 15–8(1930).—The effects of varying amts. of hulls added to the meats before cooking were detd and no effect on the color of the oil was noted In expts. on cooking, a temp. of 215–25° F. was found best for quality oil production In pressing, the hotter the press boxes were, the harder the cake was, and the hotter the meats were when put in the boxes, the harder the cake was. Excess moisture resulted in a softer cake. J. E. Laita

Influence of various conditions on the preservation of crude oil obtained by pressing soy bean. V. M. Suichov. *Chinese East Ry, Ltd., Dept. Trans. Agr. Branch* 1928, No. 8, 3–116; *Chimie & industrie* 24, 929–30.—The investigation was carried out on a sample which had been kept for a long time and on one taken directly from the filter press. Least variation of d. occurs in oils kept in a dark damp place; sunlight increases the d., and the increase continues for some time after the oil is placed in the dark. Addn. of 10% H_2O favors constancy of the d. The d. of the dried oil varies quite rapidly, and neutrality of the oil apparently is of no consequence. The viscosity of the oil increases with the d.; the increase is most rapid in elec. light. The oil is decolorized in sunlight and in elec. light, the rate of decolorization depending on the intensity of the light Neutralization, increase in temp. and the presence of air accelerate the rate of decolorization. The presence of non-fatty impurities, water and heat prevent decolorization. Increase in acidity is due somewhat to the action of sunlight, but chiefly to fungi In order to prevent excessive acidity and decompn. of the oil, it should be filtered and protected from the air which is present in the crude oil and causes its decompn. The sapon. no. and proportion of alc. acids increase on exposure to sunlight, elec. light and heat; filtration overcomes these defects The presence of insol. impurities in the oil increases the free acidity, the I no. and the tendency to decompn.; it decreases the sapon. no., the rancidity, the d. and the viscosity. In order that the oil may keep well, it should not contain any insol. org. impurities, the H_2O content should not exceed 0.2% and the container must be clean. A. P.-C.

Reagent for the determination of the acidity of soy-bean oil. N. I. Morozov *Chinese East Ry, Ltd., Dept., Trans. Agr. Branch* 1928, No. 7, 38–44; *Chimie & industrie* 24, 924(1930).—Dil. 10 cc. of satd. fuchsin soln. to 100 cc. with distd. H_2O, boil 30 min. to remove CO_2, add a 10% NaOH soln. to yellowish color, dil. to 100 cc., ext.

in a sepg. funnel with 100 cc. benzine. The reagent is the benzine soln. of fuchsin. The acidity of the oil is detd. by adding 1 cc. of reagent to 5 cc. of sample and comparing the color with that of standard oil solns. A. PAPINEAU-COUTURE

Effect of the humidity of circulating air upon the rate of absorption of moisture in cotton seed. M. K. THORNTON, JR., AND P. P. BRIGGS. *Oil Mill Gaz.* **33**, No. 6, 15–25 (1929).—Data, curves, conclusions, and equations expressing the relation of the absorption rate to relative humidity are given for humidities ranging from 30 to 100%. The conclusions obtained are: (1) The absorption rate is a function of the humidity. (2) An equil. moisture content is reached with const humidity. (3) Rapid deterioration begins at moisture contents in excess of 11%. (4) Meats, and not hulls, are principally responsible for moisture absorption J. E. LATTA

Rapid determination of moisture in cotton seed. M. K. THORNTON, JR., AND J. E. GRAGG. *Oil Miller & Cotton Ginner* **37**, No. 3, 19–20(1930).—A rapid distn. method for detn. of moisture in cotton seed is described. The sample is distd. with xylene in an app. arranged so that the distn. medium is refluxed, and the water is caught in a graduated sedimentation bulb. A 15-min. distn. removes the free moisture and the per cent moisture is obtained from the rise in water level in the bulb which has been calibrated The results obtained by this method are the same as those obtained by the official method. J. E. LATTA

Variation in samples of cotton seed taken from different parts of a slab. M. K. THORNTON, JR., AND W. T. COLEMAN. *Oil Mill Gaz.* **34**, No. 2, 5–7(1929).—Analyses of samples from different parts of a cake are compared with the analysis of the standard sample. The errors of "spot" sampling are evident from the data given. J. E. L.

Rolling and cooking of cottonseed meats. M. K. THORNTON, JR. *Oil Miller & Cotton Ginner* **36**, No. 4, 15–7(1930).—The rolling of the meats into a fine meal was found to lessen the time and lower the temp. necessary to rupture the oil cells. Also, if moisture in the form of steam is added to the meats during cooking, the cell rupture is aided, the quality of the cake is improved, less decompn. of chlorophyll takes place and the refining loss on the oil is decreased. A finishing temp. of 220°F. was found best for cooking J. E. LATTA

Oil from the seeds of Asteriastigma macrocarpa. D. H. PEACOCK AND CHIT THOUNG. *J. Soc. Chem. Ind.* **50**, No 1, 7–8T(1931).—The oil was obtained by extn. of the grated seeds with benzene and the following consts. were detd.: d_{35} 0.9501, N_{29} 1.4790, α_D^{29} + 52.8°, I no. 112.3, sapon. 195.6, unsaponifiable 3.0%. The oil was found to contain oleic and a satd. acid possibly palmitic, and also chaulmoogric or a mixt. of chaulmoogric and hydnocarpic acids. E. SCHERUBEL

Emulsions (Ger. pat. 512,979) **13.** Machine for the forming of soft soap and other materials of a similar consistency into pieces of fixed weight and shape (Norw. pat. 47,052) **1.** Heat-exchange apparatus suitable for treating oil or other liquids (U. S. pat. 1,790,151) **1.** Apparatus for separating oil, etc., and water (Ger. pat. 511,367) **1.** Purifying higher alcohols (Fr. pat. 690,958) **10.**

Rendering fat-containing materials. STANLEY HILLER. U. S. 1,789,751, Jan. 20. Fat contg. solid animal material is digested under high steam pressures to melt fats and oils, and the digested material is continuously dehydrated in a vacuum to a moisture content below 20%, free hot fats and oils are continuously drained from the dehydrated solids, and the residue is continuously expressed to sep. further fats and oils. App. is described. Cf. *C. A.* **24**, 3669.

Apparatus for melting tallow. GUSTAV HÖNNICKE. Ger. 511,132, April 10, 1929.

Steam distillation apparatus for fatty acids, etc. METALLGESELLSCHAFT A.-G. Ger. 511,641, Feb. 26, 1929.

Purifying fats and fatty oils. I. G. FARBENIND. A.-G. Brit. 335,089, Oct. 21, 1929. For removing slime from materials such as crude sesame, linseed or peanut oils or the like, they are heated to 70–200° with a small quantity of β-naphthalenesulfonic acid or other similar sulfonic acids, and the ppt. formed is filtered off after adding a small quantity of kaolin or the like.

Extracting fatty oils from fish, etc. K. F. WILHELM. Brit. 335,438, Oct. 19, 1929. See Fr. 685,002 (*C. A.* **24**, 5523).

Stabilizing vegetable or animal oils and fats. PAUL I. MURRILL and WALTER W. EVANS (to R. T. Vanderbilt Co.). U. S. 1,789,926, Jan. 20. A small quantity (suitably about 0.2–0.5%) of a condensation product of an aldehyde with an alkylenediaryldiamine such as that of aldol with ethylenediphenyldiamine is added to oils or fats such

as olive oil, etc. U. S. 1,789,927 relates to compns. of the same general character, mixed greases, etc.

Rendering animal oils and fats. The Allbright-Nell Co. Ger. 511,131, June 23, 1926. See Brit. 253,952 (*C. A.* 21, 2569).

Centrifugal separator for animal oils. Soc. Aktiebolaget Separator. Fr. 690,867, Mar. 1, 1930.

Extracting oils by compression. Fried. Krupp Grusonwerk A.-G. Ger. 513,311, Nov. 2, 1929. A device is described for regulating the supply of oleaginous fruits to pans in which they are warmed before pressing.

Medicinal soap. Ludwig Konstandt. Ger. 511,240, Nov. 3, 1929. Calcareous tufa is incorporated into soap contg. colloidal S, to act as a protective colloid for the S.

28—SUGAR, STARCH AND GUMS

J. K. DALE

Steam economics in sugar factories. Jar. Turek. *Listy Cukrovar.* 49, 90–2 (1930).—A survey of sugar establishments shows a range of 4.6 to 9.4 kg. of coal used per 100 kg. of sugar beets. Control steam consumption is discussed. F. M.

The influence of the liquor composition upon coloration during boiling. O. Reiss. *Listy Cukrovar* 49, 41–50(1930) —Four hundred g. of a 15% sucrose soln. was digested so that the concn. progressed from 15° to 60° Bg. in an hr.; this required the removal of 300 cc. water. The residue was made up to the original concn. (15° Bg.), filtered through asbestos and measured for color and p_H. The amount of coloration increased with increasing alky. up to p_H 10.4; neutral or acid solns. showed an insignificant color formation. With an addn. of 0.05% invert sugar, coloration occurred in alk. solns. only; the additional amt. of coloration is directly proportional to the quantity of invert sugar added. With solns. ranging from p_H 4 to 10 and contg. sucrose, invert sugar 0.05% and Na aspartate 0.05%, coloration developed only in the alk. digest. The coloration due to aspartic acid and invert sugar increased 88%; that due to invert sugar alone increased 50% under identical conditions. The additional color is due to nitrogenous dyes formed by the condensation of amino acids and invert sugar. By using a condensation product (prepd. by digesting invert sugar with aspartic acid for several hrs. on a water bath) with the above sucrose digests in 0.05% concns., additional coloration developed even in neutral or acid solns. The coloring matter which developed decomposed further (especially in alk. media) into more intensely colored compds; these hastened the decompn. of sucrose and also of invert sugar. The addn. of 0.02% Na_2SO_3 to the sucrose digest caused less coloration than in the control; it reduced colored substances and blocked aldehydes and ketones. The increase with Na_2SO_3 was 37%; with the control, 50%. The addn. of 0.001% $FeSO_4$ increased the color 85 to as much as 214%; the action is one of catalysis. With an increasing concn of the liquors, the colored pigments increase rapidly; this also applies to repeated evapns. Frank Maresh

The course of the first saturation. II. Commercial trials. J. Dědek and Th. Nielsen. *Listy Cukrovar.* 49, 119–29(1930).—A special arrangement by which the studies could be made on a large scale is described; 63 measurements were made during the active season. The alky. against phenolphthalein falls rapidly up to 0.15% CaO; for greater CaO values, the fall in alky. is very small. Fully 95% of all drops in alky. occur in the first period of satn.; the decrease in alky in the first half of the satn. period is 13.5 more rapid than during the second half. With the passage of Ca into the sediment, a more rapid drop in alky occurs than at the beginning of the satn.; the satn. is not retarded. The final period of satn. is marked by an increase in alky., due to an increased soly. of the pptd. CaO or to a recrystn. of the finely pptd. $CaCO_3$ to coarser grains, leaving a smaller surface area and leading to a reversed adsorption. This leads to a rapid release of adsorbed substances. The apparent dry matter detd. by Balling's method roughly follows the refraction readings. Polarization showed a linear drop during the early stages while the alky. remained const.; the sucrose is combined into an insol. form before the first cloudiness appears in the soln. Curves of elec. cond. are also given. Frank Maresh

Rationalization in the sugar mill and refinery. F. Hamous. *Listy Cukrovar.* 49, 149–50(1930). Frank Maresh

Chemical engineering advances in the cane sugar industry. George P. Meade. *Chem. Met. Eng.* 37, 746–50(1930); *Trans. Am. Inst. Chem. Eng.*, New Orleans Meeting, 1930, 12 pp. (adv. copy).—A review. C. L. Mantell

A preliminary record of some of the more important parasites of sugar cane insects in Negros. W. Dwight Pierce. *Sugar News* **11**, 735–6(1930). V. G. Lava

Means of separating foreign articles from beets. Fr. Paulík. *Listy Cukrovar.* **49**, 150(1930). Frank Maresh

The composition of sugar beets in various crop rotations. A. M. Nadezhdin. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 29–34(1930).—Most of the records obtained were with beets following clover, peas, corn and clean fallow, with or without fertilization. The crop preceding sugar beets exerts a strong influence with respect to the compn. and quantity relations between tops and roots. In this respect the preceding crop exerts more influence than the fertilizers (in the amts. added). By manipulating the fertilization of the sugar beets properly and considering crop rotation effects it becomes possible to influence considerably the compn. of the beet, especially the N and sugar content. J. S. J.

Contribution to the biochemical characteristic of a sugar beet variety. B. A. Rubin, R. V. Feniksova and V. I. Zemskii. *Zhur. Sakharnoi Prom.* **4**, 92–106(1930).—Two varieties were investigated: Yanash—known for its high sugar content—and Khar'kov—known for its yield. For 4 years (1925–28) duplicate samples were taken every month from May through October and analyzed for carbohydrates, total N, protein N, amino acid N, ammonia N, amide N and org. bases. The results are presented in a series of tables and graphs, and the conclusions are summarized. J. S. J.

The use of agricultural and experimental beet studies to increase the efficiency of sugar manufacturing. Jar. Souček. *Listy Cukrovar.* **49**, 25–8(1930).—Sample computations are given in which the quality of beets, area of tilled beets, yield of the crop and method of caretaking are considered in increasing the efficiency of the sugar process. Frank Maresh

The conclusions of V. I. Tovarnitzkii and A. E. Maximovich on the influence of nitrogen on the yield and quality of sugar beets. K. M. Timofeyuk. *Zhur. Sakharnoi Prom* **4**, 89–92(1930).—T. analyzes the conclusions that NH_3 N is not a favorable nitrogenous fertilizer for sugar beets and shows that the p_H of the soil is the controlling factor, not the form of N. J. S. Joffe

The determination of the quotient of purity in beet juices. Frant. Herles. *Listy Cukrovar.* **49**, 139–40(1930).—Fine beet mash (52 g.) obtained from the Herles press is treated with 156.4 cc. H_2O (20°), shaken well in a glass vessel and filtered through paper. The sp. gr. of the filtrate is detd. in a pycnometer or refractometrically. Either 50 or 100 cc. of the filtrate is placed in a volumetric flask, treated with 0.1 of their vol. of a 25% AcOH soln., mixed, filtered and polarized The polarization values give the sugar content in the Schmitz tables. From these data the quotient of purity is obtained. Clarification may be effected with Pb acetate (basic), but the polarization values are decreased about 0.05°. Frank Maresh

Changes in dried sweet cossettes during storage. K. Šandera and C. A. Růžička *Listy Cukrovar.* **49**, 163–6(1930).—Sweet beet cossettes were dried in Eynshan under various conditions. Fluctuations in the range 10–30° caused no change in an 18-month period other than decreasing the reducing substances. Variations in temp. or light had no influence. The atm. humidity had a great effect; in one expt. the whole stock was disintegrated by high humidity. With ventilation, the cossettes retained a faultless appearance and in an 18-month period showed a decrease in the reducing substances when compared with nonventilated stock. To study this decrease, the ventilation rates were changed at various temps.; the entrance of air decreased the content of reducing substances (9% during the first 6 hrs.). The ventilation expt. explains the drop observed in the temp. fluctuation expt. and the experience with drying bins working with large excess of air. Frank Maresh

Notes on various methods of heating beet cossettes ahead of the diffusion battery. J. Zamaron. *Bull. assoc. chim. sucr. dist.* **47**, 442–6(1930).—The various methods of heating beet cossettes prior to and during the diffusion process are reviewed. Z does not consider any of the new processes of continuous diffusion as completely successful, the juices obtained being too dil., or the extn. irregular or insufficient. F. C.-C.

The conductometric determination of ash in raw sugar. K. Šandera. *Listy Cukrovar.* **49**, 21–5(1930).—Questionnaires show that the cond. method and interpretation of results are uniform in Czechoslovakia. The method is compared with procedures used in other countries and is recommended: (1) to replace the combustion method, (2) to obtain a new const. from the detn. of the abs. cond. which will be characteristic for each sugar. (3) to det. inorg. cations in raw sugar instead of an ash detn. Frank Maresh

The use of a single conductivity determination of salts (ash) in raw sugar. K. ŠANDERA. *Listy Cukrovar.* **49**, 151–61(1930).—The use of a technical cond. method is compared with visual indicators. In all detns., a soln. contg. 26 g. sucrose per 100 cc. H_2O was used; the results are computed as percent of sulfate ash and corrected. A correction coeff. computed for results obtained with Lange's method was 2.64×10^{-2}, for Trenkler's 2.66×10^{-2}. For other methods, obtained on foreign sugars, these coeffs. were higher: 2.80–2.90 for Lange's detns., 2.94 for Lundén's; this indicates that Czechoslovakian inorg. nonsugars show an av. higher cond. than those of German and Swedish raw sugars. A diagram is constructed showing graphical results for Zerban's method. From the characteristic cond. consts. the abs. cond. and Lundén's consts. m and n were computed for raw sugars of the 1929–30 season. A direct and consistent const. (n) among the sugars tested did not exist; the av. value was around 8.80. After the cond. is calcd., a table is given for detg. the abs. cond. to 4 decimal places. FRANK MARESH

The use of conductivity methods for the official determination of ash in raw sugars. J. PUCHERNA. *Listy Cukrovar.* **49**, 161–2(1930).—P. has used the Šandera cond. method for detg. ash on samples of sugar arriving at the refinery; ash is detd. at the mill gravimetrically on departing specimens. On the basis of a 2-year period of com. application, P. finds an abs. agreement between the detns. by the 2 methods in 18% of the detns. In 84% of the detns., the variation did not exceed ±0.03%; in 6% of the cases the difference exceeded ±0.04%. In 70.5% of the detns., the variation did not exceed 0.02%. These com. tests agree with the lab. tests of Herles, Šandera, etc. Errors were found to be greater with the gravimetric method than with the cond.; errors in the gravimetric method are due to mech. contamination of the samples. FRANK MARESH

An improved method for removing foam from continuous "Malaxers." FR. PAULÍK. *Listy Cukrovar.* **49**, 140–2(1930).—Angular troughs are described which collect the foam from the surface into a central container. FRANK MARESH

The contamination of pure sugar solutions by the material of the vessels. J. PELLER. *Listy Cukrovar.* **49**, 143–7(1930).—The soly. of glass in a 26% sucrose soln is 3.5 times as great as in H_2O. Studies were carried out at 20° and 100° and with 10, 26 and 45% sucrose solns. The soly. of glass increases with concn. of sucrose both at 20° and 100°; the greatest soly. and regularity of results occurred at 100°. Each curve is characteristic for the make of glass. The following glasses were studied: Cavalier used and new, Jena new and used, Pyrex, T, Maco and Resista; new Cavalier was less sol. than used; Jena glass was the least sol. Cu and Cr vessels were also used but gave inconsistent and irregular results. The greatest portion of the sol. compds. enter soln. during the first hr. of action; the addn. soln. after the first hr. was very small. FRANK MARESH

A simple device for the rapid determination of sugar in desugared cossettes. VL. STANĚK AND P. PAVLAS. *Listy Cukrovar.* **49**, 101–6(1930).—A small press, "kosmos," for yielding juice from desugared cossettes is described. Various degrees of pressure, methods of boiling and particles of raw materials have no effect upon the results. A well-mixed batch of desugared cossettes (0.5–0.75 kg.) is passed through the "kosmos." The first 50 cc. of juice is discarded, the next 100 cc. is digested with 0.75 g. of a powder contg. finely ground CaO 1 part and ordinary Pb acetate 25 parts. The mixt. is filtered and polarized. The sugar content is computed by multiplying the polarization value in a 200-mm. tube by 0.26, or it may be computed from tables. An analysis requires 8.5 min. FRANK MARESH

The isolation of choline from molasses. VL. STANĚK. *Listy Cukrovar.* **49**, 135–7 (1930).—Choline is pptd. in an alk. medium (by Reinecke's salts) in dilns. of 0.002% and in the presence of 20% sugar. Betaine is pptd. only in acid solns. Molasses was diluted with 5 vols. of luke-warm water, made alk. with Na_2CO_3, and permitted to stand. The clear soln. was decanted and treated with Reinecke's salts (0.5 part salt per 100 parts molasses). In a short period delicate crystals appeared. The mixt was left at a warm temp. for 2–3 days, washed by decantation and filtered. The residue while still moist was mixed with H_2O at 50°, treated alternately with $CuSO_4$ soln. and H_2SO_3 until SO_2 was evolved and the soln. yielded a blue filtrate. The soln. was boiled for several hrs., and the CuCNS filtered off. The clear filtrate was treated with an excess $Ba(OH)_2$, filtered, satd. with CO_2 and the final traces of Cu were removed with H_2S. After filtering, the soln. was evapd. to a small vol., acidified strongly with HCl, and evapd. to dryness *in vacuo*. The combined choline-Reinecke salt adsorbs some betaine in alk. soln. For sepg. choline-HCl from betaine-HCl, the dry mixt. was covered with abs. EtOH, and revapd. to dryness to remove the last traces of water. By

repeated extns. with abs. EtOH, choline-HCl crystd. as long colorless needles. The choline was identified as a $PtCl_4$ salt, by reactions with tannic acid, with I-KI soln. and with phosphotungstic acid. Full details for prepg. Reinecke's salt are given. Molasses contained 0.028–0.049% choline. FRANK MARESH

The electrical conductivity of molasses and sugar liquors. J. PELLER. *Listy Cukrovar.* **49**, 76–80(1930).—A special cond. cell permitting cond. measurements in molasses of high viscosity is described. The sucrose content and sp. resistance of the molasses are compared. The cond. of undiluted molasses is affected more by the water content than by the ash. The correlation of cond. and sp. gr. is invalid because of different viscosities with the same content of solids and compn. of nonsugars. During concn. processes, the resistivity of the molasses increases; crude liquors have a low resistance; refined liquors possess the highest. The presence of sugar crystals in molasses increases the resistivity of the liquid by decreasing the effective cross section of the conducting medium and by some unstudied undefined effects. F. M.

Determination of hydrogen-ion concentration by the Hellige comparator. J. GUILLAUME. *Bull. assoc. chim. sucr. dist* **47**, 450-4(1930).—A detailed review of the method of use is given. F. CAMPS-CAMPINS

Some data about calcium carbonate hydrate. V. V. YANOVSKII AND G. M. BUNICH. *Zhur. Sakharnoi Prom.* **4**, 265-73(1930).—If a soln. of sugar and CaO is carbonated with CO_2 to a thick mass, excess of CO_2 removed, the flask tightly stoppered and left at a temp. of about 10° for 20–30 hrs., the amorphous residue will crystallize and the polarization of the filtrate will be somewhat higher than that of the initial soln. of neutralized monosaccharate. Several expts. were performed and it was found: $CaCO_3 \cdot 6H_2O$ can be obtained by different methods at a temp. under 20°. The hydrate forms crystals of the monoclinic system with sp. gr. 1.808; it is sol. in monosaccharate, easily loses its water and changes into a modification of $CaCO_3$ with sp. gr. 2.6205 (probably Vaterit). Sucrose and glucose influence the form of crystallography of $CaCO_3$. Many irregularities in sugar manuf. are probably due to improperly conducted satn., which interferes with the conversion of sol. $CaCO_3$ into the insol. form. Gradual satn., increase of the temp. to 100° at the last period of carbonation with decreasing rate of speed, decrease of alky. to a min. and return of the filter-press cakes to diffusion juice will aid the filtration and quality of the juices. V. E. BAIKOW

The washing of diffusion cells. E. PŠENIČKA. *Listy Cukrovar.* **49**, 166–9(1930).—A washing device is described; it functions at a low pressure head and small vols. of water. It does not form channels and washes the inside wall of the diffusion cells. FRANK MARESH

The commercial production of glucose. A. E. WILLIAMS. *Ind. Chemist* **6**, 495–9 (1930).—After a brief presentation of the chemistry of the hydrolysis of starch and the influence of pressure upon the rate of hydrolysis, W. gives an account of the manuf. and uses of the com. products resulting from this hydrolysis. Two illustrations and a short list of references are included. E. G. R. ARDAGH

Effect of amino acids on rotation of glucose and fructose and its significance to determination of sucrose by double polarization methods. D. T. ENGLIS AND F. A. DYKINS. *Ind. Eng. Chem., Anal. Ed.* **3**, 17–21(1931).—The effect of alky. on the combination of glucose with glycine is extended with studies of the effect of temp. and different mol. relationships. The extent of combination was followed polarimetrically and by an iodometric detn. of uncombined glucose. The combination increases with increase in p_H. At 25° the glucose-glycine complex was almost completely reversed by acidification while at 35° some of the stable type of melanoidal combination was evident. Near 0° the extent of the reaction was very limited. Similar expts. with asparagine in place of glycine gave the same general effects although of different magnitudes. Fructose showed no optical changes in the presence of either glycine or asparagine with increasing p_H, which could not be attributed to alky. alone. The significance of the effect of p_H, of time of standing and of temp. on the detn. of sucrose in the presence of amino acids is discussed. H. W. LEAHY

Determination of glucose in presence of fructose and glycine by iodometric method. F. A. DYKINS AND D. T. ENGLIS. *Ind. Eng. Chem., Anal. Ed.* **3**, 21–3(1931); cf. preceding abstr.—A study is made of the effect of fructose and glycine upon the detn. of glucose by oxidation with alk. I soln. in the presence of NaOH, Na_2CO_3 and phosphate buffers. The rate of oxidation is so rapid that the extent of condensation of the glucose with glycine is negligible, and there is no tendency for low results due to this cause if the soln. is neutral at the beginning of analysis. The results are always higher than those due to glucose alone because of reduction of I by fructose and glycine. Even though the fructose-glycine complex is formed immediately it has little protective ac-

tion against the oxidizing agent. Of the various basic reagents used with I, Na_2HPO_4 had a no. of advantages and gave the most satisfactory results. H. W. LEAHY

Ionometer system of P. V. Golovin (GOLOVIN, PATER) **1.** Waste waters from sugar factories (MANUELLI, ANSELMI) **14.** Are waste waters from a potato-starch factory injurious to fish? ALLEN ROGERS

Action of pepsin on leather. V. S. SADIKOV AND E. BLINCHIK. *Zhur. Prikladnoi Khim.* **3**, 905–14(1930).—Pepsin has a decided action on leather and shortens the time required for tanning. V. KALICHEVSKY

Detection of the method of tanning used in mineral tanning with a small sample of leather. KARL KLANFER. *Mikrochemie* **3**, 34–7(1931).—*Detection of Cr.*—Shave off a piece of the leather (less than 1 mg.) and fuse its ash with a little Na_2O_2 in a micro porcelain crucible Treat the product with a few drops of 6 *N* H_2SO_4, and add 1–2 drops of 2% diphenylcarbazide soln. in alc. If Cr is present, an intense violet coloration will be obtained. *Detection of Fe.*—Treat the ash from a small sliver of leather with a drop of concd. HNO_3, evap. to dryness, ignite and fuse with a little $KHSO_4$. Dissolve the cold melt in dil. H_2SO_4, and test with a drop of KCNS soln. *Detection of Al.*—Fuse the ash from a little leather with $KHSO_4$, dissolve the melt in a few drops of hot water and test with alizarin or with morin. In the former case, transfer a drop of the soln. to a piece of dry test paper which has been impregnated with $K_4Fe(CN)_6$. This serves to hold back any Fe or Cr, but the Al passes through, forming a circular outer zone on the paper. Add to this a drop of satd. alizarin soln. in alc., and hold the paper over the mouth of an NH_4OH bottle. The violet-colored Al lake is formed. Sometimes, when considerable Al is present, the strawberry-red of Al alizarinate is noticeable but, by heating, this can be made to disappear and the desired violet shade obtained. To apply the morin test, take a drop of the soln. of the melt in a small pointed tube, add 2 drops of hot 2 *N* NaOH, centrifuge and treat the alk. soln. with a little AcOH and a drop of a satd. soln. of morin in MeOH A green fluorescence shows Al is present. W. T. H.

Technical preparation of glue and gelatin. D. GURIAN. *Kolloid-Z.* **54**, 106–12 (1931).—A review of German patents. A. FLEISCHER

Heat-coagulable protein from gelatin (SHEPPARD, *et al.*) 11A.

Tanning. D. L. LEVY. Brit. 335,252, June 21, 1929. See U. S. 1,742,514 (*C. A.* 24, 1247).

Tanning. J. R. GEIGY A.-G. Ger. 514,240, Aug. 6, 1925. Skins are partly tanned by means of H_2SiF_6 or its salts, the tanning being completed simultaneously or subsequently by means of vegetable, mineral or synthetic tanning agents, or sulfite cellulose lye, or mixts. of these. Examples are given.

Tanning skins and leather. MAXIME JOLY and LOUIS MAINGUENEAU. Fr. 692,347, Mar. 20, 1930. Skins and leather are tanned by various chem. solns. used separately or in combination such as sulfates of Cd, Co, Cu, Al, Fe, Ni, Zn and NH_4 vanadate.

Tanning sole leather. CHARLES KANNEL. U. S. 1,789,629, Jan. 20. Cleaned limed skins are treated for 16–24 hrs. in a bath to which K chromate 250, H_2BO_3 200, formic acid 180 and glycerol 50 g. are added for every 100 qt. of water in the bath.

Treating different portions of hides by separate finishing operations. W. B. CAMPBELL. Brit. 334,848, Feb. 25, 1929. For boot or shoe manuf. or other purposes, a hide, after tanning and prepn. to receive a surface finish, is cut into selected parts (according to the varying quality of the hide) for articles to be produced and these parts are then individually finished as required. To enable storage of the hides before finishing, there may be added about 2% of lactic acid to chrome tanning liquor, or the hides may be conditioned after a chrome bath by soaking in a soln. formed with NaCl, Na_2SO_4, glucose and glycerol. Alum-tanned hides may be similarly treated. Fat liquoring and other treatments are also described.

Leather dyeing composition. LYNN A. WATT (to Monsanto Chemical Works). U. S. 1,789,375, Jan. 20. *o*-Dichlorobenzene 30 g., spirit-sol. nigrosine 7.5 g. and "red oil" (oleic acid) 5 g. are mixed with sufficient denatured EtOH to make a total of 100 cc.

"Patent leather." ARTHUR S. HUBBARD (to Turner Tanning Machinery Co.). U. S. 1,789,550, Jan. 20. An app. is described with fused quartz Hg-vapor lamps for treating varnished hides or fabrics with ultra-violet rays and with app. for conditioning and humidifying the air in contact with the material.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

The rubber industry in 1930. S. A. BRAZIER. *Ind. Chemist* 7, No. 72, 9–12(1931). E. H.

Structure viscosity of rubber solutions. B. DOGADKIN AND D. PEWSNER. *Kolloid-Z.* 53, 239–45(1930).—The viscosities of pale crepe, smoked sheet and milled rubber solns. in C_6H_6 at 15°, 25° and 45° were measured at varying pressures. Deviations from the Hagen-Poiseuille law were checked. The results may be expressed by the Waele-Ostwald formula: $\eta = KP^{1-n}$. The exponent n of this equation may be used as a measure of structural peculiarities of different rubbers and it characterizes various changes in the aggregation of rubber. With increasing temp., n increases with diminution in viscosity. Milling, which represents colloid-chem. processes of disintegration, causes a large decrease in the structure viscosity exponent. A similar process occurs in the aging of rubber solns. ARTHUR FLEISCHER

Micromanipulations on latex in dark fields. E. A. HAUSER. *Kolloid-Z.* 53, 78–82 (1930).—New investigations have confirmed the previous results of Freundlich and H. (cf. *C. A.* 19, 2280). For latex from trees of different age, the thickness of the solid layer of the latex particle increases with the age of the tree. By coagulation of the latex, particles with noticeable elastic properties are obtained, in which the consistency of the inner and outer layers is not distinguishable. ARTHUR FLEISCHER

Determination of p_H of ammonia latex. J. MCGAVACK AND J. S. RUMBOLD. *Ind. Eng. Chem., Anal. Ed.* 3, 94–7(1931).—Details of expts. are given in which the p_H of latex was detd. at various NH_3 concns. by the use of indicators and with the glass electrode. The 2 curves thus obtained were comparable but not identical. The glass electrode method gives results which are reproducible and accurate up to p_H 9.5, and which are fairly accurate up to p_H 11.0. In more alk. solns. it is necessary to carefully calibrate each electrode. An ordinary galvanometer gave satisfactory results with potentials down to 1 millivolt, and the asymmetry of the glass was negligible. W. T. H.

The constitution of rubber. R. PUMMERER. *Kolloid-Z.* **53,** 75–8(1930).—A chem. method is needed to decide whether the rubber mol. is a system of closed isopentene rings or is a long chain mol. ARTHUR FLEISCHER

Solvent action in rubber. P. STAMBERGER AND C. M. BLOW. *Kolloid-Z.* **53,** 90–5(1930); cf. *C. A.* **23,** 4846.—Osmotic pressure detns. of rubber solns. in toluene at 25° checked the older results of Posnjak, though the rubber samples were from entirely different sources. The plot of $\log P$ against $\log c$ for the equation $P = P_0 c^K$ does not give a straight line, showing that K changes with the concn. There is no difference between the osmotic pressure of gels and solns. Different rubbers gave the same values of the osmotic pressure at like concns. The viscosity-pressure diagrams of petr. ether and benzene solns. of milled rubber were not very different, though optically they were quite different. The viscosity curves of solns. of dead-milled rubber, the same rubber with 15% of gas black dissolved at once and after 30 days, showed increasing viscosities in the above order. These solns. were thixotropic. ARTHUR FLEISCHER

The fusion curve of natural rubber. G. v. SUSICH. *Naturwissenschaften* **18,** 915–6 (1930).—Previously frozen raw rubber has a "m. p." at 35–8°. The crystal interferences in the x-ray diagram disappear at this temp. and the rubber becomes elastic. High stretching raises this m. p. A diagram is given of elongation *vs.* temp., in which the m.-p. curve is shown. Crystn. is characterized by the initial appearance of the (200) interference. For 1000% elongation the m. p. is between 80° and 90°.
B. J. C. VAN DER HOEVEN

Rubber preservatives. RUDOLF DITMAR. *Chem.-Ztg.* **54,** 994–6(1930). —A review, with particular reference to the many patented substances. C. C. DAVIS

Determination of alkalinity of reclaimed rubber. HENRY F. PALMER AND GEORGE W. MILLER. *Ind. Eng. Chem., Anal. Ed.* **3,** 45–8(1931). —A new method for detg. the relative alky. of reclaimed rubber is described, and compared with an earlier method already described (cf. *C. A.* **22,** 1058). The alkali is extd. by digestion of the reclaimed rubber in a mixt. of EtOH, C_6H_6 and water. The expts. show that the new method gives reliable results, which are approx. 4 times as precise as those of the previous method. This greater precision is a result of the elimination of much of the personal error, of extn. of a larger proportion of alkali, and of a closer end point in the titration. C. C. D.

Overflow during vulcanization of rubber and its results. F. KIRCHHOF. *Chem.-Ztg.* **54,** 906–8(1930). —A criticism of a paper by Ditmar and Preusse (cf. *C. A.* **24,** 5179–80) with certain new data on the expansion of rubber mixts. during vulcanization. These new data, in conjunction with the results of D. and P. and other investigators, lead to certain conclusions. (1) Raw rubber and rubber mixts. show in the temp. interval between room temp. and the temp. of vulcanization considerable evolution of heat. (2) The d. of raw rubber and rubber mixts. is, within narrow limits (2–3 decimals), dependent upon the time and temp. of mastication. (3) Upon storage the d. increases as a result of reaggregation. (4) Soft vulcanization in principle involves a contraction of vol., *i. e.*, an increase in d. Under normal conditions this increase is about 2.0% (calcd. on the unvulcanized mixts.). (5) Hard-rubber vulcanization likewise involves a contraction of vol., *i. e.*, increase in d., which may reach 6%. (6) The pressure used in vulcanizing increases the d., and this is of the same order of magnitude as the increase resulting from reaggregation. (7) Certain active fillers (heavy metal oxides and sulfides) when in large proportions have a similar contractive effect to small proportions of Se or considerable S. (8) These effects are probably attributable to capillary or affinity forces. (9) The overflow which takes place during vulcanization in a press is chiefly the result of purely mech. factors (compression) but is to some extent a result of heat expansion and vol. contraction. C. C. DAVIS

Synthetic materials [rubber] (Fr. pat. 691,901) **18.**

Annuaire technique de caoutchouc de la gutta-percha et des industries qui s'y rattachent. Paris: Cillard. 200 pp. Paper, F. 49. Reviewed in *J. Franklin Inst.* **210,** 121(1930).

HARPEN, N. H. VAN: **The Electrometric Determination of the Hydrogen-Ion Concentration on the Latex of Hevea Brasiliensis and Its Applicability to Technical Problems.** Medan: Varekamp & Co. 460 pp. Reviewed in *Rubber Age* **28,** 428(1931).

Rubber. THE ANODE RUBBER CO., LTD. Ger. 511,837, Feb. 23, 1927. Aq. disper-

sions of vulcanized or unvulcanized rubber, regenerated rubber, factice, etc., are obtained by adding a dispersion agent or protective colloid, *e. g.*, olein and NH_3, during the mech. working up of the rubber, etc., with alkali.

Rubber. FIRMA TOKYO GOMU KABUSHIKI KAISHA. Ger. 512,747, June 4, 1927. A rubber mixt. which floats in water and withstands mineral oil is prepd. by mixing alkali soap with the rubber from factice S and diphenylguanidine Inorg. filling material is omitted.

Rubber. ISIDOR TRAUBE. Ger. 512,599, July 13, 1926. Latex or latex concentrations are coagulated by addn. of gall or gall-contg. material Org solvents such as C_6H_6, $CHCl_3$, oil of turpentine, etc., may be added before or during the addn. of gall.

Rubber. DUNLOP RUBBER CO., LTD., and THE ANODE RUBBER CO., LTD. Fr. 691,556, Mar. 7, 1930. The alkalinity of rubber latex dispersions, which have been preserved by a base such as NH_3, is reduced by a treatment with absorbent agents belonging to the class which contain SiO_2-gel, colloidal Al_2O_3 and active C.

Rubber. SHERARD O. COWPER-COLES. Fr. 691,912, Nov. 15, 1927. Rubber is prepd. by electrolytic deposition from latex on a suitable base as anode in an intermittent manner, either by passing the current at intervals through the latex or by removing at intervals from the action of the current the surface on which the rubber is deposited. NH_4OAc may be added to the latex to increase the cond. Powd. metal may be deposited at the same time as the rubber

Rubber latex. JACQUES AUMARÉCHAL and GEORGES ROBRIEUX. Fr. 692,076, April 16, 1929. The viscosity of latex is increased by submitting it to a cooking and then pptg. at low temp. the vegetable gelatinous materials without coagulating the globules of rubber by chem. salts having a sp. action on these materials. An example is given using $Pb(OAc)_2$ as pptg. agent. Fr. 692,077 describes the removal of preservers from latex by converting them into accelerators of vulcanization, by the introduction of chem compds. capable of uniting with them without coagulating the rubber. Thus, if NH_3 or aromatic amines are used as preservers, aldehydes or CS_2 are added to convert them to accelerators Fr. 692,078, May 2, 1929, describes an app. for concg. latex.

Rubber deposition by electrophoresis. SIEMENS & HALSKE A.-G. Brit. 334,871, Jan. 17, 1929. The process for electrophoretic deposition of rubber by a. c. described in Brit. 307,747 (*C. A.* **24**, 265) is modified by the introduction of electrolytes (such as $MgCl_2$, NH_4Cl or HOAc) into the latex itself or by satg. the porous molds surrounding the electrodes with electrolytes (instead of or in addn. to the introduction of electrolytes into the electrode spaces). A detailed example is given of the use of electrodes covered with plaster of Paris and satd. with a 20% $CaCl_2$ soln.

Rubber compositions. THE BARRETT CO. Fr. 691,828, Mar. 12, 1930. A softening and dispersing agent for making rubber compositions consists of a tar oil free from cryst. substances at 25°, having a sp. wt. not less than 1.06 at 38° and boiling above 200°. Examples and the properties of the resulting compns. are given.

Preserving aldehyde-amines in rubber batches. SHERMAN I. STRICKHOUSER (to The Dominion Rubber Co., Ltd.). Can. 308,123, Jan. 27, 1931. The deterioration of aldehyde-amine condensation products in rubber batches is retarded by mixing the products with rubber in the presence of hydroquinone.

Antioxidant for rubber. ALBERT M. CLIFFORD (to Goodyear Tire and Rubber Co.). Can. 308,362, Feb. 3, 1931. Rubber is preserved by vulcanizing in the presence of an arylamine deriv. of diaminotriphenylmethane.

Age-resisting rubber. HAROLD W. ELLEY (to E. I. du Pont de Nemours & Co). Can. 308,347, Feb. 3, 1931. Rubber is made resistant to aging by incorporating the reaction product of α-naphthol and an amine in the mixt. before vulcanization. Cf. *C. A.* **24**, 3925.

Retarding the aging or deterioration of rubber. THE NAUGATUCK CHEMICAL COMPANY. Ger. 512,659, Feb. 8, 1930. The process consists of treating rubber with diaminodiphenylmethane or a CH_2O condensation product. Tables showing the effect of these addns on rubber after intervals of artificial aging are given.

Retarding deterioration of rubber. WM. S. CALCOTT and WM. A. DOUGLASS (to E. I. du Pont de Nemours & Co.) U. S. 1,789,696, Jan. 20. There is incorporated with the rubber a small proportion (suitably about 5%) of a reaction product of C_2H_2 with an amino compd such as aniline, benzidine or *p*-aminophenol.

Working up scrap rubberized fabric. WARREN BROTHERS CO. Ger. 511,087, Jan. 21, 1926. Scrap rubberized fabric, *e. g.*, automobile tires, is comminuted and then mixed at a raised temp. with mineral fillers and bituminous material. The compn. so obtained is suitable for *road-making, roofing,* etc Details are given.

Hollow rubber articles. AYRTON SAUNDERS & CO., LTD., and F. TWELLS. Brit. 335,267, June 4, 1929. Articles formed of rubber over a foundation layer such as canvas are provided with a lining of different rubber compn. from the outer rubber facing and contg. about 5% carbon black so that it has a lower capacity for absorbing water.

Material for gas receptacles. A. GOLDBERG. Brit. 335,145, Feb. 5, 1929. A material suitable for making gas receptacles such as those used in respiration expts. comprises 2 rubber sheets with an intervening sheet of metal foil, either stuck or vulcanized together.

Artificial rubber. I. G. FARBENIND. A.-G. (Walter Bock and Eduard Tschunkur, inventors). Ger. 511,145, Jan. 15, 1927. See Brit. 283,840,(*C. A.* **22**, 4274).

Coating compositions, etc., from synthetic rubber. I. G. FARBENIND. A.-G. Brit. 334,961, March 15, 1929. Polymerization products of diolefins produced as described in Brit. 333.872 (*C. A.* **25**, 710) are hardened by any suitable method such as by the action of air or O in the presence of oxidation catalysts, treatment with $AlCl_3$ or action of S or S_2Cl_2 with or without vulcanization accelerators. The hardened material may be used for *lacquer coatings, artificial threads, linoleum manuf.*, etc., with or without admixt. with other materials such as cellulose esters, natural or artificial resins, solvents, softening agents, waxes and drying oils. Numerous details and examples are given.

Polymerizing butadiene hydrocarbons. HANS LECHER and ALBERT KOCH (to I. G. Farbenind. A.-G.). U. S. 1,789,873, Jan. 20. An emulsion such as may be formed of isoprene and Na oleate soln. is homogenized before polymerization.

Rubber for dental purposes. CHRISTE JOANNIDES. Ger. 513,316, June 13, 1923. See Brit. 224,032 (*C. A.* **19**, 1210).

Hollow articles of vulcanized rubber. I. G. FARBENIND. A.-G. (Wilfried Genth, inventor). Ger. 511,056, Mar. 22, 1928. See U. S. 1,765,666 (*C. A.* **24**, 4186).

Vulcanizing rubber objects. ERNST WLCECK. Ger. 513,429, Jan. 16, 1927. Addn. to 452,466. According to Ger. 452,466, prepd. sheets or other rubber articles are vulcanized in the cold by alternate immersion in a 4–10% aq. SO_2 soln. and a satd. aq. soln. of H_2S. The treatment may be repeated as required. This method is now modified by adding to the rubber compn. a compd which will liberate S when the article is immersed in a suitable bath. Thus, CaS and other sulfides may be added to the compn., and the article immersed in an aq. soln. of SO_2.

Vulcanized products. JOSEPH C. PATRICK and NATHAN M. MNOOKIN. Fr. 692,235, Mar. 18, 1930. Rubber is mixed with a plastic material formed of a polysulfide and olefin (see Fr. 656,114, *C. A.* **23**, 4030) and vulcanized by heat. The plastic material and free S are chosen so that the content of S in the product is at least 50%.

Vulcanizing core. DUNLOP RUBBER CO., LTD., and T. NORCROSS. Brit. 335,304, July 12, 1929.

Rubber vulcanization (air and steam supply and regulating system). MELVON A. MARQUETTE (to Fisk Rubber Co.). U. S. 1,790,011, Jan. 27. Various details of procedure are described.

Vulcanizing rubber. FREDERICK W. FARR. Fr. 692,172, Feb. 13, 1930. Rubber or like compns. are vulcanized in the cold by causing dild. S_2Cl_2 to pass through the whole thickness of the rubber, which is cut up into granules or little pieces to allow the penetration of the vulcanizing fluid, or fibrous material is agglomerated with the rubber to allow penetration of the fluid. Cf. *C. A.* **24**, 3400.

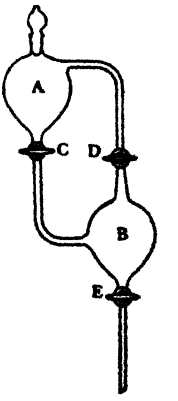
Vulcanizing rubber. JOSEPH C. PATRICK. Fr. 691,743, Mar. 11, 1930. Rubber is vulcanized by heating it with a plastic compn. made by the reaction of an alkali polysulfide on a dihalogen olefin and contg. 75% or more of S. Compds. such as ZnO, $(CH_2)_6N_4$, Pb oleate and lampblack may also be added.

Vulcanizing rubber. I. G. FARBENIND. A.-G. Fr. 691,821, Mar. 12, 1930. The vulcanization of natural or artificial rubber is accelerated by adding to the mass to be vulcanized the products of the action of NH_3 on unsatd. aldehydes such as crotonic aldehyde, acrolein, methylpropylacrolein and ethylpropylacrolein.

Vulcanizing rubber, etc. SOCIETÀ ITALIANA PIRELLI. Fr. 691,456, Mar. 7, 1920. Rubber, ebonite, etc., are vulcanized by a preliminary heat treatment in molds and a subsequent complete vulcanization of the objects immersed in water in a suitable autoclave, carried to the vulcanization temp. and kept at a pressure greater than the characteristic pressure of satd. steam at that temp.

CHEMICAL ABSTRACTS

Vol. 25. APRIL 10, 1931 No. 7



1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A new high-efficiency glass condenser. PAUL R. CRANDALL. *J. Lab. Clin. Med.* **16**, 89–91(1930).—A glass condenser is described which may be used in an all-glass distg. system. Approx. 2 l. of distd. H_2O per hr. may be produced. E. R. MAIN

A simplified apparatus for the extraction of liquids. R. B. FORSTER. *Chemistry and Industry* **50**, 44(1931).—The app. was designed for extg. H_2O solns. with lighter solvents. A tube from the closed bottom of the cylindrical extractor connects with the boiling flask. A by-pass from this tube enters the extractor about half-way up, serving as a passage for the vapor to the condenser on top and as a return for the solvent to the boiling flask. The soln. to be extd. is placed in the lower half of the extractor, the condensate falls into a thistle tube which delivers it at the bottom of the soln., through which it rises and overflows to the boiling flask, its rise being impeded by baffles attached to the stem of the thistle tube. Cf. *C. A.* **20**, 3817. J. H. MOORE

A separatory funnel for washing heavy volatile liquids. HAROLD S. KING. *Proc. Trans. Nova Scotian Inst. Sci.* **17**, 240–1(1930).—Two separatory funnels are sealed together in such a way (see fig.) that a heavy liquid in the first can be sepd. from a supernatant liquid and delivered to the 2nd funnel without contact with the outside atm. After removal of the supernatant liquid, the heavy liquid can be returned to the first funnel for rewashing. RACHEL BROWN

An improved pipet manipulator. D. C. B. DUFF. *J. Lab. Clin. Med.* **15**, 1027–8(1930). E. R. MAIN

Improved slow-combustion pipet for gas analysis. H. R. AMBLER. *J. Sci. Instruments* **8**, 18–9(1931).—O is led into the gas through a capillary side tube entering near the bottom of the Hg in the pipet, thus preventing back-diffusion of the gas. Analyses by absorption in liquids may be made by bubbling the gas through the side tube. J. H. MOORE

Automatic gas-analysis apparatus based on the thermal conductivity of gases, and its use in industry. PAUL JARRIER. *Chaleur et ind.* **11**, 181–5(1930).—A table of densities, viscosities and thermal conductivities of air, N_2, O_2, CO, CO_2, water vapor, H_2, C_2H_2, CH_4, lighting gas, NH_3 and SO_2 is given. The Ranarex app. is described; it gives good results. The principle of the Dommer "Unograph" is illustrated and described. The Siemens elec. CO_2 indicator is described. The elec. measurement of the thermal conductivities of mixts. of gases and its applications are discussed. S. L. B. ETHERTON

A thermal method for the rapid measurement of carbon monoxide. GERHARD STAMPE. *Messtech.* **6**, 267–70(1930).—The Drager app. is described. It depends on measuring the temp. of the gas on entering and leaving a catalyzing chamber in which it is oxidized to CO_2. The theory is discussed, with 7 references. Cf. *C. A.* **24**, 5897. J. H. MOORE

Determination of humidity. G. ALIVERTI. *Nuovo cimento* **6**, cxvii–cxxiii(1929).—A discussion of the use of various types of hygrometer. B. C. A.

A convenient hydrometer for determining the specific gravity of heavy liquids. A. C. TESTER. *Science* **73**, 130–1(1931).—The app. was devised for liquids of sp. gr. between 2.0 and 5.0 for use in *the sepn. of minerals.* Only 5 cc. of the liquid is necessary. The sp. gr. of solids may also be detd. J. H. MOORE

An improved portable p_H apparatus. ARAO ITANO. *Ber. Ohara Inst. landw. Forsch.* (Japan) **4**, 471–4(1930); cf. *C. A.* **23**, 3602.—The app. previously described has been changed to make one instrument serve as both galvanometer and millivoltmeter; it is manipulated by means of a newly constructed double-throw switch. The

wiring diagram and a photograph of the app. are shown. The instrument measures the e. m. f. of the cell: quinhydrone, standard p_H soln. | saturated KCl | sample, quinhydrone. N. A. LANGE

Deposition filter process. ARMIN BLUMENTHAL. *Pharm. Presse wiss-prakt. Heft* 1930, 165–6.—Several illustrations are given of an improved type of filter for large operations; it has compartments filled with frames carrying wire gauze on which the filter mass (asbestos or other suitable material) is flooded and deposited in thin paper-like layers. The various operations are carried out under pressure and suction. W. O. E.

The Schacht-Wheel drier. VON BEZOLD. *Chem. App.* **17**, 217–8(1930).—The drier contains a series of cylinders vertically arranged, over which the material is passed and drops to the wheel below. Hot air is blown upward. The drier will not operate with materials which are larger than hazel-nut size or which are sticky or liable to cause explosion. M. C. ROGERS

The sucking off and precipitation of dust and vapors. A. VOGT. *Chem. App.* **17**, 209–10(1930).—The app. is arranged so that gases contg. dust are put in contact with a stream of water and passed into a settling tank. The sludge settles and the clear liquor overflows to a launder and is pumped again to the mixing chamber. The settled sludge can be pumped off through a discharge opening in the bottom of the settler. M. C. ROGERS

An instrument to measure soil consolidation. CORNELIUS DAVIES. *J. South-Eastern Agr. Coll., Wye, Kent*, No. 27, 225–7(1930).—An instrument for measuring the compactness of soils consists of 2 telescopic tubes within which is a supported spring balance so arranged that a push on the handle of the appliance extends the spring, a scale calibrated in 0.5 lb.; a max. reading indicator; and a set of steel probes of different lengths and diams. K. D. JACOB

Illumination of the half-shadow polarimeter with a mercury-quartz lamp. HANS N. NAUMANN. *Biochem. Z.* 229, 269–70(1930).—The use of the Hg-quartz lamp as a source of illumination increases the accuracy of the polarimeter 2–3 times; this is of great significance in the study of weakly rotating substances. S. MORGULIS

Theory of optical pyrometers and description of some new improvements. S. HELD *Chaleur et ind.* **11**, 403–10, 473–80(1930). S. L. B. ETHERTON

Leonard Hill acetone-methylene blue actinometer. T. W. B. OSBORN AND A. D STAMMERS. *Brit. J. Actinotherapy* 5, 68–9(1930).—Exclusion of air is essential for securing reproducible results. B. C. A.

An air-thermostat for corrosion research. U. R. EVANS. *Chemistry and Industry* **50**, 66–7(1931).—A uniform temp. is maintained by forced circulation of air from the chamber through channels between the double walls and back to the chamber. The elec. heating is controlled by an adjustable contact thermometer. J. H. MOORE

Photoelectric cell has definite place in color measurement (SCOTT) **25.** Electrometric measurement of very low pressures by means of ionization currents; the space charge manometer (MOLTHAN) **2.** Apparatus for determining the tendency of coal and other materials for spontaneous combustion (KREULEN) **21.**

DUBSKÝ, J. V.: **Selbstätige Filtrationsapparate.** Leipzig: Georg Thieme. 64 pp. M. 3. Reviewed in *Chem. News* **142**, 110(1931).

RABALD, ERICH: **Werkstoffe. Physikalische Eigenschaften und Korrosion.** Band I. **Allgemeiner Teil. Metallische Werkstoffe. Band II. Nichtmetallische Werkstoffe.** Leipzig-Reudnitz: Verlag von Otto Spamer. Stitched, M. 128; bound, M 135.

Gas filters. RENÉ LAHAUSSOIS. Fr. 693,035, Mar. 29, 1930. Pilous surfaces are obtained for gas filters with filaments submitted to a treatment such as the action of an electrostatic field so that they become stuck automatically at one end to an adhesive previously applied to the filtering surfaces.

Rotary screen and filter apparatus for reclaiming solid particles from gases. FRANK J. MCDEVITT. U. S. 1,791,102, Feb. 3. Structural features.

Centrifugal dust separators. SOC. HENRY SIMON, LTD., and GEORGE WATTS. Fr. 693,823, April 12, 1930.

Combined hydrometer, liquid casing and suction bulb. J. H. COLLIS. Brit. 335,698, Aug. 29, 1929.

Humidistat. EDWARD A. PORTER. U. S. 1,791,375, Feb. 3.

Calibrated viscometer. RICHARD VON DALLWITZ-WEGNER. Ger. 515,259, Jan. 19, 1926.

Hydrometer syringe for indicating specific gravity of liquids. ELLIS H. BRIDGE (to Electric Storage Battery Co.). U. S. 1,790,696, Feb. 3. Structural details.

Apparatus for the agitation and sedimentation of liquids and solids in suspension. THE DORR CO. Fr. 692,797, Mar. 26, 1930.

Apparatus for delivering liquids in measured quantities. WERNER HANDELSGES. Ger. 515,279, June 4, 1927.

Apparatus for evaporating and concentrating liquids by passing them through a heated centrifuge. MARTIN J. KERMER. U. S. 1,791,317, Feb. 3. Structural features.

Apparatus for effecting hydrogenations and other catalytic reactions between gases and liquids. RING GES. CHEM. UNTERNEHMUNGEN M. B. H. Ger. 515,447, Jan. 25, 1922.

Apparatus for treating gases with atomized liquids. STELLAWERK A.-G. VORM. WILISCH & CO. Ger. 514,413, Apr. 3, 1930. Addn. to 512,128 (*C. A.* **25**, 850).

Apparatus for regulating and indicating the density of mixed gases. SMOOT ENGINEERING CORP. Ger. 515,257, Jan. 29, 1928. See U. S. 1,682,689 (*C. A.* **22**, 3809).

Gas washing apparatus. H. A. BRASSERT (to H. A. Brassert & Co., Ltd.). Brit. 335,648, July 6, 1929. Various structural details are described of an app. comprising alternate rows of oppositely rotating or fixed and rotating bars grouped around an axis and fixed nozzles spraying the bars in an outward direction. Cf. *C. A.* **24**, 1254.

Apparatus with shields for reducing radiation effects in gas temperature determinations. ROBERT E. WILSON. U. S. 1,791,020, Feb. 3. Structural features.

Surface condenser suitable for condensing steam. CHARLES A. PARSONS and FREDERICK ARKLESS (Arkless to Parsons). U. S. 1,790,834, Feb. 3.

Evaporator calandria, etc. OSCAR H. WURSTER. U. S. 1,791,296, Feb. 3. Various details are described of an evaporator suitable for evapn. of crude glycerol.

Shaft drier, with grinding or comminuting means. BERNHARD SÄGEBARTH. Ger. 515,443, Oct. 21, 1927.

Centrifugal apparatus for dewatering linters, wood cellulose, etc. GEBR. BELLMER MASCHINENFABRIK. Ger. 515,463, Nov. 22, 1929. Addn. to 496,059 (*C. A.* **24**, 3139).

Röntgen-ray tube. C. H. F. MÜLLER A.-G. Brit. 335,510, Aug. 27, 1929. Structural and elec. features.

Cathodes for electron tubes. HERMANN LOOSLI. Ger. 515,095, Jan. 25, 1924. Cathodes, comprising an alk. earth oxide on a core of difficultly fusible metal, are prepd. by dipping the core into molten alk. earth metal, which is heated *in vacuo* or in an inert atm., and then oxidizing the metal coating on the core. Alternatively, the core may be embedded in a powd. mass of alk. earth metal which is heated *in vacuo* or in an inert atm.

Electric discharge tubes. J. E. LILIENFELD. Brit. 335,537, Oct. 3, 1928. Various details of manuf. are given of tubes which may be used for the production of Röntgen rays and which may have a cathode of W or Ta pointed by etching and activated by Cs evapd. in an adjacent tube.

Photoelectric cell. N. V. PHILIPS' GLOEILAMPENFABRIEKEN. Fr. 693,043, Mar. 29, 1930. A photoelec. cell contains a photoactive substance such as Cs spread on an intermediate layer contg. a chem. compd. and particles conducting electricity. The Cs is produced in the cell or in a chamber communicating with it by heating a mixt. contg. a compd. of Cs such as Cs chromate and a reducing agent such as Zr. The mixt. also contains a chem. compd. which during the heating is volatilized or reacts with the reducing agent present to form the intermediate layer. Cf. *C. A.* **24**, 2336.

Muffle furnace for calcining "chemicals," pigments or other pulverulent materials. R. KRAUSSE. Brit. 335,659, July 11, 1929. A muffle or retort extends through a furnace fired by burners and is suspended by blade springs so that it may be continuously reciprocated to convey the charge gradually from the inlet to the outlet end. Various details of construction are described. Cf. *C. A.* **24**, 3406.

Apparatus for controlling furnace combustion in accord with furnace boiler pressure variations. CHARLES M. TERRY (to A. W. Cash Co.). U. S. 1,790,685, Feb. 3.

Retort for stoker furnaces. WM. F. RIEGER (to Stoker-Matic Corp.). U. S. 1,790,840, Feb. 3.

Smoke inspection apparatus for boiler furnaces. ROBERT H. WAGER. Ger. 515,258, Feb. 24, 1929. Corresponds to Brit. 327,812.

Roofs for industrial furnaces. MAURICE GILBERT. Fr. 693,588, April 9, 1930.

Suspended roofs for furnaces. SOC. ANON. DES FOYERS AUTOMATIQUES. Fr. 692,542, Mar. 21, 1930.

Closures for annealing or melting furnaces. AKT.-GES. BROWN, BOVERI & CIE. Fr. 693,214, April 3, 1930.

Feeding device for crude lignite trough-grate furnace. FRÄNKEL & VIEBAHN. Ger. 515,403, Dec. 8, 1928.

Tuyère for underfeed stokers. ROBERT A. FORESMAN and DONALD J. MOSSHART (to Westinghouse Elec. and Mfg. Co.). U. S. 1,791,269, Feb. 3.

Step-grate. JOSEF MARTIN. Ger. 515,135 and 515,136, Dec. 15, 1926.

Device for separating dust from gases from rotary kilns, etc. EISEN- UND STAHLWERK HOESCH A.-G. Ger. 515,188, June 6, 1929.

Tilting plant for rotary drum ovens, etc. GEWERKSCHAFT EISENHÜTTE WESTFALIA. Ger. 515,041, Jan. 10, 1929.

Stamping device for use with rotary tube ovens. GEWERKSCHAFT EISENHÜTTE WESTFALIA. Ger. 515,392, Nov. 24, 1929.

Fan for increasing the draft in annular kilns and for cooling the discharge chamber. GUSTAV SCHRÖDER. Ger. 514,386, May 4, 1930.

Recording analyzer for industrial chemical control, more particularly of the purification of boiler-feed water. M. REIGNIER. Belg. 370,021, June 30, 1930. A wheel, operated by a drum which is released at regular intervals, carries 4 hinged beakers. In position 1 the beaker is filled with the sample to be analyzed; in position 2 the titration is carried out and recorded; in position 3 the beaker is emptied, and at 4 it is righted again. On the wheel are mounted spurs which open the cocks for the addn of the 3 reagents. A photoelec. cell opens the cock of the buret and closes it again when the phenolphthalein is decolorized.

Oil-feeding and -regulating device for oil burners. WM. R. RAY (to Ray Burner Co.). U. S. 1,791,012, Feb. 3. An automatic device is provided for varying the pressure on the oil in accordance with the temp. of the surrounding atm.

Gas burner. ALFRED J. REEDY (to A-B Stove Co.). U. S. 1,791,247, Feb. 3.

Gas burner. HARRY E. KERR (to Barber Gas Burner Co.). U. S. 1,791,360, Feb. 3.

Bunsen burners. LOUIS MARTIN. Fr. 693,535, April 8, 1930. Constructional details.

Heat-exchange device suitable for heating or cooling liquids. HERBERT V. DALGLIESH (to Research & Development Corp.). U. S. 1,791,483, Feb. 3. Structural features.

Heat-exchange apparatus suitable for use as a condenser, etc. STANLEY BROWN (to Griscom-Russell Co.). U. S. 1,790,897, Feb. 3. Structural features.

Die-casting machine. A C SPARK PLUG CO. Ger. 515,140, April 19, 1929. Corresponds to Brit. 332,277.

Centrifugal casting machine for making hollow bodies in horizontal molds. AURELIO POSSENTI and CARLO SCORZA. Ger. 515,139, Aug. 14, 1929.

Suction box for felted-sheet-making machines. OSTILIO SEVERINI (to Società Invenzioni Brevetti Anonima-Torino). U. S. 1,791,065, Feb. 3. Structural features.

Apparatus for continuous preparation of emulsions. RUDOLF AUERBACH. U. S. 1,790,967, Feb. 3. Structural features.

Apparatus for sterilizing rags, etc., with hot air and steam. HEINRICH HELI Ger. 515,405, Nov. 2, 1927.

Acetylene generator. DAYTON H. DANLEY. U. S. 1,791,194, Feb. 3. Structural features.

Acetylene generator, with counter-pressure chamber. I. G. FARBENIND. A.-G Ger. 514,437, Oct. 8, 1929.

Rubberized conveyor belts. R. S. CARTER (to Goodyear Tire & Rubber Co.) Brit. 335,475, April 16, 1929. The conveying surface is free from rubber so that it has a low coeff. of friction, while the driving surface is rubberized, and the belt may be formed of layers of fabric, some rubberized and some formed without rubber.

Photographic temperature-recording apparatus (suitable for use in ships' holds). OCEAN STEAM SHIP CO., LTD., and R. H. THORNTON. Brit. 335,644, July 6, 1929. Numerous structural details are described.

Thermostatic device. E. L. FONSECA (to Wilcolator Co.). Brit. 335,819, Nov 27, 1928. Structural and mech. details.

Thermostatic device suitable for control of electric circuits. HAROLD D. EATON (to Bastian-Morley Co.). U. S. 1,791,477, Feb. 3. Structural features.

Thermostatic electric switch. WM. A. RANKIN (to Robeson-Rochester Corp.). U. S. 1,791,225, Feb. 3. Structural features.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

The life work of M. W. Beijerinck. JAN SMITH. *Chem. Weekblad* **28**, 94–7 (1931).—A memorial address. G. G.

The scientific career of Henry Louis Le Chatelier. RALPH OESPER. *J. Chem. Education* **8**, 442–61(1931). E. H.

Charles Edward Coates. W. L. OWEN. *Ind. Eng. Chem.* **23**, 339–40(1931).—Biography with portrait. G. G.

Reminiscences of Gibbs by a student and colleague. EDWIN B. WILSON. *Sci. Monthly* **1931**, 211–27. E. H.

Wilhelm Hofmeister. A. H. LARSON. *Plant Physiology* **5**, 613–6(1930).—A biographical sketch accompanied by one plate WALTER THOMAS

Paul Julius. A. LÜTTRINGHAUS. *Z. angew. Chem.* **44**, 109–12(1931).—Obituary with portrait. E. H.

Håkan Sandqvist. ANON. *Svensk Farm. Tid.* **34**, 633–4.—Obituary with portrait. A. R. R.

C. Willgerodt. O. HINSBERG. *Chem.-Ztg.* **55**, 85(1931).—Obituary. E. H.

Nobel prizes in chemistry and physics for 1930: H. Fischer and C. V. Raman. ANON. *Svensk Kem. Tid.* **42**, 293–300(1930).—The accomplishments of these two scientists and their portraits are given. A. R. R.

Unrecognized and unknown facts about the origin of the combustion theory of Lavoisier. MAX SPETER. *Chem. Weekblad* **28**, 79–82(1931); cf. *C. A.* **20**, 1922(German).—The influence of Guyton de Morveau and Mitouart on Lavoisier is described. E. SCHOTTE

Changing attitudes in the history of chemistry. J. N. SWAN. *J. Chem. Education* 8, 510–4(1931). E. H.

An analysis of the college entrance examination board examinations in elementary chemistry for 1921 to 1928. JACOB W. BOORSTEIN. *Science Education* **15**, No. 2, 91–100(1931). E. H.

Questionnaire study of chemistry finances in South Dakota. RALPH DUNBAR AND J. ROBLEY LANE. *J. Chem. Education* **8**, 565–7(1931). E. H.

An administrative study on the teaching of chemistry in the secondary schools of South Carolina. G. G. NAUDAIN. *J. Chem. Education* **8**, 559–64(1931). E. H.

Dispensing laboratory solutions. CHARLES F. ECKELS. *J. Chem. Education* **8**, 543–5(1931). E. H.

Fertilizer from the air. A project for chemistry students at the secondary-schools level. HOWARD R. WILLIAMS. *J. Chem. Education* **8**, 462–70(1931). E. H.

An experiment on refractive index for the course in physical chemistry. CREIG S. HOYT. *J. Chem. Education* **8**, 537–8(1931). E. H.

Ashes and the remains of fuel found by the excavation of ruins of a seventeenth-century glass factory near the Keizergracht at Amsterdam. D. J. W. KREULEN. *Chem. Weekblad* **28**, 97–102(1931).—The fuel used in this glass factory was a high-volatile coal of English origin. G. G.

Geochemical distribution laws and cosmic frequencies of the elements. V. M. GOLDSCHMIDT. *Naturwissenschaften* **18**, 999–1013(1930); cf. *C. A.* **24**, 1259.—An elaborate review of the distribution of elements in the different spheres of the earth and in stellar bodies. It is concluded that the manner of distribution of the elements is detd. by properties of their electron shell; the frequency of occurrence of each type of atom, however, is detd. by properties of the nucleus. This frequency of occurrence is apparently the same in all parts of the cosmos. B. J. C. VAN DER HOEVEN

Changeable mass and the second law. S. MOHOROVIČIĆ. *Arhiv. Hem. Farm.* **4**, 169–74(174–5 German)(1930).—Mathematical. J. KUČERA

The calculation of chemical, electrical and gas-mechanical transformations of matter, energy and form by space energetics. RICHARD VON DALLWITZ-WEGNER. *Z. Elektrochem.* **37**, 25–33(1931).—On the basis of space energetics the equations derived for cohesion pressure, the processes in the Daniell cell, the mechanism of the galvanic cell, contact and thermal electricity, gas laws, efficiency and entropy are discussed. H. STOERTZ

Immersion liquids for determining refractivity of solid substances by the embedding method. A. MAYRHOFER. *Mikrochemie* **3**, 52–71(1931).—Purpose. To establish a

standard series of immersion mixts. of a few liquids which could replace the numerous embedding fluids that have been proposed in the literature. The mixts.—water-glycerol, cineole-paraffin oil, paraffin oil-α-bromonaphthalene, α-bromonaphthalene-CH_2I_2—are considered standard mixts. of the first line. The following mixts. have high n and by diln. with mixts. of lower n often serve for direct refractometric testing: paraffin oil-$CHBr_3$, $CHBr_3$-α-bromonaphthalene, $CHBr_3$-CH_2I_2. The percentage compns. of the mixts. studied were detd. by careful measurement of the ingredients in microburets. The regularities with respect to the refraction corresponding to the mixt. rule, the effect of keeping the mixts. for some time and the effects of temp. were studied. W. T. HALL

Electrometric measurement of very low pressures by means of ionization currents: the space charge manometer. WILHELM MOLTHAN. *Z. tech. Physik* **11**, 522–9(1930).—By the use of an electrometer method the sensitivity of pressure measurement by ionization can be raised from 10^{-7} mm. Hg to as low as 10^{-10} mm. Hg. A measuring tube with 4 electrodes is used in a circuit with electrometer and 2 triodes; calibration method and details are given. B. J. C. VAN DER HOEVEN

The development and present state of our knowledge of the natural system of elements (centenary of Lothar Meyer's birthday). F. PANETH. *Naturwissenschaften* 18, 964–76(1930).—A review. B. J. C. VAN DER HOEVEN

The ozone of the upper atmosphere. CH. FABRY. *Scientia* **49**, 11–22(1931). - This is a summary of the evidence relating to the presence and manner of distribution of ozone in the atm. The evidence is derived principally from the absorption spectra of the sun and stars. If the ozone in the atm. were uniformly distributed its concn. would be 60 mg. per 100 kg. of air. Actually, at the earth's surface, air contains about 3 mg. of ozone per 100 kg. Most of the ozone is distributed in the upper regions of the atm. at altitudes which are variable, and which are estd. to be from 20 to 50 kilometers. If the atm. ozone were segregated it would form a layer about 3 mm. thick at atm. pressure. The thickness of this layer, however, varies between extreme limits of 2 and 4 mm. due to seasonal and irregular causes. The origin of atm. ozone is uncertain. Speculations are advanced regarding the relation of atm. ozone to certain phenomena of the upper atm. It is estd. that atm. ozone is responsible for the absorption of about 4% of the sun's energy that is incident on the upper atm. R. H. L.

Unit of atomic weight. F. W. ASTON. *Nature* **126**, 953(1930).—None of the suggestions so far advanced for a new unit of at. wt. is free from objections. While extreme accuracy is not vital for chemists, physicists now need an accuracy of 1 in 10,000. GREGG M. EVANS

Magnetic rotary power of hydrocarbons in the gaseous state. R. DE MALLEMANN AND P. GABIANO. *Compt. rend.* **191**, 1319–20(1930).—By using $\lambda = 578$ mμ, the Verdet const., sp. and mol. rotations for methane, ethane, propane, butane, isopentane and hexane were detd. for the gaseous state and, for the 3 latter, in the liquid state. The dispersion ratios for $\lambda = 546$ mμ and $\lambda = 436$ mμ are 1.125 and 1.84 for all the hydrocarbons. F. W. LAIRD

The magnetic rotatory polarization of fused organic substances. CONSTANTIN SALCEANU. *Compt. rend.* **191**, 1316–8(1930); cf. *C. A.* **24**, 3682.—The variation with temp. of the magnetic rotatory power and magnetic double refraction of fused naphthalene and β-methylnaphthalene was detd. for 3 Hg lines. There is a slight convexity toward the temp. axis of the rotation-temp. curve which is the opposite of that obtained for the magnetic double refraction-temp. variation. The experimentally detd. values for the magnetic rotary dispersion agree fairly well with those calcd. from Mallemann's theory. F. W. LAIRD

Magnetic double refraction of phenol, naphthalene and phenanthrene in the molten state. CONSTANTIN SALCEANU. *Compt. rend.* **191**, 486–8(1930).—By means of the exptl. arrangement of Cotton and Dupouy (cf. *C. A.* **24**, 3682) the magnetic double refraction of phenol at 49° was found to be 1.10°; of naphthalene at 106°, 3.45°; and of phenanthrene at 104°, 7.85°. The double refraction is given at several other temps for each compd., as are the ratios of the double refraction to that for nitrobenzene. The Cotton-Mouton consts. also are given. E. G. VANDEN BOSCH

Molecular field and atomic order in ferromagnetic crystals and in hydrogenated iron. L. W. MCKEEHAN. *Nature* **126**, 952–3(1930).—"The 2 possible ways in which magnetization may change are (1) by reversals, without sensible magnetoresistance changes or magnetostriction, and with small but definite hysteresis losses probably closely conditioned by elec. cond.; and (2) by rotations through less than 180°, with magnetoresistance and magnetostriction, with hysteresis losses of important amount

largely controlled by mechanical strains inherent or induced by applied stresses, and possibly subject to catalytic acceleration." GREGG M. EVANS

Generalization of the virial of Clausius. S. RAY. *Bull. intern. acad. polonaise* **1929A**, 233–9.—Math. The virial of Clausius is applied to the case of a vol. of gas enclosed within impervious walls disposed symmetrically with respect to the coördinate axes. B. C. A.

Entropy, elastic strain and the second law of thermodynamics; the principle of least work and of maximum probability. W. S. KIMBALL. *J. Phys. Chem.* **35**, 611–23 (1931); cf. *C. A.* **23**, 5359.—A new mech. aspect of entropy with reference to a simple, fully excited gas is obtained from the geometrical expression for wt. and by taking strains to include unit extensions in velocity and momentum space as well as ordinary space. The second law of thermodynamics and the automatic increases of entropy that it represents are attributed to increased strain under the action of corresponding stresses, rather than to the unsatisfactory ergodic hypothesis as in statistics. H. F. JOHNSTONE

The nature of the effect of the addition of salt upon the surface tension of sodium taurocholate solutions. MASAIE SHIONO. *J. Biochem.* (Japan) **12**, 317–39(1930).—Various salts added to a soln. of Na taurocholate lower its surface tension to different degrees. At higher concns. the effect is conditioned upon the hydration of the salts while at much lower concns. the effect depends upon the nature of the cations, those forming less dissociable salts being more effective in depressing the surface tension of the Na taurocholate solns. The surface tension of taurocholic acid or of its salts is due to the accumulation of their mols. at the surface of soln. The min. surface tension of the Na, Ca and Cu salts differ from each other, indicating that the surface activities of the films of these various taurocholates differ. S. MORGULIS

Binary mixtures. L. PIATTI. *Z. physik. Chem.*, Abt. A, **152**, 36–46(1931).—The b. p. compn. and the viscosity-compn. diagrams at various temps. were detd. for mixts. of *m*-cresol and PhOMe with EtOH and C_6H_6. At 0° the viscosity curves are nearly straight lines but at higher temps. the deviation is marked. The results are discussed with respect to mol.-compd. formation. V. F. HARRINGTON

Maximum velocity of evaporation of liquids evaporated on heated metallic surfaces. ZOFJA BLASZKOWSKA. *Roczniki Chem.* **10**, 691–713(713–4 French)(1930).—The phenomenon of max. velocity of evapn. of liquids was investigated by evapg. 10 liquids (Et_2O, Me_2CO, $CHCl_3$, MeOH, EtOH, CCl_4, C_6H_6, H_2O, $C_6H_5CH_3$ and C_6H_5Cl) over Al, Fe and brass surfaces heated several tenths of a degree above the boiling temp. On heating the metallic surfaces to temps. still higher a rapid diminution of the velocity of evapn. can be observed; this is due to the Leidenfrost phenomenon, which makes the evapn. very difficult. A small elec.-furnace was constructed which served to study and det. with precision the so-called "temp. corresponding to the max. velocity of evapn.," that is, the temp. of the metallic surface at which the velocity of evapn. attains a max. A series of curves is drawn showing the relation between the time of evapn. of 1 drop of the liquid (approx. 0.01 g.) and the temp. of the metallic surface on which the evapn. takes place. The curves are marked by a min. time of evapn. of the liquid (corresponding to the max. velocity of evapn.) in a certain temp. interval lying above the b. p. of the liquid. On the basis of these exptl. results a technical method is elaborated for a very rapid evapn. of liquids by heating the metallic surfaces to the "temp. corresponding to the max. velocity of evapn." 600 l. of C_6H_6 or $C_6H_5CH_3$ could be evapd. in one hr. per 1 sq. m. Also in *Bull. intern. acad. polonaise* **1930A**, 188–90. J. KUČERA

The rate of shear in capillary tubes. WINSLOW H. HERSCHEL. *J. Rheol.* **1**, 506–7(1930).—A brief math. note suggested by Williamson's paper (cf. *C. A.* **24**, 5193). EUGENE C. BINGHAM

Rheology index. EUGENE C. BINGHAM. *J. Rheol.* **2**, 10–107(1931).—A list of about references to rheological literature arranged alphabetically according to authors. The subjects of papers are included and in many cases the location of abstracts of papers are cited. EUGENE C. BINGHAM

Some fundamental definitions of rheology. EUGENE C. BINGHAM. *J. Rheol.* **1**, 505–17(1930).—This is a revised form of definitions drawn up for the comm. on plasticity, consistency, etc., of the Am. Soc. for Testing Materials (cf. *Proc. Am. Soc. Testing Materials* **29**, II(1929); *C. A.* **23**, 4119, 4861). EUGENE C. BINGHAM

Plasticity and criteria of molecular aggregation. S. E. SHEPPARD. *J. Rheol.* **1**, 471–84(1930); cf. *C. A.* **24**, 1783.—S. discusses the work of Staudinger and his co-workers, Whitby and his co-workers, Kraemer and Williamson, Fikentscher and Mark and attributes the solvation of colloids to monomol. adsorbed layers formed by dipole

orientation for those conditions under which the colloidal solns. obey Poiseuille's law, *e. g.*, in gelatin above 40°. In gelatin above 40° the fluidity steadily increases with time. If the solvation were increasing there would be a dilation, but it is not observed; hence it is inferred that only the linear dimensions of the macromols. are changed.
EUGENE C. BINGHAM

Structure of material in the solid state. ADOLFO FERRARI. *Scientia* [3], **48**, 371-82(1931).—A review is given of the present ideas of crystal structure applied to such cryst. properties as at. radii, amorphism, isomorphism, polymorphism and temp. of fusion.
DON BROUSE

X-ray investigation of the cubic modification of the perchlorates. K. HERRMANN AND W. ILGE. *Z. Krist.* **75**, 41–66(1931).—The cu. form of the perchlorates belongs to either space group T_d^2 or T^2. There are 4 mols. in the unit cell, whose dimensions are as follows: $KClO_4$—7.47 A. U.; NH_4ClO_4—7.63 A. U.; $TlClO_4$—7.61 A. U.; $RbClO_4$—7.65 A. U.; $CsClO_4$—7.96 A. U.; $NaClO_4$—7.25 A. U.; $AgClO_4$—6.92 A. U. General at. positions are given. For NH_4ClO_4 and $NaClO_4$ it is shown that the ClO_4 group forms a close-packed tetrahedron, with the Cl atom at the center. L. S. R.

The influence of RO_4^{--} and related ions on the crystalline form of sodium chlorate. HAROLD E. BUCKLEY. *Z. Krist.* **75**, 15–31(1930)(in English).—$NaClO_3$ normally grows as cubes, with rare appearance of 110, 210 and 111. Expts. using a wide range of impurities show this cubic habit to be rather unresponsive to modification. However, ionizable substances of the RO_4^{--} type cause the 111 planes to appear at the expense of 100. There is a certain crit. concn., *C*, at which the 100 faces just disappear. *C* values are as follows: $3SeO_4$ ions, $2ClO_4$, $1Cr_2O_7$, $1CrO_4$ to $1ClO_3$; $1SO_4$ to $7ClO_3$; $1S_2O_3$ to $20ClO_3$; $1B_4O_7$ to $60ClO_3$; $1S_2O_6$ to $1000ClO_3$. MoO_4, MnO_4, PO_4, AsO_4, CO_3 and SiO_3 have no effect. The effect is attributed to the ions adhering to the surface by means of their O_3 triangles in place of the ClO_3 ions, the configuration of the remainder of the ions causing the variations.
L. S. RAMSDELL

The crystal structure of bixbyite and the C-modification of the sesquioxides. LINUS PAULING AND M. D. SHAPPELL. *Z. Krist.* **75**, 128–42(1930)(in English).—The unit of structure of bixbyite has a = 9.365 A. U. and contains 16 $(Mn, Fe)_2O_3$. The space group is T_h^7. On the assumption that the (Fe, Mn)—O and O—O distances cannot be less than 1.80 A. U. and 2.40 A. U., resp., a final choice is made between 2 possible arrangements, both of which are compatible with the x-ray data. The chosen structure has 8 (Mn, Fe) in 8*e*; 24 (Mn, Fe) in 24*e* with $u = -0.030 \pm 0.005$; 48 O in x, y, z, etc., with $x = 0.385$, $y = 0.145$, $z = 0.380 \pm 0.005$. A detailed description of the structure is given, together with interatomic distances and dimensions for the similar oxides of Mn, Sc, Y, In, Tl, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu The structure for this series as detd. by Zachariasen (*C. A.* **23**, 1790) is shown to be in error.
L. S. RAMSDELL

The crystal structure of columbite. J. H. STURDIVANT. *Z. Krist.* **75**, 88–108 (1930)(in English).—A crystal of columbite-tantalite (Fe, Mn) $(Cb, Ta)_2O_6$ was found to have an orthorhombic unit with dimensions a = 5.082 A. U., b = 14.238 A. U., c = 5.730 A. U., contg. 4 mols. The space group is V_h^{14}. By the use of the coördination theory and the theory of close packing, several structures were derived, one of which best fits the exptl. data. It consists of octahedra of O ions about a metal ion; each octahedron shares 2 edges with adjoining ones to form strings of either Cb octahedra alone or Fe octahedra alone; the strings are united by the sharing of octahedra corners.
L. S. RAMSDELL

The structure of enstatite, $MgSiO_3$. B. E. WARREN AND D. I. MODELL. *Z. Krist.* **75**, 1–14 (1930)(in English).—From rotation photographs of a hypersthene crystal the axial lengths were calcd. as a = 18.20 A. U., b = 8.86 A. U. and c = 5.20 A. U. If holohedral symmetry is assumed, the space group is V_h^{16}. There are 16 mols. of $(Mg, Fe)SiO_3$ in the unit cell. Coördinates of the at. positions and interatomic distances are given. There is a close relation between this structure and that of diopside. With slight alterations the whole diopside cell corresponds to $^1/_2$ unit of enstatite, with Ca replaced by Mg. The unit cell of the orthorhombic pyroxene corresponds very nearly to 2 cells of monoclinic pyroxene, joined on the (100) plane through a glide plane of reflection. Enstatite has the single type of Si-O chain characteristic of the true members of the pyroxene group.
L. S. RAMSDELL

The crystal structure of benzene and its relation to that of thiophene. II. G. BRUNI AND G. NATTA. *Atti acad. Lincei* **11**, 1058–62(1930); cf. *C. A.* **24**, 2353. The crystal structure of C_6H_6 was detd. at —170° by the powder method with a Ca anticathode. The axial ratios were $a:b:c$ = 0.771:1:0.708; these values closely

checked those obtained by Cox (*C. A.* **22**, 4296) 0.771:1:0.704. These values are near those of thiophene, 0.757:1:0.757, while the vols. of the unit cells are 471 and 498 × 10^{-24} cc., resp., which would explain the formation of solid solns. of these 2, although there is no true isomorphism. A. W. CONTIERI

Lattice constants of mixed crystals of copper-nickel. W. G. BURGERS AND J. C. M. BASART. *Z. Krist.* **75**, 155–7(1930).—Precision measurements on a series of mixed crystals of Cu-Ni show a slight deviation from the values as predicted by Vegard's additive law. The max. deviation was 0.008 A. U. L. S. RAMSDELL

Anomalous crystallized mixed systems of the type iron ammonium chloride. A. NEUHAUS. *Chem. Erde* **5**, 554–624(1930).—NH_4Cl may take up varying amts. of $FeCl_3.H_2O$ (up to 7.5%), giving distorted cu. crystals showing optical anomalies. Crystals of a similar nature are formed with $CoCl_2.2H_2O$ (up to 19%) and $NiCl_2.2H_2O$ (up to 14%). Conclusion: These are not double salts nor true mixed crystals, but rather represent the inclusion of foreign matter along certain faces in the NH_4Cl crystals. The systems $FeCl_3$–H_2O, $CoCl_2$–H_2O and $NiCl_2$–H_2O were also studied in this connection, and data are given for some new cryst. hydrates. B. C. A.

Artifically colored crystals as examples of the so-called anomalous mixed crystals. K. SPANGENBERG AND A. NEUHAUS. *Chem. Erde* **5**, 437–528(1930).—A detailed review is given of artificially colored mixed crystals (*e. g.*, $FeCl_3$ in NH_4Cl, methylene blue in $Pb(NO_3)_2$, etc.) and of the influence of such substances in soln. on the habit of the crystals. It is considered that these are not true mixed crystals but represent an inclusion of foreign material adapted to the structure of the host. In this connection the composite crystals formed by the regular intergrowths of various minerals and salts are considered in detail from a structural viewpoint. B. C. A.

Distribution of foreign substances in crystals. J. NOTHHAFT AND H. STEINMETZ. *Chem. Erde* **5**, 225–32(1930).—The distribution of color and inclusions in various minerals and in crystals of $Pb(NO_3)_2$ grown from solns. contg. various coloring matters is described. In fluorite the bands of color parallel to the cube faces are built up of minute fibers perpendicular to the cube faces, and there are diagonal areas in the crystal free from inclusions. The observations are discussed in connection with the growth of crystals. B. C. A.

Anomalous crystallized mixed systems with organic components or of an organic component in an inorganic host. A. NEUHAUS. *Chem. Erde* **5**, 529–53(1930).—Various inorg. salts when crystd. from soln. may take up org. coloring matters; *e. g.*, $Ba(NO_3)_2$, $Pb(NO_3)_2$ and $Sr(NO_3)_2$ readily take up methylene blue, NaCl and KCl take up murexide, and K_2SO_4 takes up ponceau red and Bismarck brown. Similar anomalous crystals are also formed by certain pairs of org. compds., *e. g.*, $C_{10}H_8$ and dihydronaphthalene. Crystals of this kind are considered in detail especially from a structural point of view. B. C. A.

The points on the isotherms of electrical conductivity of metallic mixed crystals. G. GRUBE AND J. HILLE. *Z. anorg. allgem. Chem.* **194**, 179–89(1930).—The relations between the constitution of binary alloys and their elec. cond. are so far explained that this property may be used to obtain constitution diagrams in cases where thermal analyses do not yield clear results. If a non-dissocd. intermetallic compd. seps. from a continuous series of mixed crystals of 2 metallic components which in turn forms mixed crystals with the components, no displacement of the max. of the cond. isotherm occurs with temp. if both components lower the transformation temp. of the compd. If the transformation temp. is increased by both components, 2 rounded max. occur on the isotherm at temps. adjacent to the transformation temp. of the pure compd., which lie at lower and higher concns. than the compd. If the transformation temp. is increased by one component and lowered by the second, there may occur a flattening and displacement of the max. to other concns. at adjacent temps. The heterogeneous decompn. regions adjoining the α- and β-mixed crystals have the same cond. at the same temp. For the establishment of the phase boundaries, the temp.-resistance curve rather than the cond. isotherm is used. A displacement of the max. of the cond. isotherm with the temp. may also occur if both components lower the transformation temp. of the compd., only however if the compd. is partly dissocd. into its components. ALLEN S. SMITH

Conditions of growth of crystals of difficultly soluble substances. I. D. KURBATOV. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, 429–35(1930).—Conditions of accelerating or decelerating the process of crystn. of difficultly sol. substances were studied, and a distinction was drawn between the methods employed in the labs. and those natural conditions that give rise to the growth of large crystals. A new lab. method for obtaining large crystals, based on exptl. evidence and theoretical considerations, is pro-

posed. Large crystals can be obtained best by using solns. of non-equiv. ionic concns. of the substance to be crystd. To feed crystals formed in satd. solns. and to prevent formation of new centers of crystn., non-equiv. solns. should be used. They present 2 factors favoring growth of large crystals: (1) increase of the soly. product, and (2) decrease of the no. of mols. that can crystallize out of the soln. B. N. DANILOFF

Magnitudes of state of oxygen at low temperatures. FRITZ SCHMIDT. *Z. Ver. deut. Ing.* **74**, 1710(1930).—The thermodynamic properties of O at temps. between +200° and —200° and at pressures from 1 to 150 atms. were detd. by interpolating and extrapolating isothermic curves. The following values for the most important properties were derived:

	Temp.	Pressure	Sp. Gravity γ in kg./dm.³
M. p.	−218.4	1 mm Hg.	1.305
B. p. at atm pressure	−182.8	760 Hg.	1.140
Crit. point	−118.8	51.35 atm.	0.430

The sp. heats were derived from the pv diagrams: sp. heat of liquid c_p = 0.395 kg.-cal./kg. °C at —200° and the heat of vaporization r = 51 kg.-cal./kg. at —182.8° and 760 mm. Hg. M. MCMAHON

The compressibility of nitrogen and hydrogen at pressures up to 5000 atmospheres. JAMES BASSET AND R. DUPINAY. *Compt. rend.* **191**, 1295–7(1930).—The vols. of H_2 and N_2 that occupy 1 cc. at 16° and 1000 kg. per sq. cm. are given at pressures ranging from 1000 to 5000 kg. per sq. cm. Similarly the vols. of H_2 and N_2 that initially occupy 1000 cc. at 0° and 76 cm. are given for these same high pressures. The values for H_2 are in accord with those of Amagat. App. for subjecting gases to 10,000 kg. per sq. cm. and to 25,000 atm. is under construction. F. W. LAIRD

The compressibility isotherms of methane at pressures to 1000 atmospheres and at temperatures from —70° to 200°. HAMLINE M. KVALNES AND V. L. GADDY. *J Am. Chem. Soc.* **53**, 394–9(1931).—Published data were checked and addnl. values obtained to cover 9 temps. and 26 pressures at each temp. B. A. SOULE

A method for the determination of critical temperatures and the critical temperature of hydrogen fluoride. P. A. BOND AND DELLA A. WILLIAMS. *J. Am. Chem. Soc* **53**, 34–7(1931).—The crit. temp. of HF is 230.2°, as detd. by a new method in which the pointer of a balance is set in motion upon the appearance of the liquid phase. The method, which may be used for substances attacking glass, has been checked (*a*) directly on SO_2, (*b*) by substituting in van Laar's equation, $T_c/T_b = K$, values from HF and obtaining for K a value (1.72) very close to that for HCl, HBr and HI. DON BROUSE

The activation energy of adsorption processes. HUGH S. TAYLOR. *J. Am Chem. Soc.* **53**, 578–97(1931); cf. *C. A.* **25**, 629.—Adsorption is not necessarily rapid The assumption that adsorption processes possess their own characteristic activation energies leads to a general theory of adsorption that applies equally well to the so-called primary, or irreversible, and to the secondary, or reversible, adsorption. Those adsorptions are secondary or reversible that have small heats of adsorption and small activation energies. In general, it is the adsorptions with the higher energies of activation that are important in catalytic change. F. L. BROWNE

Velocity of adsorption processes and the problem of promoter action. HUGH S TAYLOR AND ARTHUR T. WILLIAMSON. *J. Am. Chem. Soc.* **53**, 813–4(1931); cf. preceding abstract.—On an active MnO catalyst H_2 is adsorbed immeasurably slowly at 0° and 100°; at 180° the initial rate of adsorption is 8 mm. per hr. and at 305° 78 mm. per hr., corresponding to an activation energy of approx. 10,000 cal. A MnO-Cr_2O_3 catalyst shows an extremely low rate of absorption at 0° but at 184° it has risen to approx. 100 mm. per min. or an increase of about 700-fold by reason of the promoter action of the Cr_2O_3. In considering the mechanism of promoter action attention must be paid not only to extension of surface but also to the velocities with which the activating adsorptions occur. C. J. WEST

Surface films. N. K. ADAM. *Nature* **126**, 955–6(1930).—A comment on a review by Langmuir of A.'s book "The Physics and Chemistry of Surfaces" (cf. *C. A.* 24, 2354). A. disclaims as much disagreement with L. as is inferred by the latter. The liquid expanded state is intermediate between the condensed and the expanded states, and it is to this state only that the statements as to competition between the chains and heads of mols. apply. A. however, reaffirms his belief in the possibility of definite angles of tilt. GREGG M. EVANS

Dialysis, ultrafiltration, osmosis and their applications. A. BOUTARIC. *Chimie & industrie* **24**, 1295–303(1930).—A review. A. PAPINEAU-COUTURE

Finely divided solids as emulsifiers. J. L. VAN DER MINNE. *Chem. Weekblad* **27**, 651–2(1930).—The conclusions of Carrière (*C. A.* **25**, 858) are compared with those of M. (Dissertation Utrecht, 1928); cf. *C. A.* **22**, 2312. B. J. C. VAN DER HOEVEN

A method for measuring average particle size of emulsions. WHEELER P. DAVEY. *J. Phys. Chem.* **35**, 115–7(1931).—When a drop of an oil-in-water emulsion falls into clean neutral water with force enough to break the surface of the water, the drop maintains its identity for some time. A drop of emulsion deposited gently on the water spreads very rapidly. When spreading is complete a layer one colloidal particle deep seems to exist on the surface of the water If it is assumed that the colloidal particles remain spherical, the surface covered by a known quantity of emulsion gives the information necessary for calcg. the diameter of the particles. The emulsion must be dil. enough to avoid aggregation of particles and concd. enough to furnish sufficient particles to cover the surface. Samples of an emulsion at different dilns. indicate the same particle size. The procedure is the same as that employed by Langmuir with oil films. F. E. BROWN

Influence of electrolytes on the dispersion of clays. F. ALLAM. *Chem. Erde* **5**, 276–318(1930) —The results are given of a no. of expts. on the permeability and flocculation of a clay from Silesia with various salt solns. B. C. A.

Liquid ammonia as a lyophilic dispersion medium. II. Ammono-gels of cellulose acetate. ROBERT TAFT AND JESSE E. STARECK. *J. Phys. Chem.* **35**, 578–87(1931).—Sols contg. as much as 60 g. cellulose acetate in 100 cc. of liquid NH_3 were prepd. A mixt. of acetates is more readily dispersed than the cellulose triacetate. The sols of higher concn. were prepd. by evapn. of part of the solvent. There seems to be no limit to the possible concn. of sol. Dil. sols are clear, colorless and mobile; concd. sols are viscous, translucent and light brown. On warming, the viscosity decreased at first but after several hours the sols changed irreversibly to white opaque gels. The time required for gelation is a function of concn., temp., H_2O content and age. Gels were formed by cooling sols to about —60°. These gels were reversible on warming to a temp. somewhat above that of their formation. Heat-irreversible gels seemed to have changed chemically and to have adsorbed water. F. E. BROWN

Determination of the hydrogen-ion concentration in gold sols. T. R. BOLAM AND J. CROWE. *J. Phys. Chem.* **35**, 602–10(1931).—By using a specially designed H electrode requiring only a little soln., it was found possible to det. the p_H values but the sol must be either sufficiently acid or suitably buffered in order to obtain steady and reproducible results. Probably there was some foreign material present during the expts. of Adolf and Pauli, and of Tartar and Lorah, who were unable to obtain satisfactory values. W. T. H.

Solution of colloidal particles by dilution of the sol. ADOLPH J. RABINOVICH AND V. A. KARGIN. *Z. physik. Chem.*, Abt. A, **152**, 24–35(1931).—The previously discovered property of acidoid sols of dissolving on diln. is confirmed with WO_3 and V_2O_5 and the results were checked by electrometric and spectrographic measurements. Because of the formation of H ion by hydration of the inner layers of the particles, these sols behave similarly on diln. of their buffered solns.: their p_H remains const. until the particles are in soln. The Tyndal effect then disappears. The not purely acidoid sols, As_2S_3 and Fe_2O_3, do not behave thus. V. F. HARRINGTON

Polyatomic oxy-combinations that form during the synthesis of electronegative hydrosols. V. Oxy acids. A. V. DUMANSKII AND A. G. YAKOVLEV. *Bull. soc. chim.* [4], **47**, 1211–6(1930); cf. *C. A.* **24**, 3939, 4977.—Triangular diagrams for the sols of the systems comprising $FeCl_3$ 0.1 *N* [A], NaOH and NH_4OH 0.1 *N* [B], and the Na salts of acetic glycolic, succinic, malic, tartaric and citric acids 0.1 *N* [C], are worked out. The oxy acids give peptization diagrams with regions of deposition, of cloudy electroneg. sols, of electroneg. sols without pptn., and of electropos. sols with and without pptn. Equil. is reached very slowly in these systems. The peptizing action is of the order: tartaric acid > glycolic acid > malic acid > citric acid. Increasing the OH groups increases the peptization properties as shown by tartaric, malic and succinic acids. Substituting NH_4OH for NaOH increases the peptizing action. Thirteen diagrams are shown. Also in *J. Russ. Phys.-Chem. Soc.* **62**, 1665–70(1930). H. W. WALKER

The mechanism of formation of colloidal silver. HELEN Q. WOODWARD. *J. Phys. Chem.* **35**, 425–31(1931).—When Ag sols are formed by the Bredig method, Ag reacts with the anion present to form salts, complexes or AgOH. Expts. are reported for arc-

ing in H_2O and in solns. of 14 electrolytes. When the Ag salts form, the cations of the stabilizing salt form bases. In water AgOH forms. F. E. BROWN

Chromium hydroxide. JULJUSZ LISIECKI. *Roczniki Chem.* **10**, 736–42(742 German)(1930).—A Cr_2O_3 sol with as small amt. of peptizing agent as possible was prepd. in a pure and concd. form without dialysis. The excess of peptizing agent can be removed by satn. with a corresponding amt. of gel, in the form of dispersoid instead of by dialysis. The time of prepn. is shortened from several weeks to several hrs. and the exptl. conditions are quant. By this method various metal oxide hydrosols of any concn. can be prepd. with any ratio of the peptizing gel to peptizing agent. A metal oxide hydrosol differs from the dispersoid although it does belong to the disperse systems. The dispersoids show different cataphoretic properties as compared with hydrosols and are not pptd. by electrolytes. As Bredig's expts. have clearly proved, stable hydrosols cannot be prepd. without peptizing substances. Besides mechanical or elec. dispersion, chem. dispersion or peptization is necessary to prep. a permanently stable hydrosol J. KUČERA

Hydrosol of silicic acid. I. Hydrosol made from ethyl silicate by hydrolysis. KENKYO INABA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, 1–15(1930).—Unless the ethyl silicate, prepd. from $SiCl_4$ and EtOH and purified by vacuum distn., contains some HCl, the H_2SiO_3 hydrosol resulting from hydrolysis is unstable. Hydrolysis of pure ethyl silicate in the presence of such peptizing agents as NaOH, KOH, HCl and H_2SO_4 (but not H_2CO_3 or org. acids) gives stable sols. The 2 types of sols studied were prepd. by hydrolysis of ethyl silicate in the presence of (1) HCl and (2) NaOH. Each sol was purified by electrodialysis through a parchment membrane. The highest concn. of SiO_2 that can be stabilized by HCl is 7–8%. The HCl cannot be removed completely without causing coagulation; *e. g.*, a sol contg. 2.56% SiO_2 becomes unstable when the HCl concn. is reduced below 0.0001 *N*. Electrodialysis of NaOH-stabilized sols contg. more than 14% SiO_2 gives unstable sols; with less SiO_2 present strictly neutral sols of high stability can be produced. Because of the relatively high elec. cond. and low viscosity of the neutral sols, the particles must be smaller in the neutral than in the acidic type of H_2SiO_3 hydrosol. This is confirmed by the fact that the amt. of SiO_2 passing through the parchment during electrodialysis is negligible in the acidic but very large (30–50%) in the neutral sols. The stability of the acidic sols varies with the HCl and SiO_2 concns. Addn. of small amts. of HCl to the neutral sols tends to increase the stability. **II. Electrical properties of the hydrosol of silicic acid.** *Ibid* 16–31.—The 4 sols used differed in method of prepn.: *A* was the acidic and *B* the neutral sol described in the preceding abstr.; *C* was made by hydrolysis of $SiCl_4$; *D* was made by dissolving in NaOH soln. some of the H_2SiO_3 sol from hydrolysis of $SiCl_4$ and then decompg. the sodium silicate with HCl. Each sol was purified by electrodialysis: sol *C* resembled *A* in requiring some HCl to stabilize it; although *D* could be obtained in neutral form, not all of the NaCl could be removed. Electrophoresis measurements were made in a U-tube of the Burton type (diam. of tube 1.1 cm. and distance between electrodes 23 cm.). The *movement of the boundary*, which was practically invisible to the naked eye, *was detd. by photography in ultra-violet light*, with an ordinary plate. Under a potential gradient of 1 volt/cm. at 25°, the migration velocities $\times 10^5$ of the boundary (toward the anode) in cm./sec. were 2, 23, 1 and 11 for sols *A*, *B*, *C* and *D*, resp., each contg. approx. the same amt. SiO_2 (0.3–0.4%). The corresponding conductivities (units not specified) were 1.97×10^{-4}, 0.675×10^{-4}, 1.15×10^{-4} and 0.688×10^{-4}. Variation of the HCl concn. (c) revealed a max. migration velocity (x) at low c in sols *A*, *B* and *C*. With increasing c in sols *B* and *D*, x decreased to zero and reversed sign; in sols *A* and *C*, the max. x was followed by an abrupt decrease and then a gradual decrease through zero. The effect of KCl, $BaCl_2$, $CeCl_3$ and $ThCl_4$ on neutral sol *B* was studied. The effect of KCl and $ThCl_4$ upon x was similar to that of HCl. With $BaCl_2$, coagulation took place before an isoelec. point was reached. At concns. of 0.0003–0.0004 *N* $CeCl_3$ the H_2SiO_3 moved toward the cathode, but outside these limits the sol moved toward the anode. The viscosity of the sol shows a min. in the neighborhood of the isoelec. point. The adsorption of neg. ions (Cl or silicate) is as important a stability factor as the charge or hydration and its effect is most marked near the isoelec. point. OSCAR T. QUIMBY

The syneresis of silica gel. J. FERGUSON AND M. P. APPLEBEY. *Trans. Faraday Soc.* **26**, Pt. II, 642–55(1930).—The syneresis of SiO_2 gel was studied under several conditions. The vol. of syneretic liquid expressed exactly equals the decrease in vol. of the gel. The vol. of liquid when plotted against time gave an S-shaped autocatalytic curve. The velocity of syneresis, and the total vol. of liquid expressed were greater, the greater the original SiO_2 concn. of the gel at the time of setting. The

velocity of syneresis was approx. doubled for each 10° rise in temp. The initial velocity of syneresis was greater the more alkaline the gel, but the total vol. finally expressed was greater the more acid the gel. The hydration of the micelles was one mol. of water to one mol. of SiO_2 in neutral gels. The hydration increased with alky., being two mols. of water to one of SiO_2 at a p_H 10. It is concluded that the progress of syneresis is detd. by two factors: (1) the tendency of SiO_2 micelles to consolidate further by the action of unsatd. residual valencies, and (2) the tendency of the structure to resist deformation. L. H. REYERSON

Coagulation of ferric oxide hydrosols. C. HARVEY SORUM. *J. Am. Chem. Soc.* **53**, 812(1931).—Polemical with Dhar (*C. A.* **24**, 5572). C. J. WEST

Pseudo- "irregular series" observed in colloidal gold solution. EIICHI IWASE. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 931–41(1930); (*Abstracts* 89 (in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, Nos. 275-6).—A colloidal Au soln. is prepd. by adding 10 cc. $AuCl_3$ soln. (0.6% $AuCl_3.HCl.4H_2O$) and reducing agent to 500 cc. distd. water stirred well at room temp. The soln. is heated and when it begins to boil KOH or HCl in various concns. is added to det. the influence of the addn. on the stability of soln. As the reducing agent, the following 5 compns. are selected: 3.5 $F^{10}_{0.2KOH}$ (3.5 cc. of soln. prepd. by adding 10 cc. formalin to 90 cc. 0.2 *N* KOH soln.) (I), 3 5 $F^{10}_{0.5KOH}$ (II) 6 $F^{10}_{0.1KOH}$ (III), 8 $F^{10}_{0.1KOH}$ (IV), and 8 $F^{10}_{0.2KOH}$ (V). When (I) is used, the colloidal soln. is stable as long as the concn. of alkali added is less than 1.2 millimol./l. and more than 5.6 millimol./l. The coagulation value of KOH is 21 millimol./l. In (I) and (II) systems the second stable region exists, in general, in the sphere of 5–8 millimol./l. and 4.5–6.5 millimol./l. In (IV) systems the soln. has comparatively a good stability when there is 6 millimol./l. of KOH in the ultimate concn. In (V) it shows a mere tendency to become stable. The addn. of HCl shows no special phenomenon. In each colloidal soln. coagulation values by $BaCl_2$ and NaCl and p_H are resp. measured. Though the phenomenon resembles the so-called "irregular series," it differs from it in that (1) colloidal particles in the second stable region seem to have the same neg. charges as those in the first stable region and (2) the phenomenon is observed only when the addn. is carried out in the course of the reaction of prepn. K. KONDA

Distribution of hydrogen and hydroxyl ions in gelatin cubes. E. J. BIGWOOD. *Compt. rend. soc. biol.* **102**, 600–1(1929); *Physiol. Abstracts* **15**, 11.—Gelatin cubes contg. phenol red were placed in solns. of weak NaOH plus phenol red. In 24 hrs. each presented a yellow center and a red peripheral zone, the thickness of which was the same in all blocks of different sizes. The p_H (8 to 10) of the soln. scarcely changed in the course of a week. In the second week the p_H changed, and in the blocks the acidity increased from the surface toward the center. The values of p_H in the cubes were comparable only when measured at corresponding distances from the surface. G. G.

Distribution of hydrogen and hydroxyl ions in gelatin columns. E. J. BIGWOOD. *Compt. rend. soc. biol.* **102**, 602-4(1929); *Physiol. Abstracts* **15**, 11–2.—The phenomena described in the preceding abstract were studied in the case of gelatin placed in tubes. In the case of agar jelly the red color reaches the bottom of the tube in 2 days. Agar does not react chemically with penetrating electrolytes. In the gelatin tubes a colorless portion remains at the bottom 25 days later. G. G.

Role of structure of jelly in permeability of ions. E. J. BIGWOOD. *Compt. rend. soc. biol.* **102**, 324–6(1929); *Physiol. Abstracts* **14**, 546–7.—The selective permeability of gelatin for cations and anions varies with the p_H of the liquid. The permeability depends on chem. affinities, and not on properties of a membrane of sepn., as suggested by Girard. Protein presents the properties of an active ion. For the setting up of a Donnan equil. it is unimportant whether the particles of protein be grouped in layers or scattered in the gelatinous phase. The eventual role of structure is indirect; it contributes to the semi-solid consistence of the gelatin and to the fixation of the non-diffusible proteic ions. G. G.

Abnormal osmosis at non-swelling membranes. I. K. SÖLLNER. *Z. Elektrochem.* **36**, 36–47(1930).—The magnitude of the p. d. between two solns. of electrolytes sepd. by a collodion membrane depends on the previous treatment of the collodion, whereby the size of the pores is affected. Such membranes contain fine pores of widely differing dimensions, thereby causing potentials to be set up which differ from place to place and from pore to pore and in consequence tend to establish closed-current circuits within and around the membrane. B. C. A.

The freezing of gel. KYOJI KINOSHITA. *Bull. Chem. Soc. Japan* **5**, 261–6(1930).—An app. is described in which solns. of gelatin were frozen. Cooling curves were obtained for solns. varying in concn. from 5 to 60% gelatin. Undercooling was pronounced and is attributed to inhibitive action of gelatin on the formation of ice crystals. Alternate ice and gel layers were found in solns. of concn. up to 15% gelatin. Up to this concn. the freezing temp. fell less than 3°. In the range of solns. between 15 and 30% the freezing temp. fell rapidly to −9.74°. It is concluded that there is almost no water in this region that can be sepd. by freezing. With still greater concn. of gelatin, water must be more firmly bound, since the f. p. is not depressed as rapidly. The f. p.-concn. curve is of an inverted S type. L. H. REYERSON

The vapor pressure of gels. E. H. BUCHNER. *Compt. rend.* **191**, 1323–4(1930).—Two tubes of gelatin gel were placed with their lower extremities in water. In one case the upper portion of the gel was exposed to satd. water vapor and in the other the end of the tube was closed. After one month the upper portions of both gels appeared firm and analysis showed that the upper extremity in each case contained more gelatin than the lower. Further, the final content of the upper ends was less than the original, indicating absorption of water in both cases through ascension. F. W. LAIRD

The vapor pressure of gels. PAUL BARY. *Compt. rend.* **191**, 1325–6(1930); cf. *C. A.* **24**, 4202.—A controversy with M. Buchner concerning the vapor pressure of a gel and its swelling liquid. F. W. LAIRD

The denaturation of albumin. WILDER D. BANCROFT AND J. E. RUTZLER, JR. *J. Phys. Chem.* **35**, 144–61(1931).—It has been assumed that proteins are irreversibly coagulated and that this process is really denaturation followed by, or accompanied by, coagulation. Denaturation was supposed to be a chem. change. It is found that there really is no denaturation and KI, KCNS, $(NH_2)_2CO$, NH_4CNS, $NaHCO_3$, CH$_3$CO and cane sugar peptize heat-coagulated egg-white sols. The peptized sols produce the same immuno-biological test as the original egg white, and have the same isoelec. points. Ether exts from egg-white sols a substance that acts like crude lecithin. After this substance was extd. from egg-white sols, immersion in boiling water for 15–20 min. failed to produce coagulation or cloudiness in a 10% sol. The coagulation and peptization of egg-white are reversible colloidal changes. An extensive literature review is included. F. E. BROWN

Scattering of light in protein solutions. I. Gelatin solutions and gels. K. KRISHNAMURTI. *Proc. Roy. Soc.* (London) **A129**, 490–508(1930); cf. *C. A.* **24**, 1578. Gelatin sols are considered polydisperse systems, in which part of the gelatin is present in the molecularly dispersed condition, and the rest as polymol. micelles. Cooling below 25° produces supersatn., as a result of which fresh particles are formed. These become large as a result of the condensation of the molecularly dispersed gelatin on them. During the gel-sol transformation the gel micelles are gradually dispersed to the original mol. condition. The variation of the intensity of the scattered light with the concn. of gelatin sols and gels was examd. The depolarization of the scattered light first decreases and then increases when gelatin sols are cooled to 10°. The significance of this in revealing the change in the size and shape of micelles is pointed out. The turbidity at the isoelec. point is caused by the aggregation of gelatin mole- F. E.

The colloidal structure of egg white as indicated by plasticity measurements. J. I. ST. JOHN AND E. L. GREEN. *J. Rheol.* **1**, 484–505(1930); cf. *C. A.* **24**, 5080. Egg white consists of a thin portion 32% and a thick portion 68%. The plastometer of St. John was used to study the apparent fluidity of both portions. The values given range from 0.167 to 0.305 for the thick portion and from 14.77 to 20.7 for the thin portion. The data were irregular. Some of the flow curves were far from linear; others indicated a neg. yield value and some had a neg. slope. Many expts. proved that it was impossible to obtain accurate values with the material sepd. by simple decantation even where the material was as fresh as possible. The effort was made to obtain consistent results by passing the material repeatedly through the pores of a Gooch crucible, but the results were unsatisfactory, since the fluidity obtained depended upon the no. of times the material was passed through the crucible. EUGENE C. BINGHAM

The temperature dependence of the solubility of inert gases in liquids. G. TAMMANN. *Z. anorg. allgem. Chem.* **194**, 159–61(1930).—Values for the expression $(1/\log l)(d \log l/dT)$ were obtained for He, Ne and A for temps. between 15° and 37°. If Q, the heat tone, is negligible in comparison to A, the external work, and the gas soly., l, is less than 1, *i. e.*, the concn. of gas in the liquid is smaller than that in the gas phase, the gas soly. increases with increasing temp. If Q is greater than the heat corresponding to the work, A, the soly. decreases with increasing temp. If $Q=0$, $(1/\log l)(d \log l/dT)$

should be equal to $-1/T$. This is found to be only approx. true for single values but for the av. of all the values for the soly. of the gases in the liquids used it is accurate. MeOH, EtOH, acetone, benzene and cyclohexane were used. The soly. of A in water decreases appreciably with increasing temp. The soly. of He is independent of the temp. between 15° and 30° while that of Ne decreases somewhat. ALLEN S. SMITH

Solubilities in hydrogen fluoride. P. A. BOND AND V. M. STOWE. *J. Am. Chem. Soc.* 53, 30–4(1931).—The solubilities of different salts in anhyd. HF (prepd. by distn. of dry KHF_2) were detd. in a "bomb" of Monel metal. The soly. of $LiHF_2$, expressed as mols. LiF per mol. HF, varies between 0.33 and 0.46 over the range of 0° to 40°. ZnF_2, MgF_2 and CaF_2 are very insol. KI reacts with liquid HF. CrF_3 is sol. to an undetd. extent. The solvent action of HF is similar to that of water. D. B.

The solubilities of alkali chlorides and sulfates in anhydrous alcohols. E. R. KIRN AND H. L. DUNLAP. *J. Am. Chem. Soc.* 53, 391–4(1931).—At 20° the solubilities of NaCl, KCl and Na_2SO_4 in MeOH, EtOH, PrOH, iso-PrOH, BuOH and iso-BuOH over the temp. range 20–50°, in moles times 10^2 of salt per mole of alc., are:

	MeOH	EtOH	PrOH	iso-PrOH	BuOH	iso-BuOH
NaCl	0.778	0.115	0.004	0.096	0.007	0.003
KCl	0.833	0.127	0.007	0.123	0.008	0.003
Na_2SO_4	0.555	0.143	insol.	0.089	insol.	insol.

B. A. SOULE

The solubilities of silver salts. KOSAKU MASAKI. *Bull. Chem. Soc. Japan* 5, 340–5(1930).—The soly. was detd. from the e. m. f. of the cell Ag | 0.01 *N* $AgNO_3$ | NH_4NO_3 (satd.) | Ag salt in 0.1 *N* K salt (except KCN which was 0.01 *N*) by the equation $e = 0.53 \times 2 \times 0.0581 \ln(ca/x)$, where 0.53 is the transference no., a is 0.93, c is 0.1 or 0.01 and x is the concn. of Ag^+ in the K salt soln. The mean e. m. f. and the soly. in mol./l. at 18° are: SCN 0.549 v. and 1.0×10^{-6}; Br 0.570 v. and 7.0×10^{-7}; CN 0.571 v. and 2.1×10^{-7}; and CO_3 0.205 v. and 1.1×10^{-4}. V. F. HARRINGTON

Theory of hydrotropy. CARL NEUBERG AND FRITZ WEINMANN. *Biochem. Z.* 229, 366–79(1930).—The ability of many salts of org. acids to make insol. substances, especially nonelectrolytes, water-sol. is designated as hydrotropy. Expts. with K salts of camphoric acid lead to the conclusion that this phenomenon is explained in the formation of a compd. between the hydrotropic salt and the dissolved substance. S. M.

Refraction of electric waves (λ = 12 cm.) in some electrolytes. K. ZAKRZEWSKI AND F. NAYDER. *Bull. intern. acad. polonaise* **1930A**, 30–41.—Measurements were made of the n of water and of aq. solns. for damped elec. waves of wave length 12 cm. The method employed consists in measuring the deviation produced in a narrow pencil of waves by a hollow glass prism filled with the liquid. The angle of the prism used was very small (3°56′), but large enough to eliminate inaccuracy due to reflections on the interior of the prism. The oscillator and detector were of the types described by Zakrzewski (*C. A.* 22, 2103). Within exptl. error the n of water for this wave length is the same as that for very long waves. The ns of Cu sulfate of up to 3% concn. and of NaCl solns. of up to 1% show no perceptible difference from those of pure water. B. C. A.

Electrical conductivity and viscosity of aqueous solutions. M. CHANOZ AND G. CRUZET. *Compt. rend. soc. biol.* 100, 1205–7(1929).—The elec. conductivities of solns. of KCl, NaCl, NaOH, Na_2SO_4, HCl, H_2SO_4 and $CuCl_2$ are reduced by addn. of sucrose, glycerol, agar or gelatin. B. C. A.

The thermodynamic properties of molten solutions of lithium bromide in silver bromide. E. J. SALSTROM AND J. H. HILDEBRAND. *J. Am. Chem. Soc.* 52, 4650–5(1930).—The energy changes of molten AgBr upon diln. with LiBr were detd. at mole fraction of LiBr varying from 0 to 0.89 between 450° and 600°. The free energy of formation of pure molten AgBr is given by the equation $\Delta F_0 = -21{,}510 + 6.7\ t$ between 440° and 575°. Density detns. of 0.5 mole fraction LiBr in AgBr were made between 517° and 555° and may be expressed by the equation $d^t = 4.504 - 0.000877\ t$. The results are discussed on the basis of simple assumptions as to ionization, but without taking into account any changes in interionic forces upon diln. E. H.

A discussion of the new view in the theory of solutions. GIOVANNI B. BONINO. *Atti III congresso naz. chim. pura applicata* **1930**, 231–48.—A review of the Debye-Hückel theory. J. B. AUSTIN

Dissociation theory of solutions. BERKELEY. *Nature* **126**, 313(1930).—Two formulas are given connecting the osmotic pressure, sp. vol., vol. of solute and the no. of g. mols. of solvent of salt solns. The formulas held for aq. solns. of cane sugar, α-

methylglucoside and isodulcitol at both 0° and 30° within variations of about 5%.
J. W. SHIPLEY

Proton and electron activity in solvents in general. GEROLD SCHWARZENBACH. *Helv. Chim. Acta* 13, 870–96(1930).—Modern conceptions of acids and bases are reviewed critically with 81 citations. Brönsted's definitions (*C. A.* 24, 2922) are somewhat modified. *Acids* are substances that can yield protons; *bases* are substances that can take up protons. Acids and bases may be either uncharged molecules or ions. An acid can yield a proton only in the presence of a base that can take it up. There are no free protons in solns. The proton is in homopolar combination with the acid and can probably penetrate even into the electron shell. The *normal acidity potential* of an acid, E_{ac}, is defined by the equation: $E = E_{ac} + RT/F.\ln[acid]/[base]$ in which E is the potential of a H_2 electrode and [acid] and [base] are the molar concns. multiplied by the activity coeffs. for the acid and base, resp. E_{ac} varies with the dielec. const. of the solvent but is independent of the acidity or basicity of the solvent. Strong acids have high E_{ac}, weak acids low E_{ac}. The difference in behavior between strong and weak acids is more marked the less basic the solvent. Thus HOAc behaves much like HCl in liquid NH_3, in H_2O the two acids differ materially, and in EtOH they differ still more markedly. In non-basic solvents E attains enormous and indefinite values because pure acids have no tendency to yield protons. Study of the acidimetry of such solns. is unprofitable. In the absence of solvent, acids have a self-buffering action. Study of such systems is very difficult because traces of impurities affect the potential enormously. Proton active substances in the pure state are always both basic and acidic to some extent at least, that is, they are amphoteric. F. L. BROWNE

The dissociation of strong electrolytes. III. Complete dissociation and optical properties. MORRIS B. JACOBS AND CECIL V. KING. *J. Phys. Chem* 35, 480–7(1931); cf. *C. A.* 24, 3417, 3606.—Additivity of color or light absorption, of refraction and of dispersion by the ions in solns. of strong electrolytes was not found in all cases. The most exact recent work shows discrepancies that must be explained by some means other than the degree of ionization. H. F. JOHNSTONE

The electrode potentials of the silver halide electrodes against a mixture of different halide solutions. JUZABURO TANIDA. *J. Biochem.* (Japan) 12, 411–8(1930).—The potential of Ag halide electrode immersed in a soln. contg. halogen ions, against a calomel electrode, is detd. mainly by the activity of the halogen ions of the largest mol. wt. Other halogen ions of smaller mol. wt. as well as anions other than the halides are indifferent. The potential is the same whether a AgCl, AgBr, AgI or a blank Ag electrode is used. S. MORGULIS

The reactions between atoms and molecules of nitrogen and hydrogen. W. STEINER *Z. Elektrochem.* 36, 807–14(1930).—An app. is described for separately activating N and H by elec. discharge, allowing the gases to react and finally collecting the products of reaction. H atoms show no reaction with N mols. The reaction between N atoms and H atoms gives NH_3, while the reaction between N atoms and H mols. furnishes N_2H_4 and NH_3, the former in much the smaller quantity. It seems probable that the NH_3 is formed through a triple collision: $N + H + X \longrightarrow NH + X'$, followed by the reaction of NH with mol. H: $NH + H_2 \longrightarrow NH_3$, while the N_2H_4 arises thus: $N + H_2 + X \longrightarrow NH_2 + X''$ and $2NH_2 \longrightarrow N_2H_4$. If such be the case, only every hundredth or thousandth triple collision between N and H_2 is effective in causing reaction. W. C. FERNELIUS

The action of carbonic acid, under pressure, on salts of the alkaline earth metals. I. Action on calcium phosphate. ERNST MÜLLER AND JULIUS KNÖFEL. *Z. anorg. allgem. Chem.* 194, 258–60(1930).—Under pressure a soln. of CO_2 decomposes secondary and tertiary Ca phosphate forming $Ca(HCO_3)_2$. At 60 atm. the soly. of $CaHPO_4$ is 6 times that at ordinary pressure. Soly. decreases with increase in temp. $Ca_3(PO_4)_2$ dissolves to the extent of 0.754 g. of P_2O_5 per l. *Bone ash* gives a soln. contg. 0.589 g. and 0.333 g. P_2O_5 per l. at 0° and 20°, resp. *Phosphorite* is sol. to the extent of 0.035 g. P_2O_5 per l. at 0°. The action on natural phosphates is less than that on synthetic samples because of the greater compactness of the former. **II. Action on alkaline earth silicates.** ERNST MÜLLER AND WALTER LUBBERGER. *Ibid* 261–7.—At 20° and 50 atm. 2 or more hrs.' action forms a soln. of bicarbonate equiv. to 3.49, 3.79 and 5.75 g./l. of $CaSiO_3$, $SrSiO_3$ and $BaSiO_3$, resp. At 0° the action is greatest, the soly. decreasing with increase in temp. The min. soly. is reached at 100°. $[H^+]$ is greatest at 30 atm. Hydrolysis and adsorption effects obscure the reaction mechanism. The soly. of ignited silicates at 50 atm. is 10 times that at ordinary pressure and $1/_5$ that of non-ignited samples. A method for the prepn. of carbonate-free silicates is given.
B. A. SOULE

Action of water vapor on sodium chloride at higher temperatures. STANISLAW BRETSZNAJDER. *Roczniki Chem.* **10**, 729–35(735 German)(1930).—The equil. of the reaction NaCl + H_2O = NaOH + HCl was detd. The value of K_p (= $p_{NaOH} \cdot p_{HCl}$) was found approx. 1.6×10^{-7} at 750°. J. KUČERA

Hydrolysis equilibria of triphenylchloromethane and triphenylbromomethane. The free energy of some reactions of triphenylchloromethane, triphenylbromomethane and triphenylcarbinol. J. O. HALFORD. *J. Am. Chem. Soc.* **53**, 105–12(1931).—A C_6H_6 soln. of the carbinol or carbinol halide was shaken in contact with an aq. soln. of the halogen acid of such strength that at equil. measurable concns. of carbinol and halide were produced. For the reaction $(C_6H_5)_3CCl$ (in C_6H_6) + $H_2O(g)$ = $(C_6H_5)_3COH$ (in C_6H_6) + HCl(g), K_{298} = 0.0518 and $\Delta F°_{298}$ = 1755 cal. For the reaction $(C_6H_5)_3CCl$ (s) + H_2O (g), = $(C_6H_5)_2COH$ (s) + HCl (g), K_{298} = 0.2195 and $\Delta F°_{298}$ = 900 cal. In obtaining these values K was detd. by analysis of equil. mixts. and $\Delta F°$ was calcd. from the equation $\Delta F° = -RT \ln K$. Similarly 14 other free energy relations of $(C_6H_5)_3COH$, $(C_6H_5)_3CCl$ and $(C_6H_5)_3CBr$ were detd. or calcd. These include solubilities and ionizations in C_6H_6 and in H_2O as solvents. F. E. BROWN

Double decomposition in the absence of solvent. I. The reciprocal system: AgCl + KBr $\rightleftharpoons$ AgBr + KCl. A. P. PALKIN. *Acta Univ. Asiae Mediae, Series VI, Chem.* No. **4**, 3–17(1930).—The reciprocal system AgCl + KBr $\rightleftharpoons$ AgBr + KCl was studied. The systems AgBr–AgCl and KBr–KCl form unbroken series of solid solns., and the systems AgBr–KBr and AgCl–KCl form eutectics. In order to det. the space equil. diagram of the quaternary system the following systems were studied and their phase diagrams detd. by means of heating and cooling curves: AgCl–KBr; eutectic (25.1 mol. percent KBr) at 320°. AgBr–KCl; eutectic (23.5% KCl) at 318°. AgBr (50% KBr + 50% KCl); eutectic (74.8 AgBr, 12.6% KCl, 12.6% KBr) at 302°. KBr–(70% AgBr + 30% AgCl); eutectic (54.1% AgBr, 23.2% AgCl, 22.7% KBr) at 318°. KCl–(35% AgBr + 65% AgCl); eutectic (26.4% AgBr, 49.1% AgCl, 24.5% KCl) at 321°. KBr–(42.5% AgCl + 57.5% AgBr), eutectic at 325°. (50% AgBr + 50% AgCl)–(50% KBr + 50% KCl); eutectic (10.9% KCl, 10.9% KBr, 39.1% AgBr, 39.1% AgCl) at 323°. (62.5% AgCl + 37.5% AgBr)–KBr; eutectic (43.2% AgCl, 28.8% AgBr, 23% KBr) at 323°. The liquidus surface of the entire quaternary system consists in 2 fields of crystn. intersecting along the eutectic line. The lowest point on the eutectic line (285°) corresponds to the eutectic compn. of the system AgBr–KBr. Shifting of equil. toward AgBr was noted; it was indicated on the open space model by the wave on the liquidus surface, and on the projection of the eutectic line, by the max. located nearer to the AgBr field. This agrees with the lower solv. of AgBr. **II. The reciprocal system: AgBr + KI $\rightleftharpoons$ AgI + KBr.** *Ibid* 19–40.—This system resembles the previously investigated system AgCl + KBr $\rightleftharpoons$ AgBr + KCl in relation to its general character. The binary systems AgBr–AgI and KBr–KI both form continuous series of solid solns. The binary system AgBr–KBr forms a eutectic (68 mol. percent AgBr, 285°), and the system AgI–KI forms an unstable compd. KI.4AgI, and a eutectic at 243°. Several diagonal sections of the "equil. square" of the quaternary system were studied by means of heating and cooling curves and the following results were obtained: The system AgBr–KI; eutectic (80.3 mol. percent AgBr) at 264°. AgI–KBr; eutectic (84 mol. % AgI) at 361°. AgBr–(50% KBr + 50% KI); eutectic (76.4% AgBr, 11.8% KBr and 11.8% KI) at 273°. AgI–(50% KBr + 50% KI); eutectic (81.4% AgI, 9.3% KI, and 9.3% KBr) at 336°. (70% AgI + 30% AgBr)–KI; eutectic (25.2% AgBr, 58.6 AgI, 16.2% KI) at 360°. (50% AgI + 50% AgBr)–KI; eutectic (42.3% AgI, 42.3% AgBr, 15.4% KI) at 334°. (6% AgBr + 94% AgI)–KI; eutectic (24.5% KI, 71% AgI, 4.5% AgBr) at 283°, and a transition point (21.5% KI, 73.8% AgI, 4.7% AgBr) at 285°. (7.5% AgBr + 92.5% AgI)–KI; eutectic (20.4% KI, 73.6% AgI, 6% ABr) at 300°, and the transition point (21.3% KI, 72.4% AgI, 5.9% AgBr) at 298°. (87.5% AgBr + 12.5% AgI)–KI, eutectic (17.8% KI, 71.9% AgBr, 10.3% AgI) at 253°. (74% AgBr + 26% AgI)–KI; eutectic (16.9% KI, 61.5% AgBr, 21.6% AgI) at 253°. The system (9% AgBr + 91% AgBr)–KI: the triple transition point of simultaneous crystn. of the solid soln AgI, AgBr, the solid soln. KI, KBr and the compd. KI.4AgI, occurs at 317°, and corresponds to the compn. 20.5% KI, 7.1% AgBr and 72.4% AgI. The displacement of equil. manifests itself here even more clearly than in the system AgCl + KBr $\rightleftharpoons$ AgBr + KCl; the system gives in the direction of the upper arrows a pos. thermal effect of 8.8 cal. The definite unstable compd. KI.4AgI, decomposable at 267°, is formed in the lateral binary system AgI–KI, and forms its crystn. field on the liquidus surface of the quaternary system. The latter, therefore consists of the 3 fields of crystn.: (*1*) solid solns. of KI and KBr, (*2*) solid solns. of AgBr and AgI, and (*3*) compd. KI.4AgI.

The eutectic lines meet at the triple point (317°, 20.5% KI, 7.1% AgBr, 72.4% AgI). The eutectic point of the system KI–AgI is, however, below the triple point (243° at 69.5% AgI). The projection of the eutectic line on the vertical AgBr–AgI plane rises rapidly to a max. (about 15% AgBr). The system described here as well as the system AgCl + KBr $\rightleftharpoons$ AgBr + KCl can be regarded as a representative of the type of systems that forms a transition from purely reversible to irreversible systems.

B. N. DANILOFF

Contribution to the study of the equilibrium, $FeS_2 \rightleftharpoons FeS + S$. FRANZ DE RUDDER. *Bull. soc. chim.* [4], 47, 1225–1254(1930).—The reversibility of the reaction, $FeS_2 \rightleftharpoons FeS + S$, was established by distn. of pyrites. A new synthesis was demonstrated. The intermediate compds., Fe_7S_8 to $Fe_{16}S_{17}$, postulated by others to be formed by the desulfurization of pyrites, do not exist and are considered as simple crystallographic forms of mixts. of FeS_2, FeS and S. During the distn. As_2S_3, present as an impurity, is given off together with SO_2 and H_2S formed from water present in the pyrites. Dissocn. curves for pressures of 9 mm. to 768 mm. with extreme temps. of 600° and 689°, resp., exhibit a clearly defined flat portion corresponding to the heat of absorption. The heat of reaction absorbed by the liberation of one S atom from FeS_2 is 18,513 cals. as calcd. from the Nernst equation. The roasting of pyrites in industrial furnaces gives FeS as an intermediate product, involving as a first reaction the dissocn. of pyrites.

H. W. WALKER

The affinity of metals for sulfur. I. The thermal equilibrium between hydrogen and the sulfides of iron, tin, cadmium, bismuth and antimony. E. V. BRITZKE AND A. F. KAPUSTINSKII. *Z. anorg. allgem. Chem.* 194, 323–50(1930).—The flow method of Jellinek (*C. A.* 19, 1513; 23, 5400) was used to study the above equil. between 400° and 1000°. By combining their data for the equil. const. (in the sulfide reduction) with those in the literature on the dissocn. const. of H_2S, B. and K. calcd. the partial pressure, p, of S_2 over the various sulfides. Within the range studied log p is a linear function of T. At ordinary temp. the metals stand in the following order of decreasing affinity for S: Cd, Sn, Fe, Sb and Bi. The mol. heats of formation (in large cal at 0°) from rhombic S and metal are: CdS 19.80; SnS 20.51; FeS 17.98; Sb_2S_3 42.50; Bi_2S_3 67.20.

OSCAR T. QUIMBY

Velocity of solution of aluminum in alkali solutions. M. TZENTNERSHVER AND W. WITTANDT. *Bull. intern. acad. polonaise* **1930A**, 50–61.—In agreement with Jablczyński, Hermanowicz and Wajchselfisz (*C. A.* 23, 3396), it is found that the rate of soln. of Al in NaOH soln. is proportional to the free surface area of the metal and to the sq. root of the NaOH concn. KOH, LiOH, $Ba(OH)_2$ and $Ca(OH)_2$ solns. all show the same order of reaction as the NaOH soln. $Ca(OH)_2$ shows a lower velocity of reaction than the corresponding concns. of the other hydroxides, but this is probably due to the formation of a protective film of the insol. Ca aluminate. With weak bases such as NH_3, ethylamine, diethylamine and triethylamine the reaction velocity is more closely proportional to the fourth root of the base concn., but this is proportional to the sq. root of the OH-ion concn. for weak bases. It is concluded that the velocity of soln. of Al depends only on the OH-ion concn., and this is supported by the fact that for different bases the rate of soln. is approx. proportional to the OH-ion concn. of the solns. This yields a convenient method of detg. the hydrolysis consts. of Na_2CO_3 and K_2CO_3, which are both about 1.4×10^{-4}. The reaction velocities have a temp. coeff. of about 2 for 10° and are independent of the rate of stirring of the soln.; hence it is a true reaction velocity which is measured and not a rate of diffusion.

B. C. A

Reactions involving hydrogen peroxide, iodine and iodate ion. I. Introduction. WM. C. BRAY AND HERMAN A. LIEBHAFSKY. *J. Am. Chem. Soc.* 53, 38–44(1931). A crit. review and discussion of various reactions of H_2O_2 in acid solns. contg. I and iodate or iodide are based on the following table:

Reaction of H_2O_2 with

	I^-	I_2	$I_2 + IO_3^-$	IO_3^-
10^{-1} *M* $\overset{+}{H}$	(*a*) —	(*d*) $I_2 \longrightarrow I^-$ very rapid	(*g*) $I_2 \longrightarrow I^-$ very rapid	(*j*) —
10^{-5} *M* $\overset{+}{H}$	(*b*) $I^- \longrightarrow I_2$ moderate	(*e*) $I_2 \longrightarrow I^-$ moderate	(*h*) —	(*k*) $IO_3^- \longrightarrow I$ and I^- very slow
10^{-1} *M* $\overset{+}{H}$	(*c*) $I^- \longrightarrow I_2$ faster than *e*	(*f*) —	(*i*) $I_2 \longrightarrow IO_3$ rapid	(*l*) $IO_3^- \longrightarrow I_2$ faster than *k*

...eparation of iodic acid. Preliminary rate measurements. WM. C. BRAY ...ULKINS. *Ibid* 44–8.—Values of K, the first-order rate const., are nearly

const., 0.6 ± 0.1 at concns. of I_2 from 1×10^{-3} to 3×10^{-4} M but always fall off markedly at lower concns. K is independent of the concn. of iodate, acid and peroxide within the ranges investigated. The simplest explanation is that the first-order reaction is the rate of hydrolysis of I and the that rapid decrease of K at low I concn. is due to the effect of the reverse reaction as the hydrolysis equil. is approached. The oxidation of I by H_2O_2 furnishes a direct method of investigating the rate of hydrolysis of I.
Don Brouse

The velocity of decomposition of the carbonato-tetrammine-cobaltic ion and its dependence on the hydrogen-ion concentration. Kai Julius Pedersen. *J. Am. Chem. Soc.* **53**, 18–30(1931).—In glycolate buffer solns. the reaction $[Co(NH_3)_4CO_3]^+ + 2H^+ + H_2O \rightleftharpoons [Co(NH_3)_4(H_2O)_2]^{+++} + CO_2$ is practically complete; in some acetate buffers it is balanced. "When the CO_2 pressure is low and the H-ion concn. not too small, the velocity may be expressed as the sum of 2 terms, one being independent of the H-ion concn., the other being proportional to the H-ion concn. No general acid catalysis was found." (Cf. Brønsted, *C. A.* **22**, 4334.) Don Brouse

Kinetics of the formation of malonamide from ethyl malonate and ammonia in homogeneous solution. A reaction of the third order. Kenneth C. Bailey. *Proc. Roy. Irish Acad.* **39B**, 567–73(1930).—Although the reaction between $CH_2(CO_2Et)_2$ and NH_3 in homogeneous medium might easily proceed stepwise through the formation of the half amide, it proves to be a true termol. reaction. The reaction was studied in dil. EtOH at 0°, 25° and 33.8°. The resp. values for $k \times 10^3$ are 31.1, 117 and 177. The temp. coeff. is 1.68–1.70. As the concn. of the EtOH is increased, the reaction velocity decreases; thus under the conditions of these expts. the reaction velocity in 76% EtOH was less than 1/6 its value in 44.5% EtOH. The reaction, however, continued termol. An unexpected increase in k was obtained toward the conclusion of the expt. carried out at 33.8° and it is uncertain whether this was due to unrecognized exptl. error or to some accelerating factor developing in the reaction.
C. H. Peet

Pressure-temperature diagrams for definite phase numbers. P. Niggli. *Chem. Zeit.* **5**, 201–24(1931).—Fifty pressure-temp. diagrams are given for 1- to 5-phase systems.
B. C. A.

Theory of arranged mixed phases. Carl Wagner and Walter Schottky. *Z. physik. Chem.*, Abt. B, **11**, 163–210(1930).—Binary systems in which the atoms or mols. are shown by x-ray investigations to be arranged in regular lattice arrangement are designated "arranged" mixed phases, as contrasted with those in which the atoms or mols. are distributed haphazardly. A surplus of one or the other component causes a lattice disturbance. The superfluous atoms may (*1*) occupy an intervening position in the space lattice, (*2*) produce vacancies in the space lattice, or (*3*) occupy a position in the space lattice of the other component. If the component in excess requires less space than the other, position (*1*) is noted; if a larger space, position (*2*) is noted. Where both components require about the same space, as in the case of most intermetallic compds., position (*3*) occurs. The chem. potential and activity, calcd. thermodynamically, det. the relation between the elec. resistance and the compn. The systems Fe–N, Hg–Zn, Au–Hg and Au–Cu are considered.
Curtis L. Wilson

Fusion diagram of the systems mercuric bromide–mercuric sulfate and mercuric chloride–mercuric sulfate. M. Paic. *Compt. rend.* **191**, 1337–9(1930).—By use of a method previously described (*C. A.* **24**, 4208) diagrams are derived for $HgBr_2$–$HgSO_4$. A eutectic mixt. fusing at 236° contg. less than 1% $HgSO_4$ is indicated. The fusion curve mounts rapidly, 506° being the fusion point for 30% $HgSO_4$. From this point values are extrapolated up to the fusion point of $HgSO_4$. The soly. of $HgSO_4$ in fused $HgBr_2$ is less than in $HgBr_2$; the fusion point of a mixt. contg. 10% $HgSO_4$ is 512°.
M. McMahon

System: **chromium–carbon.** A. Westgren and G. Phragmén. *Z. anorg. allgem. Chem.* **187**, 401–3(1930).—The results of Kraiczek and Sauerwald (*C. A.* **24**, [illegible] contradict in certain important respects those previously obtained by the authors (*C. A.* **22**, 2913). The Cr-Cr carbide eutectic is at 3.4% C and not at 4.5%. A cubic carbide of the formula Cr_7C_3 is indicated both by x-ray and micrographic observations in addition to the carbides Cr_4C and Cr_3C_2. There is no series of mixed crystals in the Cr-C interval around 9% C. These discrepancies are attributed to an error on the part of K. and S. in the prepn. of sections for examn.
B. C. A.

The vapor pressure and the activity of a volatile component in binary alloys at high temperatures. Karl Jellinek and Gustav A. Rosner. *Z. physik. Chem.*, Abt. A, **151**, 467–94(1931).—**The vapor pressure of Cd alloys with Pb, Sn and Cu at concns. of 10 to 60% Cd and temps. from 500° to 700° and the vapor pressure of Cu-Zn of the**

concns. from 600° to 800° were measured. The activities of Cd and Zn were calcd. and compared with the electrometric measurements of Taylor. The heat of vaporization and mixing were also calcd. V. F. HARRINGTON

The electrical conductivity and the thermal expansion of magnesium-cadmium alloys. G. GRUBE AND E. SCHIEDT. *Z. anorg. allgem. Chem.* **194,** 190–222(1930).—Investigation of Mg-Cd alloys by thermal analysis does not yield max. or min. points on the solidification curve. An exhaustive systematic investigation of the constitution diagram of the alloys was undertaken by elec. cond. and thermal expansion methods from room temp. to near the m. p. The cond. isotherm of the alloys at 50° shows 3 decided points at 25, 50 and 75% Mg. This confirms the compd. MgCd and proves the previously unknown compds. Mg_3Cd and $MgCd_3$. The 3 compds. are revealed only at lower temps.; $MgCd_3$ results at 89° on cooling the Cd-rich α-mixed crystals sepd. from the melt; Mg_3Cd on cooling the Mg-rich β-mixed crystals to 150°. Cd and $MgCd_3$, as well as $MgCd_3$ and MgCd, form a continuous series of mixed crystals. In comparison, MgCd and Mg_3Cd are only limitedly sol. in one another. At room temp. stable Cd-rich α′-mixed crystals extend from 0 to 65% Mg. Mixed crystals between the concn. boundary of the β′-mixed crystals cannot be accurately detd. but lie in the neighborhood of 60% Mg. The transformation of α′- or β′-mixed crystals into the α or β, stable at high temps., results on heating through heterogeneous double compn. regions whose boundary curve is placed between 20 and 83% Mg. It was shown that in the region of 40–60% Mg and of 70–80% Mg the elec. resistance and the length of the test piece increase with heating, first with a const. temp. coeff. and then in a temp. region of 70–80° below the true transformation interval the temp. coeff. slowly increases. In the transformation interval it increases suddenly and then decreases to a small const. value. The transformation therefore proceeds in 2 steps. The first occurs with the temp. slowly increasing, disarranging the ordered distribution of the atoms, stable at low temps. The second follows the transition of the yet partially ordered into the completely irregular distribution of mixed crystals stable at higher temp. ALLEN S. SMITH

Lattice deformation and catalytic activity. NICOLA PARRAVANO. *Atti III congresso naz. chim. pura applicata* 1930, 45–50.—The behavior of a no. of metals and metallic oxides as catalysts is considered. It is claimed that in some cases catalysis is due to the crystn. of an amorphous powder. It may also be due to a disturbance of the force field around the atoms or mols. by deformation of the crystal lattice. J. B. AUSTIN

The catalytic activity of nickel in the form of aerosol and aerogel. W. E. GIBBS AND H. LIANDER. *Trans. Faraday Soc.* **26,** Pt. II, 656–62(1930). Ni aerosol was prepd. in gas mixts. of CO and H (*1*) by forming an elec. arc between Ni electrodes and (*2*) by thermal decompn. of Ni carbonyl. The aerosol prepd. by these 2 methods showed almost no catalytic activity in the formation of CH_4 from CO and H_2. Ni aerogel was formed (*1*) by the condensation of Ni vapor formed when an arc was struck between a graphite cathode and a Ni ingot anode, (*2*) by the decompn. of Ni carbonyl. These aerogels were used as catalysts in the formation of CH_4 from CO and H_2. They exhibited almost no activity under the same conditions that a Ni + 15% Al_2O_3 catalyst gave about 90% conversion. The Ni aerogel from the arc showed greater activity in the hydrogenation of C_2H_4. Conclusion: Finely divided Ni prepd. by these methods did not produce active catalysts in spite of the large surface formed. L. H. REYERSON

Catalytic experiments with a high-pressure circulation apparatus. E. BERL AND R. BEMMANN. *Z. angew. Chem.* **44,** 34–9(1931). —Water gas was subjected to catalytic high-pressure synthesis in a circulation app. in which the liquid reaction product is sepd. from the gas mixt. A sketch of the app., and details of the design of the high pressure bomb, sepg. vessel, fittings and device for measuring gas velocity are given. The results, in general, confirmed data reported in the literature. Alkali-free ZnO catalyst forms MeOH chiefly. In contrast, higher alcs., acids and aldehydes are formed by the use of an alkali-contg. ZnO. S has an injurious effect on the catalyst. The prepn. and reduction of the catalyst are of great importance. The gas velocity over the catalyst has considerable influence on the reaction. With increasing velocity more unstable intermediate compds. are obtained, while at low velocities the stable end products predominate. ALLEN S. SMITH

The catalytic oxidation of carbon monoxide. J. C. W. FRAZER. *J. Phys. Chem.* **35,** 405–11(1931).—Carefully purified, finely divided MnO_2, Co_2O_3 and Ni_2O_3 are extremely active catalysts for the union of CO and O_2 at temps. as low as 0°. Extreme purity, not the presence of promoters, is important for catalytic activity. Impurities may be removed by electrolysis of an aq. suspension of the oxides. None of 17 other

unnamed oxides studied was effective. The 3 active oxides differ from the others in one significant particular, namely, their compn. is indefinite. By an adsorption app. it was shown that the O_2 pressure in equil. with a sample of one of these oxides depends on the compn. of the oxide. Condensation of water vapor within the pores of these oxides destroys their catalytic activity. Extreme drying does not destroy the activity. These oxides (hopcalite) completely protect a worker when used in a gas mask but they are not yet adapted to the treatment of the exhaust gases of internal-combustion engines. References are made to several dissertations not indexed in chem. literature. F. E. BROWN

Colloidal ferric oxide and various factors that influence its ability to catalyze the decomposition of hydrogen peroxide. I. The temperature coefficient, the effect of catalyst concentration and the effect of electrolytes. RAYMOND J. KEPFER AND JAMES H. WALTON. *J. Phys. Chem.* **35**, 557–77(1931).—Decompn. of H_2O_2 was catalyzed at 50°, in the dark, by chloride-free Fe_2O_3 prepd. in a special high-temp. dialyzer according to Sorum. The reaction seemed to be monomol. The velocity consts. increased as the reaction progressed. The temp. coeff. of the reaction velocity between 30° and 60° was 2.33 for each 10° rise in temp. This indicates that a chem. change, not a diffusion, governed the rate of decompn. The rate of decompn. was multiplied by 2.2 when the concn. of catalyst was doubled between the limits 0.286 and 2.281 g. of Fe per l. When NaCl, $BaCl_2$ and K_2SO_4 were added, the rate of decompn. of H_2O_2 followed typical flocculation curves which show the effects of adsorption of electrolyte on the colloid, flocculation of the sol, and subsequent adsorption on the pptd. Fe_2O_3. When NaH_2PO_4, Na_2HPO_4, HCl, NaOH and $CuSO_4$ were added, similar curves were obtained, but these latter curves were modified by the effect on decompn. of H_2O_2 exerted by the added electrolyte. The activity of this colloidal Fe_2O_3 was about 1000 times the activity of the $FeCl_3$ that it contains. The major catalytic effect is due to Fe_2O_3 and not to $FeCl_3$ as sometimes claimed. It is probable that the formation of higher oxidation products of Fe, such as FeO_2, Fe_2O_5, FeO_3 or H_2FeO_4, is one of the steps in the decompn. of H_2O_2 in the presence of Fe_2O_3. F. E. BROWN

The heat of dilution of salts of several bivalent metals with univalent anions at high dilution at 25°. I. $MgCl_2$, $CaCl_2$, $SrCl_2$, $BaCl_2$ and $MgBr_2$, $CaBr_2$, $SrBr_2$, $BaBr_2$. E. LANGE AND H. STREECK. *Z. physik. Chem.*, Abt. A, **152**, 1–23(1931).—The heats of dilu. for these salts are measured at concns. from 0.1 to 0.0001 *M*. The interpolated value for V_m and m are, at least below 0.01 *M*, in good agreement. The V_m curve is only approx. proportional to $\sqrt{m}$. The extrapolated initial slope agrees with that calcd. by the Debye-Hückel theory. The deviation of m is discussed with respect to the theory, the activity and the osmotic coeffs. and the radius of the unhydrated ions. V. F. HARRINGTON

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

W. ALBERT NOYES, JR.

Connection between the quantum mechanics "uncertainty" and the structure of elementary particles and a calculation of the masses of the proton and electron based thereon. R. FÜRTH. *Z. Physik* **57**, 429–46(1929); *Physik. Z.* **30**, 895–8(1929); cf. *C. A.* **23**, 5405; **24**, 1019.—Theoretical. While the radius of the electron has a definite meaning in the classical electron theory, matters become very complicated on applying quantum mechanics. The Heisenberg "uncertainty" relationship is applied first to a light quantum, and then to protons and electrons. The change of matter into radiation and inversely is considered, and the masses of the electron, proton and neutron are obtained. Eddington's theory of the elementary quantum, in which it is described in 16-dimensional space, is also considered, and the above calcns. are carried out

B. C. A.

Is there dualism between corpuscles and waves? E. SEVIN. *Ann. soc. sci. Bruxelles* **50**, Ser. B, 121–5, 129–34(1930).—S. rejects the explanation of electron diffraction based on the wave mechanics. He assumes (1) that when a beam of electrons of homogeneous velocity v impinges on a crystal the shock produces a "classical" wave, *i. e.*, a beam of parallel x-rays of wave length $\lambda = h\sqrt{1 - (v^2/c^2)}/Mv$. The direction of the x-ray beam is the same as if the incident electron stream were replaced by a beam of x-rays. (2) This "classical" wave immediately entrains the electrons which have just been stopped and only those. The mechanism of the entrainment is identified with the Compton effect. **Reply.** C. MANNEBACK. *Ibid* 125–9.

J. B. AUSTIN

Spectroscopic apparatus in industry. CHARLES C. NITCHIE. *Mech. Eng.* 53, 123–6(1931). E. H.

Canal-ray collisions. CHR. GERTHSEN. *Physik Z.* **31**, 948–53(1930).—The intensity of canal rays can be exactly measured by detg. the ionization in a gas chamber sepd. from the evacuated app. by means of a thin window. Primary currents of 10^{-17} 10^{-20} amp. can still be measured. The laws of canal-ray collisions are as well understood as those of related rays. Several briefly reviewed papers show this. F. L.

The action of Geiger counting chambers. C. BOSCH AND H. KLUMB. *Naturwissenschaften* **18**, 1098(1930).—An investigation was made of the influence of the surface properties of sensitive "points" as used in Geiger counters on disruptive discharges (counter impulses). Geiger-Muller counters used were of the conventional type, cylindrical anode, coaxial filament. The filament could be cleaned by glowing or by ion bombardment. Filaments of Cu, Ag, Au, Fe and Zn were used in He with admixtures of H_2 or O_2. Electronegative admixtures favor the counting effect; pure electrodes and He filling of the tube gave no counting effect whatever, although recovery was noticed after some time. Immersion in liquid air had the same effect of reducing the counting effect. It is concluded that an adsorbed film on the filament has great influence on the counting efficiency, probably a H_2O film. B. J. C. v. D. H.

Characteristic velocity of electrons diffused from metallic surfaces. G. BERNARDINI. *Atti. accad. Lincei* **11**, 1096–9(1930).—There are 3 kinds of secondary electronic emissions: reflected, which do not lose any appreciable velocity; diffused, which lose a little in velocity; secondary electrons, released from the metal reflector and having considerably lower velocity. There are no characteristic velocities to distinguish these classes of electrons, but it has been found recently that at 300–500 v. (Rudberg, *C. A.* **24**, 3431) and also at 150 v. (Brown and Whiddington, *C. A.* **21**, 2221), have noted discontinuities in spectra from secondary emission suggesting inelastic collisions. B working at 34–40 v. and using Cu, Al and Zn reflectors has noted discontinuities with Cu and Zn only. No explanations have been advanced for the phenomena.

A. W. CONTIER.

Electric conduction in metals. W. M. Hicks. *Nature* **126**, 954–5(1930); cf. Fowler, *C. A.* **24**, 3424.—The fact that free electrons in metals do not affect the sp. heat relation as a perfect gas is explainable by their being in the interatomic spaces an insufficient length of time to absorb the energy of the space completely. As they fall into atoms the energy is absorbed by the nucleus, the electrons are distributed in their selected orbits and the energy radiated according to the $nh\nu$ formula. This equalization of energy by the nucleus may explain the behavior of an atom as a perfect sphere and a perfect machine. Gregg M. Evans

Evidence of protons in metals. A. Coehn. *Z. Elektrochem.* **35**, 676–80(1929); cf. *C. A.* **22**, 1904.—Three methods are described to show that electrolytically generated H diffuses through a Pd cathode and thereby imparts to the various points on the electrode the potential which would be assumed by a H electrode. In the first expt. 0.1 N H_2SO_4 soln. was electrolyzed between a Pt and a bent Pd cathode, and after stopping electrolysis the potential at different points on the latter was compared with that of the calomel electrode. At first certain points on the wire showed the O electrode potential as a result of exposure to air, but after 80 hrs. the potential became equal to that of the H electrode. The 2nd method was to observe the variation in elec. resistance of the Pd-wire electrode as a result of the diffusion through it of H. In the 3rd method advantage was taken of the ready oxidation of H contained in Pd by O to form H_2O_2. B. C. A.

The mechanism of spark discharges. J. Slepian. *J. Franklin Inst.* **210**, 473–5 (1930).—Reply to Loeb (*C. A.* **24**, 5611). M. Farnsworth

Infra-red sensitive cells. Fritz Michelssen. *Z. tech. Physik* **11**, 511–5(1930).—The action of photoelec cells sensitive in the infra-red was studied. Cells of Se-Te were prepd. by cathodic evapn. on glass, the film of alloy being extremely thin; the electrical resistance was reduced by prepg. the glass with 2 sets of dovetailed comb-shaped gratings, rubbed in with colloidal graphite and using these as electrodes. The alloy was subsequently deposited on the grating. The distance between the electrode grooves was 0.1 mm., their length 10 mm. The evapn. took place in an A glow discharge. The dark space reached from the Se-Te cathode halfway to the glass plate by proper adjustment of the A pressure. For proper grain size the plate was heated later to 210° for 2 hrs., then enclosed in an evacuated vessel. The light used for the tests on the sensitivity was filtered through proper glass filters which cut off light below 0.745 or 0.675μ. Curves on spectral sensitivity distribution were also made. The data show an active infra-red interval from 0.75μ to 1.2μ for 7 to 13.6 at. % Te in Se. The opinion of Gripenberg (*C. A.* **6**, 449; **7**, 2007) was confirmed on the sensitivity curve toward short λ of plain Se cells when used in a thin film. It is believed that the increased sensitivity of the Se-Te mixt. is due to a changed crystal form of the Se. The case "thallofide" cell was examd. (*C. A.* **14**, 2107). These cells were prepd. by thermal evapn. in O_2 at 0.8 mm. The results were quite satisfactory for practical application of the cells to fog telegraphy. B. J. C. van der Hoeven

A new kind of photoelectric cell. B. Lange. *Physik. Z.* **31**, 964–9(1930).—The new Cu_2O photoelec. cells and their use in photometric measurements are described. Sunlight falling on a cell of this type having a surface of 49 sq. cm. drove a small motor in the Siemens lab. Frank Urban

Remark on the experiment of Rupp on a relation between electron scattering maxima and the emission of soft x-radiation. H. W. B. Skinner. *Naturwissenschaften* **18**, 1097–8(1930).—Recent work of Rupp (*C. A.* **25**, 870) is explainable in a different manner without relating the emission of soft x-rays to crystal structure. Whatever angle of incidence causes a max. reflection of electrons (*i. e.*, a Bragg interference max.) will also cause a min. loss of energy of the electrons to the crystal and thus a max. chance for excitation of the x-rays. Max. x-ray intensity will, therefore, automatically coincide with max. energy scattering of the electrons. **Reply.** E. Rupp. *Ibid.* 1098. B. J. C. van der Hoeven

Determination of atom distances in gas molecules by x-rays and cathode rays. J. M. Bijvoet and H. J. Verweel. *Chem. Weekblad* **27**, 648–50(1930).—A review. B. J. C. v. d. H.

Scattering of electrons by crystals and adsorbed gas films. H. J. Verweel and J. M. Bijvoet. *Chem. Weekblad* **27**, 626–9(1930).—A review. B. J. C. v. d. H.

Energy distribution in continuous Röntgen spectra. K. K. Aglintzev. *Zhur. Prikladnoi Fiziki* **6**, No. 2, 38–46(1929) (Published in *Trans. State Phys.-Tech. Lab.* (Moscow), No. 11(1929)).—A general method for the theoretical detn. of energy distribution is developed analytically (from the current-voltage-time relationship) and graphically (from oscillographs), and applied to inductors and transformers. It is

shown that the exptl. results, after the introduction of necessary corrections, are in agreement with Kulenkampff's (*C. A.* **17**, 1752) law of distribution of energy in Röntgen spectra. B. N. DANILOFF

X-ray investigation of easily deformable crystals. L. CHROBAK. *Bull. intern. acad. polonaise* **1929A**, 497–505.—The technic of obtaining undeformed specimens of easily deformed crystals for x-ray investigations is given. New app. for the work is also described including a simple precision chamber for Laue photographs. B. C. A.

Technic of radiography by γ-rays. CHARLES S. BARRETT, ROY A. GEZELIUS AND ROBERT F. MEHL. *Metals and Alloys* **1**, 872-9(1930).—A technic for taking radiographs by means of γ-rays is given with charts and tables of exposure times for Ra and for Ra emanation. Factors influencing the quality of radiographs and the rapidity of photographic action with γ-rays are discussed. A. J. MONACK

The scattering of hard γ-rays. L. LANDAU. *Naturwissenschaften* **18**, 1112(1930).—It is claimed that Beck (*C. A.* **25**, 871) is in error and that the possible scattering of hard γ-rays by at nuclei is not more than 0.0001 as great as the Compton effect. B. J. C. VAN DER HOEVEN

Theoretical treatment of atomic destruction. GUIDO BECK. *Physik. Z.* **31**, 945–6 (1930); cf. *C. A.* **25**, 248.—An interpretation is given of the problem of collisions between α-particles and nuclei in terms of the quantum theory of aperiodic phenomena FRANK URBAN

Internal conversion of nuclear energy. H. CASIMIR. *Nature* **126**, 953–4(1930).—When a nucleus passes from an excited state to one of less energy, either a γ-quantum is given off or an extra-nuclear electron is emitted with energy equal to the γ-quantum less the ionization energy. This latter is called internal conversion of nuclear energy. The probability of this conversion will be measured by the no. of γ-quanta times a factor K (a function of the frequency). An expression for K is given, based on Dirac's equation. For hard γ-rays such as those from Ra C the electron ejection is mainly nuclear. GREGG M. EVANS

Can lead be rendered radioactive? G. GUÉBEN. *Ann. soc. sci. Bruxelles* 50, Ser. B, 117–21(1930). An attempt was made to detect radioactivity in a series of Pb disks which had been exposed to sunlight, ultra-violet light, x-rays and γ-rays by comparing them with a series of Al disks similarly treated. No activity was observed. Conclusion: Pb is not radioactive and the activity reported by others is probably due to a deposit from the atm. J. B. AUSTIN

The absolute intensities and internal conversion coefficients of the γ-rays of radium B and radium C. C. D. ELLIS AND G. H. ASTON. *Proc. Roy. Soc.* (London) A129, 180–207(1930).—The relative intensities of the γ-rays of Ra B and Ra C and of the photoelec. groups assocd. with them are investigated. In a fraction, α, of the cases the radiation is absorbed in the electronic structure and gives rise to a photoelectron; in the remaining fraction, $1-\alpha$, the γ-ray is emitted clear of the atom. The object of this paper is to describe measurements of the various quantities, α, and on the basis of these results to discuss the question of the mode of energy interchange between the nucleus and electronic system. MARIE FARNSWORTH

The rate of loss of energy by β-particles in passing through matter. E. J. WILLIAMS. *Proc. Roy. Soc.* (London) **A130**, 310–27(1931); cf. *C. A.* **24**, 5219. Exptl. results for the rate of loss of energy by β-particles with velocities from 0.1 to 0.97 c are given. The values for slow electrons are obtained by the cloud method and those for fast electrons in expts. with thin metallic foil. The results have been cor. for the effect of scattering and straggling. The observed values for the rate of loss of energy are 50–80% greater than the theoretical values as calcd. by Bohr and Gaunt using, resp., the old and new quantum mechanics. G. M. MURPHY

The loss of energy by β-particles and its distribution between different kinds of collisions. E. J. WILLIAMS. *Proc. Roy. Soc.* (London) **A130**, 328–46(1931); cf. preceding abstract.—Classical and quantum mechanics indicate approx. the same av. rate of loss of energy by β-particles but the distribution of the energy loss between different kinds of collisions is very different. The results of the quantum theory calcn. agree more closely with expt., particularly in connection with the phenomenon of primary ionization. Quant. agreement is not good for the rate of loss of energy and primary ionization. For collisions in which the energy loss is large and in case of slow electrons, the agreement is within exptl. error. Gaunt's calcns. extended to the case of fast electrons and for non-relativistic quantum theory give a much smaller no. of collisions than expt. This indicates the nature of the relativity correction. G. M. M.

Speculations concerning the α-, β- and γ-rays of radium B, C, C'. I. A revised

theory of the internal absorption coefficient. R. H. FOWLER. *Proc. Roy. Soc.* (London) **A129**, 1–24(1930).—This paper is a math. development of the absorption of γ-rays in a species of photoelec. effect by the planetary electrons of the parent atom, which gives rise to the sharp lines of the β-ray spectrum. MARIE FARNSWORTH

A new method of analysis of groups of α-rays. I. α-Rays from radium C, thorium C and actinium C. ERNEST RUTHERFORD, F. A. B. WARD AND C. E. WYNN-WILLIAMS. *Proc. Roy. Soc.* (London) **A129**, 211–34(1930).—The paper describes some of the applications of the "Greinacher" type of counter for α-rays, in which the ionization current due to a particle is amplified linearly by means of thermionic valves, there being no ionization by collision. By using a double ionization chamber with this type of counter it is possible, in working with complex beams of α-particles, to record only those particles which stop within the chamber itself, and not those which pass right across it, thus giving a measure of the no. of particles having ranges between x mm. and $x + 2$ mm. This differential counter is applied to the study of groups of α-particles emitted from various sources. The 8.6-cm. α-particles from Th C′, the 7.0-cm. particles from Ra C′, and the 3.9-cm. particles from Po all appear to be homogeneous groups. The 5.5-cm. particles from Act C are found to consist of 2 well-marked groups, differing in range by 4.2 cm. The 4.8-cm. particles from Th C form also a complex group, in agreement with the results of Rosenblum, who showed that they consisted of at least 5 groups of particles. The missing short-range α-particles emitted in the dual disintegration of Ra C are found and their consts. detd. It is found that these α-particles are present to an extent of about 1 in 4,000 of the main 7.0-cm. particles from Ra C′; they appear to consist of 2 groups—the main one of range 4.1 cm. and a smaller one of range 3.9 cm. MARIE FARNSWORTH

α-Particles of the actinium series. PAOLO MISCIATTELLI. *Atti III congresso naz. chim. pura applicata* **1930**, 388–94.—M. has studied the range of α-particles emitted by radioactinium and actinium X as a function of the time elapsed since their prepn. The results are interpreted to show the appearance of various decompn. products. J. B. AUSTIN

An assumed transformation of lead. Remarks on the notes of Smits, Boutaric and Lepape. STEPHANIE MARACINEANU. *Bull. sect. sci. acad. roumaine* **13**, 55–8(1930); cf. 24, 204, 2950, 3427, 4454, 4699.—S., B. and L. confirm the radioactivity of ancient Pb coverings, but consider the cause of the radioactivity debatable. M. presents arguments in favor of solar action. H. W. WALKER

Experiments to discover a stable isotope of polonium. G. v. HEVESY AND A. GEIGNER. *Z. anorg. allgem. Chem.* **194**, 162–78(1930).—Of the elements of the radioactive decompn. series, only elements 81, 82 and 83 have stable, as well as radioactive, isotopes. In order to discover a possible stable Po isotope, large quantities of the Te minerals, hessite, calaverite, nagyagite, and the Bi minerals, Bi telluride, bismuthinite, and metallic Bi were used with Po as an indicator. The Po was added to the soln. of the mineral and at the end of the expt. was again sepd. A possible present stable Po isotope would sep. with the Po. It is pointed out that the Po ppt. weighed only about 0.1 mg. and contained less than 1% of the element sought as detd. by x-ray spectroscopic investigation. It is concluded that the minerals investigated did not contain the element sought, or contained less than 10^{-11} g. per g. of mineral. Methods were worked out for the chem. and electrolytic sepn. of Po from large amts. of foreign substances especially Te and Bi. A systematic investigation of the electrolytic sepn. of the different metals gave the most favorable results with the use of Mo as the cathode. ALLEN S. SMITH

The isotopic constitution and atomic weights of zinc, tin, chromium and molybdenum F. W. ASTON. *Proc. Roy. Soc.* (London) **A130**, 302–10(1931).—Expts. with Cd and Ge were unsuccessful. The following figures give the mass no. and percentage abundance of the isotopes, the isotopic moment, mean mass no., at. wt. and packing fraction, resp.: *Zn:* 64, 48.0; 65, 2.5; 66, 25.9; 67, 5.3; 68, 17.1; 69, 0.85; 70, 0.58, 1.41; 65.452; 65.380 ± 0.02; —9.9. *Sn:* 112, 1.07; 114, 0.74; 115, 0.44; 116, 14.19; 117, 9.81; 118, 21.48; 119, 11.02; 120, 27.04; 121, 2.96; 122, 5.03; 124, 1.77; 118.82; 118.72 ± 0.03; —7.3. *Cr:* 50, 4.9; 52, 81.6; 53, 10.4; 54, 3.1; 0.31; 52.068; 52.011 ± 0.006; —10 ± 3. *Mo:* 92, 14.2; 94, 10.0; 95, 15.5; 96, 17.8, 97, 9.6; 98, 23.0; 100, 9.8; 1.87; 96.025; 95.97 ± 0.06; —5.5. These results include correction of the order of abundance for Zn and Sn and the discovery of 3 new isotopes of Cr and 7 of Mo. G. M. MURPHY

The radioactive properties of rocks, soils, crude oil and waters from Southern California. J. LLOYD BOHN. *J. Franklin Inst.* **210**, 461–72(1930); cf. *C. A.* **24**, 4699.—This paper contains measurements on waters from Lake Arrowhead, Arrowhead

Hot Springs, Harlem Hot Springs, the Pacific Ocean and from numerous wells and tunnels of the Pasadena and neighboring water supplies. It also contains measurements on rocks, soils and crude oil. MARIE FARNSWORTH

Nature and size of the luminescent center. J. EWLES. *Proc. Roy. Soc.* (London) **A129**, 509–19(1930).—By reasoning in accord with recent knowledge of luminescent solid solns., and free from the doubtful assumptions used by Merritt, an equation relating brightness of luminescence and concn. of activator has been derived. This expression is similar to that of Brüninghaus. It was found to apply to solid solns. Sb_2O_3, Bi_2O_3 and PbO each in CaO, to uranin and Rhodamine 6G in water, and to fluorescein in EtOH. FRANK URBAN

The scattering of slow α-particles by helium. P. M. S. BLACKETT AND F. C. CHAMPION. *Proc. Roy. Soc.* (London) **A130**, 380–8(1931).—The scattering of particles by an inverse-square law is the same in classical and quantum mechanics. Mott (*C. A.* **24**, 2040) by means of wave mechanics has shown the scattering to be quite different from the classical when the scattered and scattering particles are of the same kind. The scattering of α-particles by He is a case of collision of particles of the same kind that have no spin and obey the Einstein-Bose statistics. Photographs of 50,000 α-rays from Po were made with the Wilson cloud method in He-O_2 mixt. The results agree with Mott's theory. G. M. MURPHY

Recoil atoms in a gaseous medium. LA. GOLDSTEIN. *Compt. rend.* **191**, 145–7 (1930).—It has been shown previously that the degree of activation of a negatively charged electrode immersed in a mixt. of radon and air varies with the pressure of the mixt. At low pressures the degree of activation is very feeble, because the high velocities of the recoil atoms, Ra A and Ra B, are not slowed down by the low gas pressure sufficiently for them to be diverted to the charged electrode. As the pressure increases the degree of activation of the electrode increases to a max. because the path of the recoil atoms is shortened by the increased gas pressure. Then, after passing through a max., the degree of activation of the electrode decreases as the pressure of the gas mixt. increases. In the present paper expts. are described in support of the following hypothesis regarding this decrease. As the pressure increases, the ionization of the gas increases in consequence of the better utilization of the paths of the α-rays, and the decrease in degree of activation is due to the recombination of the positively charged recoil atoms with the negatively charged ions of the gas. It is further shown that the degree of activation of an anode increases constantly with the pressure of the gas, under the same conditions that cause the degree of activation of a cathode to pass through a max. and then decrease. Also, that increase of the ionic density does not sensibly decrease the degree of activation of an anode. Expts. designed to explain this behavior of the anode are in progress. R. H. LOMP

Space distribution of *H*-particles liberated from aluminum by α-rays of polonium. H. POSE. *Physik. Z.* **31**, 943–5(1930).—Absorption curves of *H*-particles ejected from Al by Po α-rays were detd. for the angles of 48°, 65°, 105° and 135° between primary and secondary rays. Excellent agreement was found with values calcd. by the method of Bothe. FRANK URBAN

Absolute intensity of the aurora line in the night sky and the number of atomic transitions required to maintain it. LORD RAYLEIGH. *Proc. Roy. Soc.* (London) A129, 458–67(1930).—The standard instrument used in measuring the green auroral light of the night sky was calibrated. If the transmitted light is assumed to consist entirely of λ5577, the brightness corresponding to the zero reading of the instrument was found to be 8.65×10^{-8} candles/sq. m. Deducting the fraction attributable to the continuous background, the brightness of the line becomes 3.2×10^{-8} candles/sq. m. The energy required to maintain it is 6.4 ergs/sec./sq. m. and the no. of at. transitions required to supply the energy is 1.81×10^{12}/sec./sq. m. FRANK URBAN

Change in electron coupling in the rare gases. C. J. BAKKER. *Naturw.* 126, 955; *Naturwissenschaften* **18**, 1100(1930).—*g* values for *SL* and *JJ* couplings for $^3P_2$ and $^3P_1$ levels are given for Ne I, A I, Kr I and Xe I. The agreement is good except in Xe I, where first-order calcns. are probably not sufficiently accurate for large values of spin orbit reaction. GREGG M. [illegible]

Interferometric measurements in the arc spectrum of iron. C. V. JACKSON. *Proc. Roy. Soc.* (London) **A130**, 395–410(1931).—Interferometric measurements were made of 10 lines in the Fe arc spectrum between 4000 and 4400 A. U., by comparison with the red Cd line and the secondary Ne standards. Measurements have also been made of 68 lines between 2300 and 3100 A. U. in the Fe arc and 5 lines in Hg from 2652–2920 A. U. The results are in good agreement with other investigators and with calcd. results obtained from energy levels. G. M. MURPHY

Apparatus for determining optical and magnetic rotatory dispersion in the ultra-violet. AUGUST HAGENBACH. *Helv. Phys. Acta* **3**, 168–79(1930). EGON BRETSCHER

The effect of crossed electric and magnetic fields on the Balmer lines of hydrogen. WALTER STEUBING. *Naturwissenschaften* **18**, 1098–9(1930).—Preliminary results are given. The effect was not the appearance of new lines but consisted of a shift of the Stark-effect components and intensity changes. Weak magnetic fields do not influence the intensity distribution materially; strong fields suppress all Stark-effect components. B. J. C. VAN DER HOEVEN

Bergmann series in the argon spectrum. EBBE RASMUSSEN. *Naturwissenschaften* **18**, 1112 3(1930).—Until now Bergmann series were only known for Xe (Meggers, de Bruin, Humphreys, *C. A.* **24**, 1287). Similar series have now been found in A by using a plane grating and neocyanine plates and an A tube at 2 mm. pressure. The results are given in tables, including derived values for the terms $3d_6$ to $3d_3$ and $3d_2$ to $2s_5$ and $3s''$. B. J. C. VAN DER HOEVEN

The fluorescence of excited mercury atoms. Z. ZAJAC. *Compt. rend.* **191**, 1304–6 (1930).—Hg vapor in a sealed tube was simultaneously subjected to an oscillating elec. discharge and to an intense, low-pressure Hg-vapor arc. External electrodes were used. A greenish blue luminous color was observed in the pos. column limited by the contour of the exciting rays. It started at a pressure of 0.05 mm. and attained its max. intensity at 0.3 mm. and at a temp. of 140°. At 1 mm. a continuous intense spectrum excited by the discharges was observed which masked the fluorescent light so that it was no longer visible at pressures above 1.5 mm. Raising the temp. of the vapor at const. pressure does not noticeably influence the phenomenon. Photographing the spectrum gives the 5461, 4358 and 4047 Hg lines, which are intensified by the simultaneous excitation. Each of the 3 lines is capable of causing the fluorescence, but with different degrees of intensity. The yellow lines 5790 and 5769 do not cause it. The intensities of all lines seen during the fluorescence are proportional to the intensity of the exciting light. F. W. LAIRD

Analysis of the ultra-violet hydrochloric acid bands. M. KULP. *Physik. Z.* **21**, 9–10(1930), cf. *C. A.* **24**, 5228.—The bands between 3000 A. U. and 4000 A. U. have been rephotographed and analyzed. FRANK URBAN

New band group in the ultra-violet absorption spectrum of selenium vapor. (MLLE.) M. STORCZEWSKA. *Bull. intern. acad. polonaise*, **1930A**, 17–9.—A new band group has been observed in the absorption spectrum of Se vapor in the spectral region 2100–2 [illegible] A. U. Like other Se bands they are degraded toward the red, but unlike the other Se band series no rotational fine structure could be detected with the dispersion employed. The frequencies of 12 band heads have been measured and are expressed by the formula $\nu = 43{,}210 + 368n - 0.2n^2$. Since the bands appear in the satd. Se vapor at relatively low temp., 200° ($p = 0.001$ mm.) to 400° ($p = 4$ mm.), and since the mean frequency difference is 363 cm.$^{-1}$ as against 200–250 cm.$^{-1}$ for the bands in the visible region, it is suggested either that the carrier of this spectrum is not Se_2' but a [illegible] Se mol., or, more probably, that this spectrum corresponds with a different electron jump from that corresponding with the bands previously observed. B. C. A.

Spectroscopic observations of photochemical reactions. R. MECKE. *Z. wiss.* [illegible] (Schaum Festschrift) **29**, 72–6(1930).—Photochem. reactions which are in agreement with Einstein's equivalence law can be regarded as single reactions. Those reactions which do not follow the equivalence law may be regarded as being chain reactions. A. P. H. TRIVELLI

The chemical effects of cathode rays. I. The decomposition of ammonia. G. R. PAINE AND T. E. ALLIBONE. *Proc. Roy. Soc.* (London) **A130**, 346–66(1931).—A beam of electrons from a Lenard tube with 240 kv. and currents up to 4 microamp. was passed through Al foil into NH_3. The decompn. products are N_2H_4, N_2 and H_2. From 5.75 to 1 cm. initial gas pressure, the rate of formation of permanent gas is approx. proportional to the pressure and independent of the nature of the surface. The relative yield of N_2H_4 is greater at low pressures for the same relative amt. of decompn. A manometer is described for the measurement of the energy of the electrons entering the reaction vessel. It gives results for the amt. of energy reacting per mol. of the same order of precision as may be obtained with α-particles. The results are in good agreement with those obtained in the same reaction with α-particles and agree qualitatively with decompn. in the silent discharge and in ultra-violet light. For each ion-pair formed, 1.2 mols. of NH_3 are decomposed. G. M. MURPHY

Sorption and chemical reactions in atomic rays. M. LANCUCKI. *Bull. intern. acad. polonaise* **1930A**, 20–9.—A study has been made of the close relationship which

exists between the absorption of N in an elec. discharge tube, Fe or Al electrodes being used, and the disintegration of these metals. The amts. of N absorbed and of Fe disintegrated are equiatomic and depend on the gas pressure, the cathode fall, the c. d., and the temp. of the cathode. If the cathode is constructed of Fe nitride, the latter is disintegrated without absorption of N. The Fe nitride formed by this process is not ferromagnetic. B. C. A.

The action of electrical discharge on gaseous hydrocarbons. The effect of high-speed cathode rays on paraffin hydrocarbons. S. C. Lind, B. M. Marks and G. Glockler. *Trans. Am. Electrochem. Soc.* 59 (preprint) 8 pp.(1931).—It has been found that the hydrocarbons methane, ethane, propane and butane are decomposed by the high-speed electrons (125,000 v.) which are emitted through the thin glass window of a Slack-Lenard cathode-ray tube. H is one of the products of decompn. An estimate is made of the no. of mols. reacting per electron crossing the reaction tube and of the no of ion pairs produced in the reacting gas per electron traversing it. The comparison of these ratios shows that the no. of mols. reacting and the no. of ions pairs formed are of the same order of magnitude. C. G. F.

Physical methods in the chemical laboratory. XVI. The effect of electrical discharges on gaseous elements and compounds. H. Gehlen. *Z. angew. Chem.* **44,** 30-4 (1931).—The formation of active N and H, the synthesis of acetylene, the polymerization of benzene, and the decompn. of thiocyanic acid and carbonic acid in the elec discharge are reviewed. Methods and app. are discussed. Chem. reactions of the active substances as reported by numerous investigators are summarized with an extensive bibliography. Allen S. Smith

The dielectric constant and the conductivity of ionized gases. Th. V. Jonescu and C. Mihul. *Compt. rend* **191,** 1436-8(1930). The gas was ionized by a current of electrons in a glass tube provided at one end with a W filament, at 4 mm. from this with a grid, at 7 cm. a Cu ring, and at 17 cm. an Al plate. When the ring and plate were at the same potential, ΔC and $1/\rho$ were proportional to the electron current, ΔC being the change in capacity due to the change in dielec. const, and $1/\rho$ the cond. of the gas. If λ is the wave length supplied by the oscillator, and if the results are reduced to a current of 1 milliamp., then C/λ^2 is neg. for wave lengths between 2 and 12 m., and then becomes pos. C/λ^2 is independent of the value of the accelerating potential. The wave length for which C/λ^2 changes sign is independent of the intensity of the current between 0 and 2 ma. The conductance, $1/\rho\lambda^2$ is proportional to the intensity of the ionization. Its variation with λ is less simple. For an accelerating potential of 400 v it has maxima at λ = 2.4 m., and 6 m.; and a min. at 3.3 m. For greater wave lengths it decreases rapidly and approaches 0 for $\lambda = \infty$. For 1600 v. $1/\rho\lambda^2$ remains const up to 6 m., and then approaches 0 rapidly as λ increases. R. H. Lombard

The hypothetical existence of Hertzian frequency resonators in water. P. Girard and P. Abadie. *Compt rend.* **191,** 1300-2(1930).—The dielec. consts of distd. water obtained by using wave lengths ranging from 49.13 to 63.56 cm. are recorded together with the dielectric consts. of 1.5×10^{-4} *N* Na_2SiO_3 at 10° for wave lengths ranging from 50.18 to 60.28 cm. The dispersion bands noticed by Weichmann and Frankenberger were not obtained in this region. The hypothesis for the existence of Hertzian resonators of a new type is found untenable because of the lack of confirmation of exptl. data. F. W. Laird

Excitation of fluorescence in benzene at —183° by monochromatic light. J. Starkiewicz. *Bull. intern. acad. polonaise* **1929A,** 287-94; cf. Pringsheim and Reimann, *C. A.* **19,** 439; Pringsheim, *C. A.* **21,** 1059.—The fluorescence spectra excited in C_6H_6 at —183° by the almost monochromatic radiation from electrodes of Zn (λ = 2502 and 2558 A. U.) and of Cd (λ = 2265 and 2313 A. U.) are in all respects similar to each other and to that obtained in similar circumstances by Reimann with a Hg lamp. This independence of fluorescence of wave length is due not as in the case of the vapor, to collisions, but, as supposed by Pringsheim, to some intramol. mechanism. B. C. A.

The influence of the wave length of the exciting rays on the fluorescence spectrum of etioporphyrin. The structure of this spectrum in the infra-red and ultra-violet. J. Aharoni and Ch. Dhéré. *Compt. rend.* **190,** 1499-1501(1930); cf. *Compt. rend.* **183,** 321(1926).—With the wave length of the exciting rays varying from 365-546 mμ there were no noticeable variations in the no., position or intensity of bands in the fluorescence spectrum of etioporphyrin. T. H. Rider

Spectrophotometric study of the cupric-pyridine ion in aqueous solution. Aumeras and Tamisier. *Compt. rend.* **191,** 99-100(1930).—The absorption curves for various mixts. of $Cu(NO_3)_2$ and pyridine were detd. There is a max. in the curve, corresponding

to 20% $Cu(NO_3)_2$, showing the existence of $[Cu(C_5H_5N)_4](NO_3)_2$. The stability const. for the deep blue complex ion is 3.1×10^{-4} at 18°. E. G. VANDEN BOSCHE

The photoelastic dispersion of vitreous silica. L. N. G. FILON AND F. C. HARRIS. *Proc. Roy. Soc.* (London) **A130**, 410–31(1931).—The dispersion of the double refraction produced by stress has been accurately investigated with 2 blocks of vitreous silica. Results have been obtained for 23 standard Fe lines between 4602 and 6495 A. U. Values are given for the stress-optical coeff. at 6 different loads from 10 to 40 kg. The photoelastic dispersion curve shows anomalous dispersion. This may be due to natural periods of Si, as some of the irrregularities in the curve correspond to lines in the Si spectrum. G. M. MURPHY

Is the blackening and blanching of exposed lithopone a photographic phenomenon. H. STOBBE. *Z. wiss. Phot.* (Schaum Festschrift) **29**, 209–18(1930).—An investigation is made of the light and dark reaction of ZnS and lithopone under different conditions. Phototropism is termed a photochem. reaction in which, by light exposure, a solid acquires a darker color which disappears again in the dark. S compared the behavior of lithopone in light and dark with well-known photographic reactions and found differences which show that lithopone is not a photographic substance. A. P. H. T.

Behavior of dispersed systems in filtered ultra-violet light. KARL BORGMANN. *Suddeut. Apoth.-Ztg.* **71**, 70–2(1931).—A general discussion. W. O. E.

Industrial electric heating. J. I. BERNARD. *Elec. Eng. Australia and New Zealand* **7**, 365–8(1931).—A review. C. G. F.

The production of high-manganese slag in the electric furnace. T. L. JOSEPH, C. E. WOOD AND E. P. BARRETT. Bur. Mines, *Rept. of Investigations* **3080**, 9 pp.(1931). Elec. furnace tests made with 150-lb. charges of spiegel, contg. about 15% Mn and 0.5% P, indicate that 2 types of high-Mn slag may be produced from metal of this type. When SiO_2 was used as a thinning agent, the slag had an av. compn. of MnO 68.1,

FeO 5.2, SiO_2 14.3, P 0.11 and Al_2O_3 8.2%. With the exception of frothy slags, Al_2O_3 worked as well as SiO_2 as a thinning agent, the resulting slag being of the following av compn.: MnO 69.6, FeO 6.1, SiO_2 8.7, P 0.16 and Al_2O_3 13.0%. The SiO_2 and Al_2O_3 may b varied over a wide range provided their sum is about 22% of the slag. A continuous cycl gave better results than a batch operation. From 85 to 90% of the Mn could be r covered in the slag, 3–6% in the metal, and 6–8% was lost. More strongly reducing con ditions can be established in the elec. furnace than in the open-hearth, more positiv control of P and Fe in the slag being thus permitted and the treatment being reduced to about 1/2. ALDEN H. EMERY

The coreless induction furnace in a new role. A. G ROBIETTE. *Iron and Ste Ind. and British Foundryman* 4, 125–9(1931); cf. *C. A.* 24, 5638.—Expts. were mad to det. the possibilities of refining low-grade steel scrap of various compns. and po irons, the extent of the elimination of the elements Si, Mn, P, C and S under varying conditions, and the speed of their elimination. Si is removed as rapidly as ore is charged P elimination is rapid and complete under suitable slag conditions. C removal is rapi in both the slag reaction process and the air-blast method. S removal is general erratic; it increases with the CaF_2 addn. Products of deoxidation are removed in few sec through rapid circulatory motion of the charge. An auxiliary arc above th slag surface to keep it fluid is suggested. C. H. LORIG

Hydrometallurgy of copper at the Bagdad property. CHARLES T. BAROCH *Trans Am. Electrochem. Soc.* 57, 205–29(1930).—The ore minerals are principally chalcopyr te and chalcocite. Cu in the ore averages 1 to 1.25%. After roasting the ore it was leached with spent sulfate electr dyte, Cu extns as high as 91% resulting. The soln. builds up in Cu to a concn. of 60 g./l. and more, the free H_2SO_4 dropping to 1 g./l. By diverting part of the spent electrolyte into this soln. coming from the leach plant, the Cu is brought down to 50 g./l. and the acid up to 25 g./l., an electro of good elec. cond. resulting. The c. d. of the Cu cells is 2.1 amp./sq. dm. (voltage has ranged from 1.97 to 2.12 v. C. G.

The electrolytic zinc plant of the Evans-Wallower Company at East St. Louis, Ill U. C. TAINTON AND DANIEL BOSQUI. *Trans Am. Electrochem. Soc.* 57, 241–53(1930). The Joplin district will probably continue for many years to be the chief Zn-producing district of the U. S. Hitherto, all Zn from this field has been produced by the old process of retort smelting. The paper describes the first plant to treat these ores electrolytically. Flotation concentrates are roasted in Wedge furnaces, the roaster gas being converted to H_2SO_4 by the contact process. After passing over magnetic separators the concs. are leached in spent electrolyte (28% H_2SO_4). The heat of the reaction raises the temp. to the b. p. Residues contg. Pb, Ag and Au are shipped to the Pb smelter. Leached soln. is purified with Zn dust to ppt. Cu, Cd, Co and Ni. The Cd is sepd. from the Cu and recovered electrolytically, while the Cu goes to a Cu smelter. In the Zn cells, Al cathodes are used at a c. d. of 10.7 amp./sq. dm. Anodes are in grid form and are composed of Pb alloy contg. 1% Ag. During electrolysis MnO_2 is pptd., a high-grade product free from Fe, Cu, Ni, etc., being the result. The electrolytic Zn produced is 99.99% pure. The daily capacity of the plant is 50 tons of electrolytic Zn and 1/2 ton of Cd. C. G. P.

Germanium in relation to electrolytic zinc production. U. C. TAINTON AND E. P. CLAYTON. *Trans. Am Electrochem Soc* 57, 279–88(1930); *Metal Ind.* (London) 37, 229–30, 326(1930).—Certain impurities in the Zn soln., if not removed, will deposit with the Zn and lower the overvoltage below the critical point. In the "high acid, high-density" process, Sb, Co, Ni and As, which are objectionable impurities, are readily removed. However, a hitherto unsuspected impurity which gave rise to low current efficiencies was, after careful investigation, found to be Ge. Concns. as low as 1 mg./l. are sufficient to cause serious losses in Zn cathode efficiency. Ge may be adsorbed and removed from soln. by means of $Fe(OH)_3$ pptd. by ZnO in the leaching operation. C. G. P.

The cathode precipitate as a function of exterior factors in solution of zinc sulfate. A. GLAZUNOV AND K. RÖSNER. *Chem. Obzor* 5, 221–3, 253–63(263 English)(1930). The theoretical conditions of Zn pptn. from $ZnSO_4$ soln. and the influence of various factors were investigated. High c. d., low temp., low H-ion concn. and the presence of clay particles were favorable for the formation of a smooth and thin deposit. The concn. change from 25 to 110 g./l. Zn has practically no influence on the type of the deposit. The expts. are elucidated by numerous diagrams. F. KUČERA

Some experiments on the electrodeposition of gold from alkaline cyanide solutions. E. T. DUNSTAN. *J. Chem. Met. Mining Soc. S. Africa* 31, 118–27(1930).—No evidence of regeneration of cyanide by electrolysis of a working cyanide soln. was found; in fact,

a further loss occurred. The use of a rotating cathode does not materially increase the current efficiency, which is extremely low, because of the dil. solns. employed. Electrolytic methods cannot economically improve upon Zn pptn. It is doubtful if space and power would be saved, as the soln. required 4 passes through the cell. The rotating cathode has a depolarizing effect, probably because the friction of the soln. keeps the surface free from bubbles of gas, which enables a lower voltage and higher c. d. to be employed. Also in *Metal Ind.* (London) **38**, 295–7(1931). ALDEN H. EMERY

A new abnormality in the properties of aqueous solutions of cadmium salts. ELMER JESCHE AND PIERRE J. VAN RYSSELBERGHE. *Trans. Electrochem. Soc.* 59 (preprint) 7 pp. (1931).—Electrolysis of aq. solns. of CdI_2 yields cathode deposits contg. a large amt. of adsorbed CdI_2. $CdBr_2$ behaves in the same way, while $CdCl_2$ yields normal deposits of pure Cd. The phenomenon is ascribed to the adsorption of neutral mols. An explanation for the difference of behavior of the iodide and the bromide on one hand, and of the chloride on the other hand, is suggested. C. G. F.

Cadmium as a rust preventive. BERNHARD PLANNER. *Z. Elektrochem.* **37**, 33–49 (1931); cf. *C. A.* **24**, 2059.—Cd is successfully deposited from an alk. cyanide bath at 40–60° and at current densities of 50–150 amp. per sq. m., with or without the addn. of colloids. In acid baths conditions must be carefully controlled. With increasing temp. and c. d., the current efficiency increases but the grain size of the deposit also increases. The best results are obtained at 40° with a c. d. of 100–150 amps. Acid baths are non poisonous, and in them there is no decompn. of the anion. With increasing mol. wt. of the electrolyte the grain size of the Cd deposit falls. This is greatest in H_2SO_4 solns. and smallest in phenolsulfonic acid solns. Bright deposits can be obtained from fluosilicic and phenolsulfonic acid baths with added colloidal material, but such deposits are quite brittle and show poor adherence to the ground metal. H. S.

Addition agents in bismuth electrolytes. EDWARD F. KERN AND THOMAS R. JOSEPH. *Trans. Am. Electrochem. Soc.* **57**, 255–72(1930).—Solns. of fluosilicate, fluoborate, cresol sulfonate, perchlorate, fluoride, sulfate and chlorides were tested for electrolytes of Bi, the result being the selection of $BiCl_3$ solns. contg. NaCl, $CaCl_2$ or $MgCl_2$ as the most suitable electrolytes. The addn. agents tried were glue, goulac (sulfite liquors) gum arabic, tannin, aloin, aloes curacoa, hydroquinone, benzoic acid, pyragallol and resorcinol. Pyragallol and resorcinol added to the electrolytes produced the brightest and densest deposits of Bi; hydroquinone was next in order, benzoic acid next, and the other addn. agents were not beneficial. C. G. F.

High-speed nickel plating as practiced in England. ERNEST R. CANNING. *Trans. Electrochem. Soc* **59** (preprint) 4 pp. (1931).—In England current densities of 2.2 amp./sq. dm. and over are used. Continuous filtration of the electrolyte, kept at 32° to 35°, is necessary to eliminate suspended foreign matter and pinholes. Because of considerable loss in throwing power, C. advises against very high current densities. The preferred p_H is 5.6 to 5.8. The cathode efficiency is 96 to 97%. A plate 0.025 mm. thick is obtained in 45 min. with a variation in thickness of not more than 45%. For adequate protection of the steel, a Ni plate of at least 0.025 mm. is necessary. For subtropical countries composite deposits of Ni-Cu-Ni are recommended. C. G. F.

Chromium plating. E. J. DOBBS. *J. Soc. Chem. Ind.* **49**, 161–5T; *Metal Ind.* (London) **36**, 435–6, 459–60(1931).—A brief history of modern practice. The tendency in the U. S. is to aim solely at cond. and to overcome the disabilities attendant in high concentration on the outstanding points of a recessed article, by the use of auxiliary cathodes or "robbers." In England research has been centered on increased "throwing power" without auxiliary cathodes or the use of specially shaped anodes. In England flat lead anodes are used. For articles subjected to atm. conditions a thick undercoat of Cu is essential. It is well to have the plating vats lined with hard Pb. This obviates any possibility of the continued formation of $Cr_2(CrO_4)_3$ and yet cannot cause any burning of the work from too large an anode surface, because of the screening action of the glass lining fitted to the latest types of vats to protect the Pb from mech. injury. The matters of temp., c. d., and prepn. of the articles for Cr plating and the stripping of Cr deposits are discussed. W. H. BOYNTON

Variations in the electromotive force during the formation of alloys by the wet method. E. PACE. *Gazz. chim. ital.* **60**, 811–8(1930).—In connection with studies of Marchelli on the formation of binary metal alloys by the wet method, the phenomenon was examd. from the electrochem. point of view. Similar expts. have been carried out by Tammann but under different conditions and with a different object (cf. *C. A.* **14**, 671). The present paper deals with variations in the e. m. f. of the voltaic combination $A \mid A^+$ soln. $\mid B$, during the entire transformation in the following systems: Cu–Sb, Sb–Sn, Au–Cd, Ag–Cd, Au–Sn and Ag–Sn. A high initial e. m. f

would be expected because of the difference between the 2 potentials A | A^+ soln., and B | A^+ soln., where the first remains const. throughout and the 2nd is electrochemically indefinite as a result of the nominal absence of B^+ ions and theoretically is infinite. Practically, however, the 2nd has a definite value either because of soln. of traces of B (by the action of atm. O or by double decompn. with A^+ cations), or, in case the B electrode is completely passive, because of the oxidizing potential which it acquires in contact with the soln. The app. is described in detail. In the *Cu–Sn system*, during the formation of Cu_3Sn (cf. *Ber.* **27**, 630(1897)) the e. m. f. at 100° was initially 0.131, and this rose slowly to a max. of 0.214. In the *Sb–Sn system*, the e. m. f. at ordinary temp. with open circuit varied from 0.31 to 0.33, while with a closed circuit it diminished gradually to a min. value of 0.80 after several hrs., and this again increased to 0.300 when the circuit was opened. In the *Au–Cd system*, the e. m. f. at ordinary temp. was 0.73 and at 100° was 0.77, and this diminished rapidly with the circuit closed until it reached 0.12 after 1 hr. at ordinary temp. and 0.013 after 20 hrs., while at 100° it diminished to 0.96 after only 15 min. In the *Ag–Cd system*, the initial e. m. f. at ordinary temp. was 0.67, and this increased slowly to a max. of 0.73. With the couple in a closed circuit at ordinary temp., the e. m. f. diminished slowly from 0.72 to 0.42 after about 30 min. and reached 0.01 after 2 hrs. In the *Au–Sn system* at ordinary temp., the initial e. m. f. was 0.39 and diminished only to 0.37 after 6 hrs., while with the circuit closed it diminished from 0.37 to 0.05 after 20 min. When the temp. was increased to 100°, a closed circuit for only 3 min. was sufficient to reduce the e. m. f. from 0.36 to 0.05. In the *Ag–Sn system* at ordinary temp., the e. m. f. was approx. 0.35, and with the couple in a closed circuit this diminished to 0.01 after only 2 min. At 100° the behavior was substantially the same, except that the changes were accelerated. C. C. Davis

Electrodeposition of cobalt-nickel alloys. II. S. Glasstone and J. C. Speakman *Trans. Faraday Soc.* **27**, 29–35(1931).—The investigations of the compn. of alloys deposited from mixed buffered solns. of Co and Ni sulfates under various conditions reported previously (*C. A.* **25**, 459) have been extended to higher temps., approx. 50° and 90°. In the present work it has been found that the variation with increasing c. d. of the compn. of the Co-Ni alloys is very different at high and at low temps. At 15° the compn. of the alloy is almost independent of c. d. until the rate of removal of ions from soln. by electrodeposition exceeds the rate of diffusion of these ions to the electrode; at 50° the proportion of Co increases rapidly with increasing c. d. before a const. compn. is reached (cf. *C. A.* **21**, 3025; **22**, 3588). The exptl. conditions in the present work were as reported in Part I, and graphs of the atomic % of Co plotted against c. d. in amps./sq. dm. are given. The relative tendency for Co and Ni to deposit is independent of the H-ion concn. of the electrolyte. The alloys deposited at very low c. ds. contain decreasing proportions of Co as the temp. is raised, this proportion is, in general, less than that in the soln. for depositions made at 90°. With increasing c. d. the fraction of Co in the alloy increases rapidly until a max. Co content, independent of c. d., is attained; this max. decreases with increased temp. The influence of Co on the deposition of Ni at 50° and 90° is very similar to that of Fe at 15° and 50°, resp. In general, the current efficiency increases, for the reason that the deposition potential decreases more rapidly than the H overvoltage, with increasing temp. The theoretical basis of the results is discussed in terms of the deposition potentials and overvoltages of the metals concerned. Edward B. Sanigar

Polarographic studies with the dropping-mercury cathode. XV. Positive and negative maxima on current-voltage curves. J. Heyrovský and M. Dillinger *Collection Czechoslov. Chem. Comm.* **2**, 626–38(1930).—The anomalies observable on electrocapillary curves obtained by the drop-wt. method have been shown (*C. A.* **24**, 2675) to be indicated on the current-voltage curves by prominent max. which are given under conditions of imperfect polarization of the dropping-Hg cathode. Theoretical treatment of these anomalies is given in the present paper, and it is shown that the presence in soln. of a highly absorbable substance, *e. g.*, an org. dye, prevents this imperfect polarization and, therefore, the anomalous shape of the current-voltage curve. The max. occurring on current-voltage curves when solns. contg. electroreducible substances are electrolyzed with the dropping-Hg cathode are termed "positive" or "negative" according as they are given at potentials more pos. or more neg. than the abs. electrocapillary zero (*i. e.*, −0.56 v. from the *N* calomel zero). The shape of the electrocapillary curve, simultaneously derived from the polarized dropping Hg cathode, indicates the sign of the max. Just as the pos. branch of the electrocapillary curve is affected by the presence of adsorbable anions, and the neg. branch by adsorbable cations, the presence of such anions has been shown to affect the pos. max., while neg. max. have been shown to be sensitive to cations. The current-voltage

curves were obtained in the usual manner (*C. A.* **19**, 2905), and the electrocapillary curves by catching and weighing 50 drops of Hg (from the dropping cathode) at various applied e. m. fs. Adsorbable, or multivalent anions, such as CN^-, OH^- and SO_4^{--} and acidic dyes and neg. colloids, suppress pos. max., leaving the neg. ones unaffected, while multivalent cations, even in dil. soln., suppress neg. max. and are without effect on pos. ones. The degree of suppression of pos. max. given by the ion OH and that by the SO_4 ion are identical at equiv. concns., while that of the NO_3 ion is much less; this is exactly parallel to their respective effectiveness in the pptn. of $Fe(OH)_3$ sols.

EDWARD B. SANIGAR

The reduction potential of the ceric-cerous electrode. ADOLF H. KUNZ. *J. Am. Chem. Soc.* **53**, 98–102(1931).—Measurements at 25° of the e. m. f. of cells consisting of Pt + H_2, H_2SO_4 (0.5 or 1.0 *f*), H_2SO_4 (0.5 or 1.0 *f*) + $Ce_2(SO_4)_3$ + $Ce(SO_4)_2$, Pt. The e. m. f. was found to be 1.461 v. for 0.5 *f* H_2SO_4 and 1.443 v. for 1.0 *f* H_2SO_4. The activities of ceric and cerous ions are always proportional to the concn. of the respective salts.

E. G. VANDEN BOSCHE

A reënforced, colloidal, pseudo liquid diaphragm, designed for the electrolytic decomposition of water. GEO. F. JAUBERT. *Compt. rend.* **191**, 1447–9(1930).—If a KOH soln. (25 g. KOH in 100 g. H_2O) which contains in colloidal suspension a hydrogel such as $Fe(OH)_3$, $Ca(OH)_2$, colloidal asbestos, etc., is electrolyzed with a Ni anode and an Fe cathode, O_2 and H_2 are evolved, and the Ni anode gradually becomes covered with a uniform layer of the colloidal material several mm. thick. Similarly, if a screen of fine iron wire is interposed between the electrodes, it is covered by a uniform, pseudo-rigid layer of the colloid. This layer is of very low elec. resistance, but it is quite impermeable to the gases in their mol. form, it serves as a perfect diaphragm for the sepn. of the O_2 from the H_2. About 72 hrs. is required for its formation. Electrolytic cells provided with colloidal diaphragms of several sq. m. area, and operating with 5000 amp., produced H_2 100% pure, and O_2 99.5% pure. The 0.5% H_2 which occurs in the O_2 as an impurity will be the subject of a future note.

R. H. LOMBARD

The relation between the hydrogen overvoltage and composition of brass. M. DE KAY THOMPSON. *Trans. Electrochem. Soc.* **59** (preprint), 5 pp (1931).—The H overvoltages on brass are measured for compns. varying from pure Cu to pure Zn. The points on the overvoltage-compn. plot would lie nearly evenly distributed about a straight line drawn between the values for pure Cu and pure Zn, except for a decided min. in the brass. Max. have been found in other alloys, but this is the first sharp min. There is no close connection of the overvoltage with the equil. diagram.

C. G. F.

Hydrogen overvoltage. M. G. RAEDER. *Tids. Kemi Bergvesen* **10**, 37–40, 56–9 (1930); cf. *C. A.* **23**, 2091.—A theoretical discussion.

B. C. A.

Reduction of alkaline chlorites in electrolytic cells. G. R. LEVI AND D. GHIRON. *Atti accad. Lincei* **11**, 1104–7(1930).—The reduction of chlorites in neutral solns. has been studied by detg. the e. m. f. of a number of cells in which $KClO_2$ was one of the electrolytes. In all cases the positive side was Pt | $KClO_2$ (0.1 *M*). The cells studied and voltages at 20° were: KCl (0.1 *M*) + Hg_2Cl_2 | Hg, 0.363 v.; K_2S (0.2 *M*) | Pt, 1.19; KNO_2 (0.1 *M*) | Pt, 0.3905; $K_4Fe(CN)_6$ (0.025 *M*) | Pt; $Na_2S_2O_3$ (0.1 *M*) | Pt, 0.437; KI (0.1 *M*) | Pt, 0.285; $N_2H_4 \cdot H_2SO_4$ (0.1 *M*) | Pt, 0.370; $(NH_2OH)_2 \cdot H_2SO_4$ (0.1 *M*) | Pt, 0.350.

A. W. CONTIERI

Reactions occurring at the electrodes in electrolysis and some metallic compounds produced. A. P. ROLLET. *Ann. Chim.* [10], **13**, 137–252(1930).—Electrolysis with a c. of dil. aq. solns. of alkali or H_2SO_4 with Au or Pt electrodes, or of dil. alkali solns. with Ag electrodes, yields no evolution of gas until the c. d. exceeds a certain limiting value. The products of electrolysis appear to be fixed by the electrodes, with decompn. followed by recombination. This view is confirmed by the evidence of a Ag electrode being alternately coated with oxide and with powdery metal. Above a certain c. d. a point is reached at which the electrodes are unable to fix all the O_2 liberated during a half cycle, and the excess is given off, while the H_2 above the amt. equiv. to the Cr is similarly released. Au, Ni, Co, Fe, Cu and Pb behave like Ag, whereas Pt and Pd act in a reverse manner. Similar results are obtained when sol. electrodes are used. No decompn. of any kind occurs unless the max. c. m. f. in the cycle exceeds the decompn. tension for water with the particular electrodes used. The crit. c. d. in the electrolysis of KOH solns. to which CO_2 is added changes discontinuously when the amt. of CO_2 is just sufficient to convert the whole of the alkali into the normal salt, if the electrodes are of one of the metals which fix CO_2. From this it would appear that several degrees of oxidation are possible. It has been possible to study the oxidation by combining such an electrode, anodically polarized with a d. c., with a reference electrode and observing the c. m. f.-current strength relationship when the cell is allowed to dis-

charge. The formation of the oxide, Ag_4O_8, on a Ag electrode has thus demonstrated, and similar expts. with accumulator plates have yielded results supporting the theory that Pb subsulfate is formed on the neg. plate at discharge, but no definite evidence of the presence of Pb_2O_5 on the charged pos. plate could be obtained (cf. Féry, *C. A.* **13**, 1676; Féry and Chéneveau, *C. A.* **20**, 1181). In the Edison accumulator, the active material on the charged Ni plate is mainly NiO_2 if the alkali concn. exceeds about 6 *N*.

W. H. BOYNTON

The Volta effect in electrochemistry. OSCAR SCARPA. *Atti III congresso naz. chim. pura applicata* 1930, 83–94.—S. has devised an electrometer in which the displacement of a metallized quartz fiber suspended between two metal plates measures the p. d. between the plates. With this instrument he has measured the p. d. between a Zn and a Cu plate when they have been attached to the Zn and Cu electrodes, respectively, of a *Daniell cell*. He has also measured the p. d. between a Zn and a Cu plate connected by a Cu wire and between two Cu plates connected to the electrodes of a Daniell cell. In the first case the e. m. f. was 0.23 v., in the second 0.85 v., and in the third 1.08 v. The first case S. calls the true or surface Volta effect and ascribes it to the e. m. f. of contact between the electrodes and the solns. and between the two solns. The second or internal Volta effect is the contact potential of the two metals. J. B. AUSTIN

Formation of methane during the electrolysis of potassium acetate and the mechanism of Kolbe's electrosynthesis. S. N. SHUKLA AND O. J. WALKER. *Trans. Faraday Soc.* **27**, 35–40(1931).—Evidence has been obtained that CH_4 is formed at the anode during the electrolysis of aq. acetate solns. under certain conditions. It is suggested that the presence of CH_4 has been overlooked by previous investigators, because their analyses of the gaseous products of electrolysis have been confined almost entirely to the mixed anode and cathode gases (*i. e.*, to mixts. contg. a large proportion of H) resulting from electrolysis at high c. d. If it is assumed that only C_2H_6 and H are present in the combustible residue, after the removal of the other constituents, the presence of small amounts of CH_4 may remain undetected since $2CH_4 = C_2H_6 + H_2$, *i. e.*, the CH_4 simply acts as a mixt. of C_2H_6 and H. In the present work the anode gases were analyzed separately from the H given at the cathode. The combustible residue of the anode gas, after the removal of the O_2 and CO_2 in a Boue and Wheeler app. over Hg, was transferred to an evacuated tube and cooled in liquid air to remove the C_2H_6, the contraction after cooling being a measure of the C_2H_6 present. After some time the uncondensed gas was pumped off by a Topler pump and exploded. The ratio, contraction on explosion (*C*)/ amount of absorption by potash (*A*), was approx. 2, whereas the *C*/*A* ratio for the condensed gas was 1.25 (the theoretical ratio for C_2H_6), showing that CH_4 was present in the above anode gases. In the electrolysis a Pt wire anode (4.4 cm. long, 0.1 cm. diam.) was used, and the anode gases were collected separately. Solns. of K acetate (contg. an equiv. amount of acetic acid) of different concns. were electrolyzed at various c. ds. at ordinary temp. A table of exptl. results is given. The results show that under certain conditions CH_4 is present with C_2H_6 in the anode gases produced during the electrolysis of K acetate solns., the conditions favorable to the formation of CH_4 being low c. d. and high concn. of electrolyte. The quantity of CH_4 was appreciable only when the c. d. was less than about 10 ma./sq. dm. In the most favorable instance, with a 3.5 *N* K acetate soln. plus 3.5 *N* acetic acid, at a current of 1.5–2.0 ma., almost twice as much CH_4 as C_2H_6 was produced, the total exptl. results for this soln. being CO_2, 67.3, O_2 0.4, CH_4 19.8, C_2H_6 10.5 and residue 2.0%. The results also show that CH_4 is formed only along with C_2H_6; no CH_4 is evolved so long as O_2 is the main gaseous product. With ordinary c. ds. such as are used in the electrolytic prepn. of C_2H_6, no appreciable amt. of CH_4 is produced. The mechanism of Kolbe's electrosynthesis and the recent work of Fichter are discussed. The abnormally high value of 2.54 v. for the discharge potential of the acetate ion (as put forward by Preuner and Ludlam, *C. A.* **2**, 12) is not correct; C_2H_6 is evolved below this potential.

EDWARD B. SANIGAR

Self discharge of dry cells. SABURO MAKINO. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 521(1930).—To investigate the mechanism of self discharge a positive electrode only was immersed in an electrolyte, and the same electrode was immersed as an anode with the usual neg. electrode. Decrease of e. m. f. and capacity during open circuit occurs first at the anode, then gradually at the cathode, the degree depending upon the amt. of Fe contained as impurity in the MnO_2 used. E. M. S.

High-speed photographs of arcs in liquids. CHESTER LICHTENBERG. *Elec. World* **97**, 321, 323(1931).—Arcs sprung in insulating liquids ordinarily persist 0.01–0.1 sec. A high-speed, successive-image camera for studying these arcs is illustrated. It clearly records 24 individual successive images at a rate of 550 images per sec. The arcs were

started by opening a single-phase, 6000-v., 25-cycle a. c. carrying 50 amp. at 0.45 power factor. The same general phenomenon is observed in all the photographs. The arc starts at the contacts, and immediately oil or other liquids in the vicinity of the arc is gasified. A gas globule forms around the contacts. As the contacts continue to sep., the gas globule expands as a sphere till the sides of the containing vessel or a baffle plate alters its shape. Simultaneously the oil level is raised a distance proportionate to the size of the gas globule. Finally the arc punctures the globule, releasing the pressure within. Sometimes the release is violent. Then the oil level is distorted and broken, some oil being thrown upward. The remainder descends, cools the arc and extinguishes it. W. H. BOYNTON

A study of the physical processes in the so-called electrical purification of gases. II. The action of the electrical wind (Cottrell process). R. LADENBURG AND W. FIETZE. *Ann. Physik* [5], **6**, 581–621(1930); cf. *C. A.* **24**, 3447.—This is an investigation of the effect of the elec. wind (*EW*) on the velocity of dust particles being pptd. from a gas by elec. pptn. Using the corona discharge from a neg. charged wire to a grounded wall, the authors have found that for particles of diam. $\leqq 10^{-4}$ cm. the *EW* is the detg. factor on the velocity (v) which at 10^{-6} amps. and 5×10^{-6} amps./glow-discharge point is 0.56 and 1.23 m./sec., resp. v decreases with distance from glow-discharge point, being for 5×10^{-6} amps. at 3 mm. 1.20 m./sec. and at 60 mm. 0.80 m./sec. For particles of diam. $= 10^{-4} - 10^{-3}$ cm. the *EW* is still an important factor. The measurement of v made by comparing the effect of a current of air of known velocity with that of the *EW* on a stream of CO_2, tobacco smoke or CO_2 in a specially constructed cylindrical pptn. chamber was recorded photographically. Description and drawings of the app. and photographs of the effects are given. E. R. SCHIERZ

High-voltage surge testing—the cathode-ray oscillograph. F. D. FIELDER. *Elec.* [illegible] 28, 106–7, 119(1931).—The cathode-ray oscillograph accurately measures voltage and time relationships. It depends for its operation on the influence of elec. fields upon the electron beam. The Dufour and Norinder types are illustrated and their operations outlined. The deflection of the cathode ray by an elec. field is a pos. motion, and oscillograms indicate it with an accuracy of 2%. W. H. BOYNTON

1930 developments in electrical equipment for steel mills. H. A. WINNE. *Iron Trade Eng.* **8**, 21–5(1931).—The synchronous motor has very largely superseded the induction motor for const. speed mill drives, except where flywheels are necessary. The year's developments on d. c. main drives, switchgear, motor room ventilation, auxiliaries, *vacuum tubes* and *elec. furnaces* are noted. W. H. BOYNTON

Handbuch der technischen Elektrochemie. Band I, Hälfte 1. Die technische Elektrolyse wässeriger Lösungen. Edited by VICTOR ENGELHARDT. Leipzig: Akad. Verlag. 613 pp. M. 56; bound, M. 58. By subscription, M. 50.40; bound, M. 52.20.

Dry cell electric battery assembly. SIEMENS & HALSKE A.-G. Brit. 335,758, Oct. 19, 1928. Structural features.

Electric dry cell battery assembly. JOHN S. ZOOK (to Burgess Battery Co.). U. S. 1,790,784, Feb. 3. Structural features.

Storage battery. SOLOMON L. VAN MEYER, JR. U. S. 1,791,152, Feb. 3. Structural features.

Alkaline storage battery. J. J. DRUMM and CELIA, LTD. Brit. 335,587, March 27, 1929. Ag or Ag oxide mixed with Ce oxide is employed as active material for the pos. electrode. Various details of prepn. are given.

Storage-battery plate. ALBERT S. HUBBARD (to Gould Storage Battery Corp.). U. S. 1,791,208, Feb. 3. In making a tubular container to form a part of a storage-battery plate and to contain a core surrounded by active material, a sheet of non-porous insulating material such as hard rubber stock is rolled out, laminae of porous material such as cloth, wood or felt are embedded in the sheet, and the latter is cut into a plurality of washer-like sections which are then stacked and vulcanized.

Selenium cell. HANS THIRRING (to "Selenophon" Licht- und Tonbildges. m. b. H.). U. S. 1,790,850, Feb. 3. Various details of manuf. are described.

Accumulators. MAURICE MATROT. Fr. 692,917, June 27, 1929. The electrolyte of an accumulator having a Zn neg. electrode is composed, *e. g.*, of H_2SO_4 (45°Bé.) 500 cc., $ZnSO_4$ 350, dimethylglyoxime 4, Na_2SO_4 50 and $MgSO_4$ 20 g.

Tin plating. SIEMENS & HALSKE A.-G. Fr. 692,813, Mar. 27, 1930. In the electrolytic formation of coatings of Sn of any thickness, alk. electrolytes and sol. or insol. anodes being used, the content of free alkali is kept between the limits of 1.5 and 8%, so that no spongy formation is produced during the time necessary to obtain the desired thickness of Sn.

Electrolytic production of chemical compounds. ANTONIO L. CLARIANA. Fr. 693,150, April 2, 1930. In electrolytic processes for the production of chem. compds. the cathode is made of or coated with a metallic sponge of finely divided metallic particles which are easily oxidized in contact with the air. The operation is intermittent, the cathode, when reduced by the H produced, being brought into the air until again oxidized.

Electrolytic apparatus for cleaning the surface of metals. THE BULLARD CO. Fr. 693,199, April 2, 1930.

Electrolytic gas generator. PAUL HAUSMEISTER. Ger. 514,391, April 20, 1924.

Electrolytic refining of copper. UNITED STATES METALS REFINING CO. Fr. 693,678, April 10, 1930. The cathode used in the refining of Cu have parallel corrugations extending in 2 different directions.

Electrolyte for the production of iron or iron alloys. ORLANDO ORLANDI. Fr. 693,812, April 12, 1930. See Belg. 360,116 (*C. A.* **24**, 793).

Electrolytic manufacture of tungsten, etc. HELLMUTH HARTMANN. Ger. 514,365, Sept. 11, 1928. W is manufd by electrolyzing a soln of WO_3 in fused alkali phosphate, with or without H_3PO_4 or other phosphates. An example is given. Other heavy metals, *e. g.*, Mo, Ta, V and Nb, may be extd. similarly.

Electrolytic zinc bath. GIUSEPPE BIANCO. U. S. 1,791,082, Feb. 3. A bath suitable for use in coating iron or steel with Zn is formed from a Zn amalgam, alkali metal phosphate, H_2SO_4, $Al(OH)_3$ and water.

Light metals. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 692,491, Mar. 21, 1930. In electrolyzers for the prepn. of light metals by electrolysis of their molten halogen salts, a cathodic arrangement for gathering the light metal formed is used. It is composed of an exteriorly insulated metal piece in the form of a longitudinal channel, or provided on its lower face with longitudinal channels, in elec. connection with the cathode which is placed below the said piece parallel to the direction of the channels and descends relatively low into the electrolyte.

Magnesium. THE MAGNESIUM PRODUCTION CO., LTD. (Pierre Cames-Casse, inventor). Fr. 693,387, Apr. 4, 1930. In the manuf. of Mg by the electrolysis of a soln. of $MgCl_2$ and KCl, a part of the electrolyte is removed from the vat, and $MgCl_2$ is added so that the compn. of the electrolyte is maintained practically constant and the KCl follows a closed cycle.

Purifying liquids. JEAN BILLITER. Fr. 693,799, April 12, 1930. Liquids are purified electrolytically, while suppressing electroosmosis as much as possible, by using mean differences of tension of less than 20 v. (preferably 8–16).

Hydrogen from water. ALBIN WERLEN THIÉBAUT KUENEMANN, ÉDOUARD SILBERMANN and CHARLES GOETSCH. Fr. 693,637, Jan. 21, 1930. In the production of H from water an anode composed of a Hg-Cu-Zn catalyst, a depolarizer composed of an alkali phosphate and an Al cathode are used.

Butyl alcohol. R. RILEY, S. W. ROWELL and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 335,683, Aug. 13, 1929. BuOH obtained by the catalytic hydrogenation of aldol, crotonaldehyde or butylaldehyde is purified by electrolytic reduction in aq. electrolyte, either acid or alk., such as H_2SO_4 or $NaHSO_3$ soln. The product may sep. into 2 layers, the upper of which when neutralized and distd. forms a distillate also sepg. into 2 layers, the upper of which contains the purified BuOH substantially free from aldehyde.

Electric furnace for aluminum manufacture. PEDER ELIASEN FRÖLAND. Ger. 515,229, Mar. 6, 1928.

Induction furnace. EMIL F. RUSS. Ger. 514,357, Dec. 12, 1929.

Electric induction crucible furnace. C. LORENZ A.-G. Brit. 335,766, Oct. 25, 1928. Structural and elec. features.

Electric-arc furnace suitable for making tungsten carbides. OSCAR L. MILLS (to Mills Alloys, Inc.). U. S. reissue 17,954, Feb. 3. Reissue of original pat. No. 1,719,558 (*C. A.* **23**, 3863).

Heating elements for electric furnaces. EMIL F. RUSS. Fr. 693,413, April 5, 1930.

Apparatus for electrical precipitation of suspended particles from gases. HARRY WINTERMUTE (to Research Corp.). U. S. 1,791,338, Feb. 3. Structural features.

Apparatus for electrical precipitation of suspended particles from gases. HARRY V. WELCH (to International Precipitation Co.). U. S. 1,790,961, Feb. 3. Structural features.

Armoured electric deep-sea cables. FELTEN & GUILLEAUME CARLSWERK A.-G. Brit. 335,804, Jan. 23, 1929. Various structural details are described of cables with a pressure-protecting covering formed of profile wires and covered by a water-tight sheathing of gutta percha, "gutter-gentzch" or washed rubber.

Electric incandescent lamps. N.-V. PHILIPS' GLOEILAMPENFABRIEKEN. Brit. 335,617, June 29, 1929. Various structural details are described of a lamp which is adapted to be mounted within a parabolic reflector and the bulb of which is preferably colored by surrounding it by a template or stencil and spraying with a "Bakelite" lacquer. A yellow layer may be obtained by burning in Ag oxide.

Metal filament for incandescent electric lamps. C. SENEN. Belg. 370,823, July 31, 1930. The filament is formed of an alloy of W, Th, Ir, Ni and Cr, or of an alloy of W, Th and Zr. It has an elongated cross-section, either an ellipse or a double parabola.

Lamp filaments. SOC. D'ÉTUDES SCIENTIFIQUES ET INDUSTRIELLES. Fr. 693,275 June 1, 1929. Filaments for wireless lamps are made of Ba_3N_2 or Ba alloys such as Na-Ba, Bi-Ba or Sn-Ba. Cf. *C. A.* **25**, 1170.

5—PHOTOGRAPHY

E. P. WIGHTMAN

Preparation of fine grain emulsions. E. FUCHS. *Phot. Ind.* **28**, 1172–4(1930).—The graininess observed in photographic materials is due to the clumping or aggregation of grains rather than to the individual grains themselves. Other things being equal, graininess is proportional to the size of the individual grains, but the prepn. of fine grain emulsions is largely a matter of colloidal principles aimed at preventing formation of aggregates of grains. In the ammonia process, substitution in part by Na_2CO_3 is recommended for the first ripening, followed by a quick second ripening of the well-washed material. C. E. MEULENDYKE

Preparation of silver bromide emulsion. MARX REO, T. NISHIMURA, H. HAYASHIHARA, T. ASAI AND S. MURATA *Repts. Imp. Ind. Research Inst. Osaka, Japan* **11**, No. 13(1930).—The methods of prepn. of AgBr emulsion together with its properties are given. F. I. NAKAMURA

Solubility of silver bromide in photographic emulsion. MICHIO MIYATA. *Repts. Imp. Ind. Research Inst. Osaka, Japan* **11**, No. 12 (1930). —The use of the pptn. method in detg. the solv. of AgBr in photographic emulsions is given. F. I. NAKAMURA

Toning by addition. S. JASIENSKI. *Atelier Phot.* **37**, 113–5(1930).—Processes for toning Ag images fall into two groups: the substitution methods, in which the Ag of the image is changed to another form, as Ag_2S, and the addn. methods, in which some substance is added to the Ag, as the U toning process. The final deposit obtained when a $HgCl_2$ bleach is used for sulfide toning is partly sol. in Farmer's reducer. It cannot, therefore, be Ag_2S but is probably a complex Hg-S compd. H. PARKER

Alkaline selenosulfates and their use for the toning of silver images. A. SEYEWETZ. *Sci. ind. phot.* [2], **1**, 436; *Rev. franç. phot.* **11**, 332; *Photographe* **17**, 475–6(1930).—Seleno-sulfates can be obtained from NH_4, Li, Na and K sulfites. Because of its great soly. the last is the most interesting. On dilg. a concd. soln. of K selenosulfate with water, Se is pptd., but on dilg. with a K_2SO_3 soln., the soln. remains colorless. Silver selenosulfate decomposes, readily pptg. Ag_2Se; hence, the soln cannot be used to tone prints. Several prints may be fixed and toned simultaneously with a fresh soln. of hypo contg. in addn. K selenosulfate. After fixing 2 or 3 prints, however, clear whites are no longer obtained because of the decompn. of the Ag selenosulfate. L. A. STAIB, JR.

History of the invention of silver chloride developing-out paper of the Velox type. R. NAMIAS. *Il prog. fot.* **37**, 397(1930).—In a discussion of this subject, Eder claimed that AgCl papers were originated by himself and Pizzighelli. Baekeland replied that in his papers the emulsion was not washed, and that the present type of developing-out paper therefore originated with the introduction of Velox. Baekeland's claims are supported by N. C. E. K. MEES

Determination of so-called Ur-silver in photographic gelatin. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **28**, 293–7(1930); cf. *C. A.* **25**, 42.—The previous

differentiation of the Ag content between atomic Ag and an organic Ag compd. does not hold. The Ag is not the result of the action of $AgNO_3$ on gelatin, but is due to differences in the diffusion velocities of Ag and halogen ions within the gelatin during washing. Ag halide and Ag formed by exposure cannot be sepd. with neutral $Na_2S_2O_3$. The best available substance is Na_2SO_3. Its use, however, is limited to the investigation of AgCl and AgBr. A. P. H. TRIVELLI

Origin and the chemical nature of the silver content. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **28**, 302-11(1930).—The Ag content arises by hydrolysis through differences in the diffusion velocities of halogen and Ag ions and consists of Ag_2O. This Ag_2O has a tanning action on gelatin, forming a difficultly sol. complex. The total amt. of detectable Ag_2O in the gelatin after washing depends upon the relations between the soly. of Ag halide and the Ag_2O gelatin complex. With the same soly. of the Ag complex, the Ag content increases with increasing soly. of the Ag halide. The total amt. of Ag_2O formed very quickly approaches a limit when as much Ag_2O dissolves as is formed by hydrolysis of Ag halide. The Ag content resulting from AgCl is perfectly sol. AgBr and AgI were also studied. It is possible that the Ag_2O formed by hydrolysis influences ripening. In any case, Ag_2O is more easily reducible than Ag halide. A. P. H. TRIVELLI

Silver content and the fixing process. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **28**, 297-302(1930); cf. *C. A.* **24**, 2069.—The soly. of Ag is less in Na_2SO_3 than in $Na_2S_2O_3$ soln. Therefore, the total removal of Ag from a washed emulsion by Na_2SO_3 soln. is due to a sol. Ag compd. which has been shown to give Ag ions. The very small amts. of Ag left in the emulsion are of the same order as those obtained if pure gelatin is treated with thiosulfate and the sulfite complex compd. solns. Very probably this Ag is Ag_2S. The soly. of Ag in thiosulfate solns. is too great for the use of the latter in accurate analytical investigation. A. P. H. TRIVELLI

Mechanism of the color change of silver images due to selenium. A. SEYEWETZ. *Sci. ind. phot.* [2], **1**, 435(1930).—Se dissolved in alkaline sulfites or sulfides can be used to tone Ag images. Sodium selenosulfate and sodium selenosulfide react with Ag to give Ag_2Se. This reaction has been verified by removing the image from plates and paper and detg. analytically the ratio of Ag to Se. A slightly larger percentage of Se was found in the selenosulfate toned image. Satisfactory agreement with the theoretical ratio was obtained for the selenosulfide image. L. A. STAIB, JR

Orthochromatism, panchromatism and dye filters. GUILLIMINOT AND BOESPFLUG. *Photo-Revue* **42**, 309-11, 325-6(1930).—An estn. of the chromatic sensitivity of negative materials may be obtained: (1) by photographing a color chart with and without filters, (2) by means of the Eder-Hecht sensitometer wedge; (3) by means of spectrographic curves. Examples of each method are shown. H. D. RUSSELL

Glycocoll-copper for daylight filter. R. LUTHER. *Kinotechnik* **12**, 453(1930).—The advantages are: (1) it is easy to prepare in C. P. form and easy to compound; (2) it contains no volatile and easily oxidized material; (3) it is neutral and does not attack the glass walls of the cell; (4) it is practically stable with time; (5) the absorption is more independent of temp. The disadvantages are: (1) the soln. can develop mold, (2) it is sensitive to alkali and acid, its prepn. being thus made more troublesome; (3) its soly. is low at room temp. If necessary, a greater thickness of cell may be chosen. The extinction curve is shifted 8 or 10 mμ farther toward the red, and the density is less in the ultra-violet than is that of the Davis-Gibson filter. It appears to give a closer match to the curve of the ideal filter than does a $CuSO_4$-pyridine-mannitol cell. O. E. M.

Raising the sensitivity of bichromated colloid films. K. JACOBSOHN AND E. WAGNER. *Atelier Phot.* **37**, 98-100(1930).—The addn. of $CeCl_3$ to the sensitizing bath as advised by F. J. Tritton, was not found to increase the sensitivity of bichromated gelatin. Bathing in a soln. of methylene blue after the usual sensitizing with $K_2Cr_2O_7$ gave increased red sensitivity. The loss in the green and yellow balances the gain in the red, so there is no gain in the total sensitivity. H. PARKER

Oleobrom. J. D. JOHNSTON. *Camera* (Dublin) **10**, 235-6(1930).—Technic of bromoil making is simplified by the introduction of a new bromide paper. The developed print is bleached and dried in the usual way. The dry print is charged with ink from a special roller. The print is then placed in water and a clean roller run over the print. This rolling removes the ink from the highlights and deposits it on the shadows. After the proper contrast has been obtained, the print is removed from the water and is either dried or the tones altered by hand manipulation. R. A. PURDY

New photochemical effect on celloidin paper as a radiation problem. H. MEWES. *Z. wiss. Phot.* **28**, 311-24(1930).—AgCl papers exposed to different substances (ele-

ments of the periodic system) in a nonconducting box of ebony, or metal-free, colorless paper maché, and developed in dild. rodinal developer (1:825) at 18° for 15 min., give pictures which show the effect of radiation and not the effect of emanation of H_2O_2. This radiation M. calls *L-rays*. Different properties of these L-rays are discussed.
A. P. H. TRIVELLI

Testing wash water for hypo. *Atelier Phot.* **37**, 117-8(1930).—Several methods are described for testing for the presence of $Na_2S_2O_3$: (1) A dil. (light red) soln. of $KMnO_4$ is decolorized in less than a min. after the addn. of water contg. $Na_2S_2O_3$. (2) Two cc. of a 1% soln. of $AgNO_3$ acidified with HAc, mixed with a glass full of the wash water, give a brown color if $Na_2S_2O_3$ is present. (3) A drop of satd. $HgCl_2$ soln. added to a small amt. of the wash water gives a brown color with $Na_2S_2O_3$ present. The method of Crabtree and Ross using a soln of $HgCl_2$ and KBr is also described. H. PARKER

Ferrous oxalate developer. SPÖRL. *Atelier Phot.* **37**, 100 2(1930).—For over-exposures, the FeC_2O_4 developer gives better results than dild. or restrained org. developers, and the time of development is normal. Two stock solns. are used: (*A*) 1:3 (33%) $K_2C_2O_4$ and (*B*) 1:3 (33%) $FeSO_4$, with a drop of H_2SO_4. Three parts of *A* to one part of *B* gives the strongest developer, increasing the proportion of *A* weakens it, or KBr may be added to correct overexposures still further. One or 2 drops of hypo increases the energy, but an excess causes fog. A good reducer may be made from the used developer. Fifteen g. of oxalic acid is dissolved in a liter of the heated developer. The green crystals of ferric potassium oxalate formed when the developer cools are made up as a 1:20 soln., and hypo is added equal to 5 times the wt. of the green crystals whose action is between that of $K_3Fe(CN)_6$ and persulfate.
H. PARKER

Is the blackening and blanching of exposed lithopone a photographic phenomenon? (STOBBE) **3.** The Spierer lens and what it reveals in cellulose and protoplasm (SEIFRIZ) **11A.**

Photographic coating sensitive to electronic discharge. AUSTIN G COOLEY. U. S. 1,791,053, Feb. 3 Finely divided conducting particles such as metal are distributed through a sensitive coating to render it suitable for use in recording app.

Three-color cinematograph film. LEON J. B. DIDIER. U. S. 1,790,978, Feb. 3. A blue image is printed on one face of a film coated on one side with a gelatin bromide layer and on the other with a neutral gelatin layer; the film is coated with a soln. of a dichromate, and there are printed simultaneously on the sides of the film a yellow and a red image, resp., the film being then dried and provided with a colored gelatin strip on each side.

Production of colored photographic and cinematographic positives. L. J. DASSONVILLE. Belg. 372,003, Aug. 31, 1930. A Ag salt image is first produced in the sensitized emulsion. After resensitization by means of a salt of another metal, a 2nd image is produced It is obtained colored by pptn. of a colored salt.

Photographic plates and films. I. G. FARBENIND. A.-G. Fr. 693,659, April 10, 1930. Anti-halo layers for photographic plates and films contain fuchsone dyes with one or more COOH groups in the mol. Examples are given of the use of aurindicarboxylic acid, aurinmonocarboxylic acid and hydroxycarboxyfuchsone.

Light-sensitive layers. KALLE & CO. A.-G. Fr. 693,032, Mar. 29, 1930. Light-sensitive layers are prepd. on appropriate supports using diazo compds. of aromatic amino-acylamines of the general formula NH_2 R NH CO X and NH_2 R NH.CO.NH R' NH_2 in which R and R' are substituted or unsubstituted groups and X is an aliphatic, aromatic or aliphatic-aromatic group and the CO may be replaced by CS. Examples are given.

Protecting surfaces. VLADIMIR REVOS. Fr. 692,800, Mar. 26, 1930. Fragile surfaces such as photographic negatives or papers, films, pictures, etc., are protected by a thin layer of a transparent soln. of celluloid, etc., in an appropriate solvent such as AcOAm.

Printing molds. ERNST BECHERT. Fr. 692,794, Mar. 26, 1930. In the production of printing molds, safranine or like substance is added to the light-sensitive layer to neutralize the latteral or undesired illumination.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Researches on the role of water in the salts: aquo combinations of ruthenium-IV-ammines. R. CHARONNAT. *Compt. rend.* **191**, 1453-5(1931).—In partial support of his theory of hydrolysis Werner made use of certain transformations of salts of Ru-IV-nitrosohydroxotetrammine which are caused by suitably heating the salts with acid, namely: $X_2[Ru(NO)(OH)(NH_3)_4]$ (I) $\longrightarrow$ $X_3[Ru(NO)(H_2O)(NH_3)_4]$ (II) $\longrightarrow$ $X_2[Ru(NO)(NH_3)_4]$ (III). In his investigation of the role of water in salts of type II, C. prepd. 2 new salts having the compns. $Ru(NO)en_2Cl_2.H_2O$ and $Ru(NO)py_2Cl_3.H_2O$ (en = ethylenediamine and py = pyridine). The properties of these complex aquo salts indicate that they are really hydrochlorides of hydroxides having the following structures: $Cl_2[Ru(NO)(NH_3)_4(ClHOH)]$, $I_2[Ru(NO)en_2(ClHOH)]$, and $[Ru(NO)py_2(ClHOH)Cl_2]$. The mol. of HCl is joined to the O of the group (HCl . . . O A) by a secondary valence, the O possessing tri-coordinance. R. H. LOMBARD

A new method for the conversion of alkali sulfate to alkali chloride for use in silicate analysis. WERNER MYLIUS. *Sprechsaal* **63**, 972-5(1930).—A new method for converting the alkali sulfate to the chloride in the quant. detn. of K and Na in silicates to replace the more bothersome $BaCl_2$ method consists in a double evapn. of the finely pulverized neutral sulfate with $N_2H_4.2HCl$. C. H. LORIG

The reaction between iodic acid (alkali iodates) and hypophosphorous acid, phosphorous acid or their salts. (II). V. HOVORKA. *Collection Czechoslov. Chem Comm* **2**, 609-25(1930)(in French); cf. C. A. **25**, 468. This part deals with the oxidation of the lower acids of P by HIO_3 in the presence of substances capable of removing, by the formation of insol. iodides, the I produced by the reaction between the HIO_3 and the HI formed during the oxidation of the phosphorous acids. Salts of Pb, Ag, Hg^{++} and Cd were used, but with Pb and Cd salts free I was always formed. Excess of the perchlorates of Ag and Hg^{++} was finally used. The work was carried out with acidified (H_2SO_4) alkali phosphite or hypophosphite solns. to which KI and excess metallic perchlorate were added. With Ag and Hg^{++} perchlorates the corresponding iodides were formed, so that very little direct oxidation of the acids by the HIO_3 occurred. The oxidation in the presence of $AgClO_4$ was complicated by the pptn. of almost all the I present as $AgIO_3$ when the $AgClO_4$ was added, and also by the reduction of the $AgClO_4$ to finely divided Ag. The results show that only half the H_3PO_2 was oxidized. After the oxidation the soln. contained principally H_3PO_3 and very little H_3PO_4. H_3PO_4 only began to be formed after about 50% of the H_3PO_2 had been oxidized. At ordinary temp. the oxidation of H_3PO_2 to H_3PO_3 was the main reaction, the oxidation of H_3PO_3 alone was always slow. With $Hg(ClO_4)_2$ no HgI was pptd. since it dissolved in the perchlorate immediately on formation. As with the Ag salts, the Hg^{++} salts were the real oxidizing agents of the phosphorous acids. The Hg^{++} salts oxidized both H_3PO_2 and H_3PO_3 to H_3PO_4, while $AgClO_4$ only oxidized the H_3PO_2 to H_3PO_3. The oxidation by the Hg^{++} salt occurred at ordinary temp., the rate depending on the quantity of $Hg(ClO_4)_2$ present. According to the quantity of Hg^{++} salt added, either the Hg^{+} salt alone, or the Hg^{+} salt and metallic Hg, were formed. Detailed descriptions of the courses of the reactions, of solns. obtained and of ppts. formed are given, together with detailed equations representing the various oxidations. EDWARD B. SANIGAR

The reduction of soda by hydrogen. P. VILLARD. *Compt. rend.* **190**, 1329-31 (1930).—A study was made of the action of H at high temp. upon free alkali, soda by preference because of the ease with which one can detect Na vapor. A current of H was passed over fused soda spread on the internal wall of a tube of extremely refractory glass or contained in a tube of Ag lightly closed at both ends to retain the soda and placed in the glass tube. The results were as follows: At 800° in the heated part of the tube contg. the soda the current of H was charged with vapors absorbing Na light very strongly. With a spectroscope and white light the absorbing vapor gave the characteristic spectrum of Na. It did not seem to be a question of dissocn., even at the higher temps. utilized (in the neighborhood of 900°) since the phenomena of the absorbing vapor disappeared entirely when H was replaced by N. R. H. CARTER

The system: thorium nitrate-ether-water between 0° and 20°. P. MISCIATELLI. *Gazz. chim. ital.* **60**, 833-8(1930).—It is necessary to have data on the quaternary system: $UO_2(NO_3)_2$-$Th(NO_3)_4$-H_2O-Et_2O, and therefore in turn of the ternary systems: $UO_2(NO_3)_2$-Et_2O-H_2O and $Th(NO_3)_4$-Et_2O-H_2O, to establish the conditions for the sepn.

of Th from U in the presence of water by the aid of Et_2O (cf. M., *C. A.* **23**, 1554). Of the systems: Et_2O–H_2O, $Th(NO_3)_4$–Et_2O and $Th(NO_3)_4$–H_2O, only the latter is unknown, so this was first studied. The following data give the temp. and the no. of g. of $Th(NO_3)_4$ in 100 cc. of satd. soln.: cryoscopic method: —0.2, 1; —0.5, 2; —1, 5.2; —1.5, 9; —2.1, 13; —2.9, 16; —4, 20; —4.6, 23.5. —5.4, 26.4; —5.6, 27.3; —6, 33; —6.6, 37; —9, 41; —11.2, 43; —12.2, 44.5; —13.5, 46.2; —15, 47.7; —16.6, 49.8; —19.1, 51; —23.3, 53.1; —25, 55.7; —28.6, 58; —31.3, 59.2; —35, 60.6; —40.6, 62; —43.5, 64; synthetic method: —43.5, 64 ($Th(NO_3)_4.6H_2O$); analytic method: —22, 64.2; 0, 65; 10, 65.2, 20, 65.6. Equil. in mixts. of $Th(NO_3)_4$, Et_2O and water was very slow, in some cases 20 days being required. The results of the measurements at 0° and 20° are given in tables and triangular diagrams, which must be consulted for the quant. data. The method used for obtaining these data is described in detail. In the *prepn. of anhyd.* $Th(NO_3)_4$, the ordinary nitrate was freed of traces of Ce by pptn. with $Na_2S_2O_3$ and H_2O_2, crystn. as $Th(NO_3)_4$, distn. of N_2O_5 over this to remove $4H_2O$, and treatment of the residue with a current of dry air for several days. C. C. Davis

The system: uranyl nitrate–ether–water between 0° and 20°. P. Misciatelli. *Gazz. chim. ital.* **60**, 839–42(1930). The binary systems: Et_2O–H_2O, $UO_2(NO_3)_2$–Et_2O and $UO_2(NO_3)_2$–H_2O are already known. Equil. in the ternary system was much more rapid than with $Th(NO_3)_4$–Et_2O–H_2O. A method of *prepn. of anhyd.* $UO_2(NO_3)_2$ was developed, viz., by distg. its mixt. with N_2O_5 and drying the residue in a current of dry air at 110°. Incipient decompn. of the anhyd. salt is obvious from a change in color to orange-yellow. No basic salts are formed in this thermal decompn. (cf. Guempel, *C. A.* **24**, 2367). The data for the isotherms at 0° and at 20° are given in tables and triangular diagrams, which must be consulted for the quant. values. Cf. preceding abstr. C. C. Davis

The structure of hydrogen phosphide and of hydrogen arsenide. G. Natta and E. Casazza. *Gazz. chim. ital.* **60**, 851–9(1930). In previous expts. on the structure of hydrides of elements of the 5th and 6th groups (cf. N., *Giorn. chim. ind. applicata* **12**, 37(1930)), analogies were found in the form and dimensions of the elementary cells of NH_3, PH_3 and AsH_3, but this was limited to a comparison of the lattice consts., and it was not proved whether a perfect isomorphism exists. In the present paper, more refined methods have made it possible to settle this problem. Of the binary compds. of H with elements of the 5th group, only NH_3 has been studied by the x-ray powder method (cf. Mark and Pohland, *C. A.* **20**, 130; de Smedt, *C. A.* **20**, 1735), but the arrangement of the atoms in the mol. was not established. A new examn. of NH_3 gave x-ray photographs of extraordinary clearness, and these will be described in a later paper, with the data of the structure. The lattice const. at —170° was 5.08 A. U., a value lower than that of the other experimenters, probably because of the thermal contraction at the lower temp. SbH_3 and BiH_3 appeared to be isomorphous but of a different structure from NH_3, PH_3 and AsH_3. However, the weakness and lack of clarity of the lines leave this problem unsettled. Good results were obtained with PH_3 and AsH_3. PH_3 was prepd. from Ca phosphide and water and purified by drying with $CaCl_2$, freezing out of heavier hydrides and sepn. from H by solidification with liquid air. It b. —87.4° and m. —132.5°. AsH_3 was prepd. from pure Zn and As_2O_3 in aq. HCl, drying with $CaCl_2$ and freezing of the AsH_3 with liquid air. Examn. of both PH_3 and AsH_3 was carried out with an app. already used (cf. N., *C. A.* **24**, 4973). At approx. 100° (abs.) PH_3 and AsH_3 are quite stable and do not oxidize in air, even when traces of other H phosphides or arsenides are present. PH_3 crystallizes in the cubic system. Its elementary cell contains 4 mols., has a dimension of 6.31 ± 0.01 A. U. at —170° and a vol. of 251×10^{-24} cc. Its d. is 0.896. AsH_3 is isomorphous with PH_3. Its elementary cell contains 4 mols., with a dimension of 6.40 ± 0.02 A. U. at —170° and a vol. of 262×10^{-24} cc. Its d. is 1.96. The position of the P and As atoms corresponds to a face-centered structure. The x-ray data did not permit the establishment of the position of the H atoms in the lattice. From considerations based on the size of the constituent atoms, it is probable that both PH_3 and AsH_3 belong to 1 of the 2 spatial groups Th^2 and Oh^4. The relations between these and the structure of NH_3 will be the subject of a later paper. C. C. Davis

Salts of bivalent vanadium. Julius Meyer and Margot Aulich. *Z. anorg. allgem. Chem.* **194**, 278–92(1930). The soly. of specially purified V_2O_5 in various concns. of H_2SO_4 is tabulated. If 3 g. of V_2O_5 is dissolved in 30 g. of 10% H_2SO_4, the soln. diluted and reduced with SO_2, blue vanadyl sulfate is produced. Electrolysis of the SO_2-free soln. in an inert atm. with a Pt, Pb or Hg cathode, 8–10 v. and 2–3 amp. causes further reduction. Purple crystals of $VSO_4.7H_2O$ (I) sep. upon evapn. This product

is very unstable. The NH_4, K and Pb complexes, *e. g.*, $(NH_4)_2V(SO_4)_2.6H_2O$, are more stable. Treatment of I with alkali salts of other acids gives only solns. Salts of org. acids decompose readily. Soln. of metallic V in mineral acids yields green vanadic solns. The metal as cathode or anode does not form V^{++}. B. A. SOULE

Germanium. XXXVI. Extraction of germanium and gallium from germanite. I. W. I. PATNODE AND R. W. WORK. *Ind. Eng. Chem.* **23**, 204–7(1931).—About 1200 g. of germanite is chlorinated and the volatile chlorides are distd. The distillate includes the anhyd. chlorides of Ge, As, Si, S and Ga. These are subjected to fractional distn. This distillate contains HCl and $GeCl_4$, which are sepd. by gravity. The $GeCl_4$ may then be hydrolyzed again to the dioxide. The yield is 85–90% of the Ge content of the ore. AMY LE VESCONTE

The halides of the rare earths. IV. Samarium diiodide and the thermal decomposition of samarium triiodide. G. JANTSCH AND N. SKALLA. *Z. anorg. allgem. Chem.* **193**, 391–405(1930).—Pure anhydrous SmI_3 is prepd. by treating a mixt. of 1 mol. of ordinary H_2O-contg. SmI_3 and 6 mols. of NH_4I with a current of HI, the temp. being gradually raised to 350° and finally to 600–650° to remove NH_4I. After cooling the HI is replaced with N. To avoid the formation of basic salts the gases must be quite dry and free from O. SmI_3 so obtained can be reduced to SmI_2 by heating in a Au boat in a current of dry H, the temp. being raised slowly in the course of 11 hrs. to 750–760° and held at this temp. for 1.5 hrs. After cooling the tube is filled with pure N. SmI_2 is a deep green, almost black in color, and dissolves in H_2O to give a deep red color. The soln. evolves H_2 and is gradually decolorized with sepn. of a basic Sm^{III} salt. SmI_2 is more stable than the chloride but is vigorously decomposed by acids, even AcOH, with evolution of H_2. The thermal decompn. of SmI_3 was carefully studied in a quartz tube under a pressure of 0.01 mm. of Hg. The temp. rose to 800° in 4 to 5 min. At 550–570°, I began to come off, the reaction being very vigorous at 680–720°. Above 750° evolution of I was very slight. The material was heated at 800° for 45 min., then at 900° for 15 min., and then allowed to cool, an atm. of pure dry N being finally admitted. The product of this decompn. is SmI_2. SmI_2 at 680° reacts as follows: $3SmI_2 \longrightarrow Sm + 2SmI_3$. SmI_3 melts with decompn at 840° and is extremely sensitive to H_2O, forming a red basic iodide in a few mins. in air. Cond. measurements verify the rapid decompn. of SmI_2 in H_2O solns. as follows: $2SmI_2 + 2H_2O \longrightarrow 2Sm(OH)I_2 + H_2$. If SmI_2 is dissolved in air-free H_2O at 0° and treated with a cold satd. soln. of Na_2SO_4, $SmSO_4$ is pptd. It is a bright, orange-red cryst. powder, slowly decomposed by H_2O and sol. in acids with decompn. H. STOERTZ

Trichloromethyl perchlorate. L. BIRCKENBACH AND J. GOUBEAU. *Naturwissenschaften* **18**, 530(1930).—In presence of a little HCl, CCl_4 reacts with $AgClO_4$ at the ordinary temp., yielding trichloromethyl perchlorate, CCl_3ClO_4, in 60–70% yield. By repeated fractionation in a vacuum in absence of moisture this can be obtained as a colorless liquid which solidifies at about −55° to colorless crystals. With water it yields $HClO_4$ and liberates I with iodides. With ale. and other org. substances, *e. g.* tap grease, it reacts at the ordinary temp. with detonation. When heated it explodes, liberating Cl. B. C. A.

The action of bivalent metals on persulfates of the alkali group. Synthesis of double salts of the type $M_2^+M^{++}(SO_4^{--})_2$. OSSIAN ASCHAN. *Z. anorg. allgem. Chem.* **194**, 139–46(1930).—Reduction of K, Na or NH_4 persulfates with metallic Cu, Mg, Zn, Cd, Mn, Fe, Ni or Co gives a double salt, *e. g.*, $K_2Zn(SO_4)_2.6H_2O$. The reaction is practically quant. B. A. SOULE

Alkyloxyvanadylsalicylates. P. BRAUMAN. *Compt. rend.* **192**, 166–7(1931).—MeOH (or EtOH(+$VOCl_3$ + $LiOC_6H_4CO_2Me$ gives $MeO(VO)OC_6H_4CO_2Me$ (or the EtO compd.) These are analogous to the Mo (Rosenheim et Bertheim, *Z. anorg. Chem.* **34**, 440(1903)) and the Cu and Ni compds. (Doak and Packer, *C. A.* **23**, 829). V. F. HARRINGTON

Complex thiocyanates of quadrivalent molybdenum. G. A. BARBIERI. *Atti accad. Lincei* **12**, 55–61(1930).—The thiocyanates of quadrivalent Mo, previously unknown, have been prepd. by oxidizing the pyridine as well as the hexamethylenetetramine salts $(C_5H_5N)_2H_2Mo(CNS)_6$ and $(C_6H_{12}N_4)_2H_2Mo(CNS)_6$, with $K_4Fe(CN)_6$. Both of the above salts are insol. in water; so the reaction is carried out by grinding each with $K_4Fe(CN)_6$ in a mortar in the presence of water. With the C_5H_5N salt, an intense blue-violet solid results, while with the tetramine, a green-violet solid results. The analyses indicate that the products are $(C_5H_5N)_2H_2Mo(CNS)_6$ and $(C_6H_{12}N_4)_2H_2Mo(CNS)_6$. To prove that quadrivalent Mo is present, a method was developed by B.; the method depended on the observation that any Mo salt can be oxidized to Mo^{VI} by a cold soln of ammoniacal $Fe(CN)_6^{III}$, this being in turn reduced to $Fe(CN)_6^{II}$. The equivs. of $Fe(CN)_6^{III}$ reduced are a measure of the oxidation. The Mo was thus found to be

quadrivalent. The estn. of $Fe^{II}(CN)_6$ and $Fe^{III}(CN)_6$ in solns. of CN and SCN as well as halogens has already been worked out by B. (*C. A.* **24**, 4724). A. W. CONTIERI

Studies on some complex chromiselenates. I. P. B. SARKAR AND S. N. BHATTACHARYA. *J. Indian Chem. Soc.* **7**, 765–9(1930).—The close analogy between the properties of complex chromisulfates and complex chromiselenates is discussed. The methods of prepn. and analysis of chromoselenic acid, $H[Cr(SeO_4)_2]$, chromoselenomonosulfuric acid, $H_2[Cr_2(SO_4)(SeO_4)_3]$, chromoselenodisulfuric acid, $H_4[Cr_2(SO_4)_2(SeO_4)_3]$, chromoselenotrisulfuric acid, $H_6[Cr_2(SeO_4)_3(SO_4)_3]$, and the corresponding K salts are outlined. Na chromoselenic alum is described. L. L. QUILL

The system MgO–FeO–Fe_2O_3 in air at one atmosphere (ROBERTS, MERWIN) **8.**

WOLF, LUDWIG: **Grundzüge der anorganischen Chemie.** 2nd ed., revised Leipzig: F. Deuticke. 230 pp. M. 6; bound, M. 8.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Differential potentiometric titration. IV. (a) Adaptation of the method to the use of hydrogen electrodes. (b) Test of standards for precise acidimetry. DUNCAN A. MACINNES AND IRVING A. COWPERTHWAITE. *J. Am. Chem. Soc.* **53**, 555–62(1931).—The way in which the differential electrometric method of titration can be adapted to the use of H electrodes is described in detail and 2 cuts show the necessary app. Expts. with electrometric detn. of the end point by the method described, using const.-boiling HCl, K acid phthalate and benzoic acid as standards, gave results agreeing to within 0.01% or better. W. T. H.

Improved apparatus and method for the analysis of gas mixtures by combustion and absorption. MARTIN SHEPHERD. *Bur. Standards J. Research* **6**, 121–67(1931).—The app. described is of the Orsat type but contains many improvements. A buret is provided which prevents parallax errors; a device gives good illumination; a manometer-compensator is provided which is compact and less fragile than the usual type, the pressure balance being obtained by electric contact; a special stopcock insures accuracy; a water jacket is provided which does not require a very large rubber stopper; a distributor, or manifold, eliminates much capillary dead space; the absorption pipet works very rapidly, the combustion pipet eliminates the undesirable features of the common type; a sampling pipet is designed to permit manipulation without danger of contamination; sources of leakage are avoided; the complete assembly is unusually convenient; the app. is supported entirely by metal; the assembly and replacement of parts is easily accomplished. Several procedures are given for making technical and accurate gas analyses. The app. was designed for the purpose of getting more accurate results and saving time. The original paper must be consulted for details. W. T. H.

Quantitative study of the boric acid-alcohol flame test. W. STAHL. *Acta Univ. Latviensis Kim. Fakultat. Serija* **1**, No. 13-17(in German 399-400)(in Lettish 369-99)(1930).—The H_3BO_3 esters give the green flame test when the reacting components are at about 100° below the b. p. of the EtOH or MeOH used. With rise in temp. the effect is increased. The concd. H_2SO_4 used in the test serves not only to liberate H_3BO_3 and remove H_2O but also has an effect upon the flame. The color can be estd. with the aid of a colorimetric scale. The best flame test is obtained when the temp. is not far from the b. p. of the alc. and the best reaction mixt. is 5 vol. MeOH to 1 vol. concd H_2SO_4. The dimensions of the app. have an effect upon the smallest quantity of H_3BO_3 that can be found but with the micro app. described in this paper, as little as 0.005 mg. H_3BO_3 can be detected. As much as 3% of water in the MeOH does not have any noticeable effect. W. T. H.

Spectrum analysis in assaying. A. A. FITCH. *Mining Mag.* **43**, 81–5(1930).—Procedure is outlined for the most valuable types of applications: (1) Qualitative test for a particular metal. This is recommended for sorting steel scrap. (2) Qualitative test for all metals present. This is valuable esp. in complete assays of Pt metals and rare-earth concentrates. (3) Approx. quantitative analysis—done by comparison with standard spectra. (4) More accurate quantitative detn.—done by measurement of intensity of lines by spectrophotometry. The accuracy of the method is about 5%. It is suitable for rapid analysis of steels where highest accuracy is not required.

Numerous other applications are suggested, the greatest advantage being rapidity. A. BUTTS

Role of silica in the decomposition of fluorides. P. FUCHS. *Chem. Erde* 5, 99–105 (1930).—In the Berzelius method for the decompn. of insol. fluorides, *e. g.*, fluorspar, by fusion with alkali carbonate mixed with SiO_2, the part played by the SiO_2 is in the formation of a double NaCa silicate. The carbonate and SiO_2 may be fused beforehand to avoid frothing in the actual analysis; the addn. of NaOH is advantageous. B. C. A.

Cobaltic sulfate as an oxidizing agent. SHERLOCK SWANN, JR., AND THEODORE S. XANTHAKOS. *J. Am. Chem. Soc.* 53, 400–4(1931).—$Co_2(SO_4)_3$ is best used as an analytical reagent for the quant. oxidation of certain org. compds. to CO_2. An electrolytic method is described for prepn of the reagent. B. A. SOULE

The use of hydrogen sulfide and ammonium sulfide in analytical laboratories. E. CATTELAIN *J. pharm chim.* [8], 12, 367–76(1930).—Useful practical notes on the prepn. of these reagents and precautions to be taken in pptg., washing and weighing the various metal sulfides are given. Their analytical properties are summarized in 5 tables. S. WALDBOTT

Organic reagents in qualitative inorganic analysis. B. TOUGARINOFF. *Ann. Soc. Sci. Bruxelles* 50, Ser. B, 145–246(1930). The paper contains data concerning the use of about 100 different org. compds which have been recommended for the qual testing of inorg materials A bibliography is given, also a statement concerning the nature of each reaction, the method of applying the test and the sensibility. Numerous tests for the following cations are described: Al, Sb, Cu, Bi, Ba, Cd, Ca, Cr, Co, Sn, Fe, Mg, Hg, Mn, Ni, Pb, Sr and Zn No less than 24 different tests are given for Cu, 13 for Fe, 10 for Mg, etc. After giving these data, the latter part of the paper states the results obtained in trying out some 15 of these tests the alizarin test for Al, the rhodamine B, pyrogallol, benzidine and urotropine tests for Sb, the urotropine dimethyglyoxime and rhodamine B tests for Bi, the antipyrine and K xanthogenate tests for Co, the alizarin test for Mg, the benzidine test for Pb, the diphenylamine diethylaniline and orange IV tests for Zn The sensitiveness and specificity of each test are discussed critically and the 3 tests for Zn, the alizarin test for Al, the rhodamine B test for Sb and the dimethylglyoxime test for Bi are recommended especially W T H

Determination of small quantities of hydrogen and oxygen in active charcoal. ALFRED STOCK, HERMANN LUX AND JOHN W R KAYNER *Z anorg allgem Chem* 195, 158–63(1931) Degasify the charcoal and then burn it with a known vol of O Condense the resulting water, and from the quantity obtained, compute the H content Then, since the vol of CO_2 is equiv to that of the O_2, the residual gas, corrected for the O_2 in the water, gives the vol of O_2 from the O in the original coal An app is shown which is suitable for the analysis and the method is described in detail. W. T H

Rapid colorimetric estimation of potassium. EARLE R CALEY. *J. Am. Chem. Soc.* 53, 539–45(1931); cf. C. A. 24, 2081. Dissolve in 1 cc of water the dry residue from a soln. and add 7.5 cc of a satd soln of picric acid in 95% alc After a ppt begins to form in the stirred soln, allow the mixt. to stand at 20° for 45 min with stirring at 5-min. intervals. Filter and wash the ppt with ether. Dissolve the ppt. and compare the color with that obtained similarly from known quantities of K. W. T. H

Determination of magnesium in portland cement and similar materials by the use of 8-hydroxyquinoline. J. C. REDMOND AND H. A. BRIGHT. *Bur. Standards J. Research* 6, 113–20(1931). Digest 0.5 g of cement with 20 ml of 6 *N* HCl, heating gently Dil. to 150 ml. and add Me red indicator and concd NH_4OH until the soln is distinctly yellow Boil 1–2 min., allow the ppt to settle and filter promptly To the filtrate, add 1 ml. of concd NH_4OH and 25 ml of 4% NH_4 oxalate soln Boil 2–3 min., digest on the water bath for 30–60 min., filter and wash 5–6 times with hot water. Heat the filtrate (about 350 ml.) to 60–70° and add 20 ml of reagent (25 g. 8-hydroxyquinoline dissolved in 60 ml. of glacial AcOH and dild to 2 l with cold water) and 4 ml. of concd NH_4OH per 100 ml. of soln. Stir mechanically for 10–15 min. Filter and wash the Mg ppt. with hot 0.37 *N* NH_4OH. Dissolve the ppt. in 50–75 ml. of hot 1.2 *N* HCl, dil. to 200 ml., add 15 ml. of concd. HCl, cool to 25° and det. the hydroxyquinoline content by the KBr-$KBrO_3$ method of Berg. The results obtained with standard argillaceous limestone were excellent. The experienced analyst can det. MgO within 2 hrs. by this method. W. T. H.

Determination of magnesium as pyrophosphate. STANKO S. MIHOLIC. *Bull. Soc. Chim. Yoy. Yougoslavie* 1, Pt. II 16–24(1930). –To avoid the error due to rapid heat-

ing of $MgNH_4PO_4$, it is recommended to use Jena filtering crucibles and heat the ppt. for 2 hrs. at 480° in an elec. oven. W. T. H.

Electrolytic separation of lead and antimony and its application to the determination of lead in tartar emetic. ELLA M. COLLIN AND HENRY J. S. SAND. *Analyst* **56**, 90-3(1931).—A study of the deposition potentials of Sb^{+++}, of Sb^{+++++} and of Pb^{++} in tartrate solns. showed the possibility of sepg. Pb and Sb electrolytically from such solns. The method described depends upon the oxidation of the Sb to the higher state by I_2 in the presence of HCO_3^-. Tartaric acid is added and the soln made alk. with KOH. It is then electrolyzed by a current derived from an external source or from internal electrolysis. Dissolve 5 g. of tartar emetic in water, add 3 g. of $NaHCO_3$ and oxidize the SbO^+ with KI_3 soln. Then add 4 g. KOH and 2-3 g. of tartaric acid. Dil. to 300-350 cc. and electrolyze cold, using a Pt cathode which has been coated with Cu. Rotate the anode. In 15-20 min., quantities of 1-6-3-3 mg. of Pb can be detd. accurately. Directions are given for carrying out the method by internal electrolysis with a Zn anode and a 10% KCN soln. in the anode compartment. W. T. H.

Analysis of lead peroxide and of red lead. G. BRUHNS. *Chem.-Ztg.* **55**, 50-1 (1931). Instead of using $FeSO_4$ or oxalic acid to reduce PbO_2 or Pb_3O_4 in the presence of acid, it is now recommended to use a soln. of $Fe(NO_3)_2$ and HNO_3. A suitable soln. can be prepd. by treating $FeSO_4$ soln. with an excess of $Pb(NO_3)_2$ and allowing the ppt. to settle. Add the soln. from a buret until the PbO_2 or Pb_3O_4 dissolves completely in the added HNO_3 and titrate the excess Fe with $KMnO_4$. Excellent results were obtained in the 13 analyses cited. W. T. H.

Analytical chemistry of rhenium. II. Determination of rhenium as nitron perrhenate after previous precipitation as sulfide. W. GEILMANN AND F. WEIBKE. *Z. anorg. allgem. Chem.* **195**, 289-308(1931). To ppt. Re as sulfide, the soln. should be 3-6-4-2 *N* in HCl and the current of H_2S should be continued for at least an hr. It is well to start with the soln. hot and pass the gas for 2-2.5 hrs. while the soln. is cooling. Wash the ppt. with 0.3 *N* HCl which has been satd. with H_2S. Treat the sulfide with 3-5 cc. of 5% NaOH and with 2-3 cc. of perhydrol which converts the S to SO_4^{--} and the Re to ReO_4^-. After removing the excess peroxide by boiling, neutralize with 2 *N* H_2SO_4 and ppt. the hot soln. with nitron. The oxidation of the sulfide can also be accomplished by fusion with Na_2O_2 which is particularly advantageous with sulfide ppts. that have been dried and aged. Cf. *C. A.* **25**, 50. W. T. H.

Estimation of small quantities of tin. J. E. CLENNELL. *Mining Mag.* **43**, 9-13 (1930). The accuracy of the usual volumetric method of reduction of a stannic salt in HCl soln. with Fe or Ni, followed by titration with I, was tested for detg. 1 to 30 mg. of Sn. Results with the smaller amts. were shown to be unsatisfactory. A colorimetric method that gives better results for 0.1 to 1 mg. of Sn is based on the blue color given by stannous salts with $(NH_4)_2MoO_4$. Several other reducing agents give the same color, so that the Sn must first be isolated. From the HCl soln. As and Sb are pptd. by Cu, which in turn is pptd. by Pb. The Sn is then pptd. on Zn from a slightly acid soln. This is dissolved in HCl and the soln. reduced by boiling with Pb foil. It is then poured into 10 cc. of alk. molybdate soln. (about 1% $(NH_4)_2MoO_4$ with 2% NaOH). A. BUTTS

The lead reduction method for the determination of tin and the interference with it by copper and antimony. S. G. CLARKE. *Analyst* **56**, 82-89(1931).—The reduction of Sn from the quadrivalent to the bivalent conditions can be accomplished by boiling the soln. (1.2 *N* in HCl) with a strip of Pb foil for 1.5 hrs. in an atm. of CO_2. The reduced soln. may be cooled and titrated with I_2, the results being accurate if air is kept out by the stream of CO_2 during the entire expt. If, however, Cu is present in the soln., the results are low and the error is proportional to the Cu content. When Sb is present, the error is less but distinctly noticeable. The conclusion is drawn that the method should be applied only after the removal of Cu and Sb if accurate results are desired. W. T. H.

The analysis of crude platinum and palladium. W. P. HORNE. *Mining Mag.* **43**, 278-80(1930). Detailed procedure is given for analysis of material contg. 98 to 99.85% Pt or Pd, with detn. of the impurities and other precious metals present, as well as the Pt or Pd. A. BUTTS

Rapid determination of zinc in brass. G. BRUHNS. *Chem.-Ztg.* **55**, 41(1931). KARL ALTMANNSBERGER. *Ibid* 41-2.—Thews and Harbison (*C. A.* **25**, 661) recommended the approx. detn. of Zn by the color of the metal drillings, stating that more accurate results can be obtained by detg. the Cu and estg. the Zn by difference. B. points out that the KCNS-KI method is excellent for the rapid volumetric detn. of the Cu, and A. that the conventional iodide method gives excellent results. W. T. H.

The analysis of wolframite and scheelite. C. STANSFIELD HITCHEN. *Mining Mag.* **43**, 208-20(1930).—The effect of W on the sepn. of other elements makes a complete ore analysis difficult, and esp. so in presence of Ta, Cb, Sn and Ti. The occurrence and mineralogy of W are described and analytical methods discussed at length, with recommendations and a diagrammatic scheme for procedure. A bibliography is also given. A. BUTTS

Sulfur-print tests. L. E. BENSON. *Electrician* **106**, 4–5(1931).—The value of the S-print test, its simple operation and its sensitiveness are pointed out. The test can be applied to practically all steels of importance except when the Cr content is high, as in stainless steels and some non-magnetic steels. W. H. BOYNTON

Rapid determination of carbon dioxide in carbonates. THEODOR HECZKO. *Z. angew. Chem.* **44**, 85-6(1931).—Place the sample in a boat, cover with V_2O_5, heat in a current of O_2 to 1200° and collect the resulting gas. After measuring the volume in a gas buret, absorb the CO_2 in KOH; the diminution in vol. gives the CO_2. W. T. H.

Improved method for determining carbon dioxide. C. A. JACOBSON AND JOHN W. HAUGHT. *Bull. West Va. Univ. Sci. Assoc.* **2**, No. 4, 8–13(1930); cf. *C. A.* **24**, 4237. – The carbonate is decompd. with 20 cc. of 15% $HClO_4$, the evolved gas escapes through a condenser into a bubble tube, is dried with "dehydrite" and the CO_2 absorbed in ascarite. The results obtained in over 40 expts. are reported. W. T. H.

Assay of calcium carbide and Czechoslovakian standards. R. VONDRAČEK *Chem. Listy* **24**, 193-7(1930).—The provisional Czechoslovakian standards make use of a modified Caro's app. for the assay of CaC_2, this method is not exact, and an app giving more accurate results is described. The yield of C_2H_2 should not be given in cc. of moist gas, as the Gay-Lussac formula is only applicable to dry gases. The exptl error in the assay of carbide should not exceed 2%. B. C. A.

Determination of free acidity of chrome alum. J. R. GUASCH. *Afinidad* **10**, 157-8(1930); *Chimie & industrie* **24**, 1082(1930). The various alums (K, Fe, Cr) obtained as by-products in several mfg. processes cannot generally be used directly on account of their free H_2SO_4 content, which must be neutralized, and therefore detd., before use. Bellucci and Lucchesi's method, which is used in $Al_2(SO_4)_3$ plants, is based on the colorimetric reaction of hydrolyzed salts with methyl orange, and cannot be used for Cr alum on account of the color of the Cr ion. A suitable method is based on the insoly. of Cr alum in alc. A 15% soln. of the alum is treated with 3.5 times its vol. of 96% alc., allowed to stand 24 hrs., filtered and titrated with 0.2 *N* K_2CO_3 in the presence of phenolphthalein. A. PAPINEAU-COUTURE

Colorimetric determination of the sulfate ion in water, coal, etc. P. GUARNIERI *Ind. ital. cons. alim* **3**, 161(1930). *Chimie & industrie* **24**, 814.—The method consists in treating 100 cc. of the water at the boiling temp. with an HCl soln. of $BaCrO_4$, neutralizing with $CaCO_3$, filtering the ppt. and comparing the color of the filtrate with that of standards. A. P. C.

Determination of iodide in the presence of other halides. HUGO DITZ *Z. anorg. allgem. Chem.* **194**, 147-50(1930). The statement of Gorbachev and Kasatkina (*C. A.* **24**, 4240) that IO_3^- cannot be used as an oxidizing agent for the detn. of I^- in the presence of other halogens is refuted. Early expts. of Ditz and Margosches (1901) led to the conclusion that it is possible to base a simple and exact process for the detn. of I^- with Br^- and Cl^- on the different behavior of the halides toward IO_3^- with definite H^+ concns. Further investigations (1904) led to a process for the detn. of I^- by which a definite excess of KIO_3 soln. and a definite amt. of H_2SO_4 are added to the I^- soln. The liberated I is sepd. and titrated with $Na_2S_2O_3$ soln. A. S. S.

A new microdetermination of the calcium ion and of phosphorus. M. MOUSSERON AND (MLLE.) N. BUISSON. *Bull. pharm. Sud-Est; Schweiz. Apoth. Ztg.* **68**, 654-8(1930); cf. *C. A.* **24**, 4731.—To det. both Ca^{++} and PO_4^{---} in a single sample, ppt. the P as $FePO_4$ by adding $FeCl_3$ and carrying out a basic acetate sepn. Dissolve the ppt. in HNO_3 and det. P by the molybdate method. Take the filtrate and ppt. Ca with Na tungstate. S. WALDBOTT

Determination of small quantities of volatile organic acids in sulfuric acid solutions. D. N. CRAIG. *Bur. Standards J. Research* **6**, 169-92(1931). –In the study of the corrosive effect of various org. substances on the plates of Pb accumulators, it was found that sometimes small quantities of AcOH in the electrolyte caused corrosion of the + plates. In this connection, as well as in the study of the adequacy of treatment of wood separators, it became necessary to det. small quantities of AcOH in the presence of 30–40% H_2SO_4. It was also desirable to test for formic acid. Fifty ml. samples of the acid were treated with sufficient 20% NaOH soln. to neutralize about 35 ml.

of the acid. The mixt. was carefully evapd. to dryness by a bath kept at 65–75° until most of the liquid was evapd. and then heated about 10° higher. Water was added and the evapn. repeated to make certain that all volatile acid was removed. The app. used for the distn. was ingeniously devised so that there was no danger of any spattered acid getting into the distillate. The total acidity of the distillate was detd. The neutralized soln. was then treated with Na_2CO_3 and $KMnO_4$ to destroy the formic acid and then another distn. with H_2SO_4 served to remove AcOH alone. The acidity of the distillates was detd. by electrometric titration using the differential method of MacInnis and Dole, somewhat modified. The values obtained were also compared with those obtained by indicator titrations using phenolphthalein. The potentiometric method was found excellent for titration solns. of low acidity as obtained from electrolytes contg. about 0.1% of AcOH or formic acid in 40% H_2SO_4. W. T. H.

Microdetermination of urea by Nicloux and Welter's method. R. Guillemet and P. Golaz. *Compt. rend. soc. biol.* **101**, 726–8(1929).—The rapidity and precision of the method are increased by pptg. the serum with Tanret's reagent, treating the filtrate with 0.2 cc. of a 5% soln. of xanthydrol in MeOH (or 1% in AcOH), and collecting the ppt. on a Jena filter. After washing, finally with satd. alc. dixanthylcarbamide, the ppt. is dried in a current of air at 125° for 5 min. B. C. A.

A new method for the conversion of alkali sulfate to alkali chloride for use in silicate analysis (Mylius) **6**. Calorimetric method for determining silicon (King) **11B**. Density of H_2SO_4 solutions of $CuSO_4$ (Chapas, *et al.*) **18**.

8 MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Optical data for some rare minerals. T. Barth and H. Berman. *Chem. Erde* **5**, 22–42(1930).—Mention is made of various media of high n and of the dispersion method for detg. under the microscope the ns of immersed mineral particles. Optical data are given for some 30 minerals. B. C. A.

Algodonite and whitneyite. F. Machatschki. *Neues Jahrb. Mineral. Geol.*, Abt. A, Beilage Bd. **59**, 137–58(1929).—The minerals are crystallographically inhomogeneous. The regular crystals, apparently metallic Cu contg. As, have a 3.647–3.651 A. U. The hexagonal crystals contain less Cu than corresponds with the formula Cu_3As and have a 2.599, 2.598; c 4.215, 4.213 A. U., with d. 8.71, 8.72 B. C. A.

The system MgO-FeO-Fe_2O_3 in air at one atmosphere. H. S. Roberts and H. E. Merwin. *Am. J. Sci.* [5], **21**, 145–57(1931).—The system MgO-FeO-Fe_2O_3 has been investigated at temps. above 1000° on the isobar $\frac{1}{5}$ atm. O_2. In the binary system MgO-Fe_2O_3 the only compd. is MgO.Fe_2O_3 which dissociates slightly on heating and begins to melt at 1750 ± 25°. Solid soln. extends for a short distance toward MgO. In the binary system FeO-Fe_2O_3 the stable phase at temps. below 1386 ± 5° is a hematite solid soln. contg. less O than Fe_2O_3; just above 1386° the stable phase is a magnetite solid soln. contg. considerably more O than Fe_3O_4. The ternary system contains 2 solid soln. fields. The first begins at MgO below 1000° and extends with increasing temp. toward MgO.Fe_2O_3 and FeO; a liquid phase appears at 1770 ± 25°, where the solid contains Fe oxide equiv. to 73% Fe_2O_3. The second solid soln. extends with increasing temp. from MgO.Fe_2O_3 toward the Fe oxide boundary, which it reaches

at 1386 ± 5°; solid solns. of about 1% MgO in $MgO.Fe_2O_3$ are possible from 1750 to 1000° or below. ALDEN H. EMERY

The genesis of lodestone. MARK C. BANDY. *Econ. Geol.* **25**, 871–5(1930).—B. discusses recent articles by Newhouse (*C. A.* **23**, 4649) and Gruner (*C. A.* **23**, 4167), on the origin of lodestone. The theory proposed by N., that lodestone is due to a brownish oxidized magnetite, does not meet all the conditions under which it occurs naturally and is formed artificially. The theory that it is formed by the magnetic field of the earth is equally inadequate. Lightning striking outcrops of magnetite ore is suggested as a theory for the origin of lodestone. ALICE W. EPPERSON

A contribution to the study of moonstone from Ceylon and other areas and of the stability relations of the alkali feldspars. EDMONDSON SPENCER. *Mineralog. Mag.* **22**, 291–367(1930). —Moonstone feldspar from pegmatite near Ambalagoda was found to possess a microperthitic structure. The lamellas (or, ab) have sepd. mainly along the plane Δ (13.0.2) which is also the plane of schiller. A coarser but fainter perthite occurs, which sepd. at an earlier stage along the prism planes 110 and 320. Schillerized feldspars from Kandy, Burma and Colorado were found to be similar. The schiller color is dependent on the size and abundance of microperthite lamellas and is mainly due to the reflection and scattering of light at the boundaries of these. The sp. gr., optical axial angle and extinction angles are dependent on the proportions of the 2 feldspars present. The schiller color and microperthitic structure can be destroyed by heat treatment, and there is a reduction in sp. gr., optical axial angle and extinction angle. The changes appear to be due to a re-soln. of the (or, ab) members into each other to form the original (Or, Ab) phases. Structures can be developed on cleavage faces where there is little evidence of microperthite by heating with water and CO_2 under pressure, causing selective decompn. The phenomena observed on heating indicate that there are 2 solid-soln. changes, at (*a*) 900–1000° between a single solid soln. phase and the 2 (Or, Ab) phases, and (*b*) 500–700° for the (or, ab) sepn. either from the 2 (Or, Ab) phases or from one of them. Structure in the Ambalangoda microcline-microperthite indicates that the conversion to microcline evidently took place prior to the exsoln. of the microperthite and hence probably above 700°. It undergoes none of the changes in properties found for moonstone feldspar and no re-soln. takes place on heating. Microcline appears to be the stable form of K feldspar and to be incapable of holding albite in solid soln. up to temps. near its m. p. A. M. B.

Mineralogy of Western Australia. EDWARD S. SIMPSON. *J. Roy. Soc. W. Australia* **15**, 99–113(1928–29); cf. *C. A.* **24**, 3969. Descriptions and in most cases chem. analyses are given for: apatite; gray and white beryl (contg. Cs_2O 0.72 and 0.92%, resp.), cinnabar; glaucophane, siderite and corundum, manganilmenite and menaccanite; manganocolumbite, Ta_2O_5 10.48, Cb_2O_5 62.34%, resp., microlite, Ta_2O_5 77.00, Cb_2O_5 3.64; spinel; tourmaline, both schorl and dravite; and vesuvianite. W. L. HILL

Minerals from the Adamello Mountains (Trentino). C. GOTTFRIED. *Chem. Erde* **5**, 106–12(1930); cf. *C. A.* **24**, 4243. The minerals described are from marble (metamorphic limestone) at contact with tonalite. Garnet as reddish brown dodecahedra, with d. 3.512 and n_{Na} 1.7585, gave analysis I, corresponding with grossular 80.55, andradite 8.13, almandine 4.48, pyrope 6.85%. Vesuvianite as olive-green crystals with $a:c$ = 1 : 0.5391, d. 3.336, ω 1.719, ϵ 1.715, gave analysis II, agreeing with Tschermak's formula $Si_{17}Al_{10}Ca_{18}Mg_2H_6O_{72}$. X-ray rotation photographs gave a unit cell of dimensions a 22.03, c 11.89 A. U., contg. 2.3 such mols., *i. e.*, 168 O atoms. The space-group is D^4_{4h}.

	SiO_2	TiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	H_2O
I	39.66	0.46	18.77	2.52	1.92	0.07	2.06	34.79	0.07
II	37.03	0.75	16.25	3.13	1.09	0.04	2.45	36.39	2.29

II also ZnO 0.29, Na_2O 0.28, K_2O 0.03, F 0.31, total less O for F 100.15%. B. C. A.

Analytical determination of the isomorphous variation in rock-forming minerals. H. VON PHILIPSBORN. *Chem. Erde* **5**, 233–53(1930). —The powd. rock, a pyroxene granulite from Hartmannsdorf, Saxony, was sepd. into different fractions with Clerici soln. and an electromagnet. Analysis I*a* is of the heavier and darker fraction (d. 3.55–3.58, $n[= \frac{1}{2}(\alpha + \gamma)]$ 1.715) of the hypersthene and I*b* of the lighter and paler fraction (d. 3.49–3.55, n 1.706), II*a* of the heavier fraction (d. 3.40–3.42, n 1.708) and II*b* of the lighter fraction (d. 3.37–3.40, n 1.698) of the monoclinic pyroxene. Analysis III is of the heavier fraction (d. 2.69–2.71, n 1.555–1.560) of the plagioclase, correspond

ing with $Ab_{47}An_{53}$; the lightest fraction with n 1.549 corresponds with $Ab_{70}An_{30}$. Analysis IV is of the garnet (d. 3.92, n_{Na} 1.766) and V is ilmenite. From optical data on the still lighter and heavier fractions of the pyroxenes their compn. is arrived at by extrapolation. VI is the bulk compn. of the rock (d. 3.181), corresponding with hypersthene 28.53, monoclinic pyroxene 29.60, plagioclase, 32.59, orthoclase 0.44, garnet 3.31, ilmenite 4.35, magnetite 0.35, apatite 0.83%.

	SiO_2	TiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	Na_2O	K_2O	Total
I*a*	49.42	0.54	2 64	3.42	23.15	0.26	18.17	0.94	1 23	0 19	99.96

V, also insol. silicates 1.5; VI, also P_2O_5 0.36, Cr_2O_3 0.10%.

B. C. A.

Chemical formula of the zirconium pyroxenes and zirconium pectolite. W. H. ZACHARIASEN. *Norsk Geol. Tids.* 11, 216-8(1930).—From a study of analytical data obtained from the Zr pyroxenes, låvenite, wöhlerite, and hiortdahlite and the Zr pectolite, rosenbuschite, it was found that the general formula $R_4Si_2X_9$ held for all 4 minerals where R represented all cations save Si, and X the anions. This proves that the names "Zr pyroxenes" and "Zr pectolite" have no chem. justification. H. H. MOSHER

Sapphirin from Alpe Brasciadega, Val Codera, Italy. H. P. CORNELIUS AND E. DITTLER. *Neues Jahrb. Mineral. Geol.*, Abt. A, Beilage Bd. **59**, 27-64(1929). —The sapphirin, isolated by means of H_2SO_4 and HF contained SiO_2 15.19, TiO_2 0.25, Al_2O_3 61.69, FeO 4.31, MnO 0.12, CaO 0.49, MgO 16.23, H_2O+ 1.60, H_2O- 0.19%, corresponding with the formula $Mg(Fe, Mn, Ca, H_2)_{11}Al_{24}Si_5O_{57}$. B. C. A.

Isomorphous series in the tourmaline group and the genetic relationships between tourmaline and the micas. W. KUNITZ. *Chem. Erde* **4**, 208-51(1929).—Theoretical.

B. C. A.

Tourmaline group. F. MACHATSCHKI. *Chem. Erde* **4**, 455-7(1930).—A criticism of the formula of tourmaline proposed by Kunitz (preceding abstract). B. C. A.

Thuringite from Schmiedefeld, Thuringia. H. JUNG AND E. KOHLER. *Chem. Erde* **5**, 182-200(1930). Olive-green material consisting of a compact aggregate of fine scales with d. 3.187 gave on analysis: SiO_2 20.82, TiO_2 trace, Al_2O_3 17.64, Fe_2O_3 8.70, FeO 37.96, MgO 4.15, H_2O+ 10.31, H_2O- 0.07, total 99.65%. The analysis agrees with the formula $14(Fe,Mg)O.5(Al,Fe)_2O_3.12H_2O.7SiO_2$. Most of the water is expelled at about 420°, and the dehydration curve is very similar to that of kaolin. X-ray powder photographs of thuringite have been compared with those of quartz, magnetite and kaolin; some of the magnetite and kaolin lines correspond, but those of quartz are absent. Magnetite has a unit cube of edge 8.393 A. U. contg. 8 mols.

B. C. A.

Studies on the zeolites. I. General review. MAX H. HEY. *Mineralog. Mag.* 22, 422-37(1930).—A review of the general characteristics of the zeolites and their relations to other groups of minerals and to certain artificial products, preparatory to a detailed examn. of the various species. A bibliography is given. A. M. BRANT

Steatite from the Münchberg gneiss area. F. DEUBEL. *Chem. Erde* **5**, 87-95 (1930).—A new occurrence of steatite has been found near Schwarzenbach a. d. Saale on the southeast border of the Münchberg gneiss area in Bavaria. It is shown to be a replacement of quartzite, no doubt by hydrothermal action. Analysis of the material gave: SiO_2 61.95, Al_2O_3 0.87, FeO 0.57, MgO 32.16, loss on ignition 4.99, total 100.54%.

B. C. A.

Dehydration and rehydration of kaolin. P. SCHACHTSCHABEL. *Chem. Erde* **4**, 395-419(1930). —Kaolin after being heated at 400-800° is capable of taking up H_2O again. This is effected very slowly at 110°, but under pressure at 175-205° all is restored after 100 hrs. The rehydrated kaolin differs from the original material by being partly sol. in HCl, in its dehydration curve, n and x-ray pattern, but these differences become less marked after prolonged heating of the material in H_2O at 200°. B. C. A.

Halloysite from Elbingerode [Harz]. O. H. ERDMANNSDÖRFFER. *Chem. Erde* **5**, 96-8(1930).—Nodules of grayish green halloysite (analysis I) coated with white powdery material (analysis II) occur in limonite in the "Grosse Graben," which has been worked for Fe and Mn ores and pyrite. Both are optically isotropic with n = 1.515-1.528.

II gives the ratios $SiO_2:Al_2O_3:H_2O$ = 2.20:1:4.90. Between 105° and 400° very little water is lost and the material then behaves like kaolin. An x-ray powder photograph shows a few faint lines coinciding with those of kaolin. The ignited material gives no x-ray spectrum.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O	H_2O (105°)	H_2O (ign.)	Total
I	36.27	29.53	5.31	0.10	0.02	0.23	1.60	0.64	14.19	12.70	100.59
II	39.00	30 07	2 98	0.01	0.04	0.40	1.31	1 24	12.70	15.15	101.09

Also traces of P_2O_5, TiO_2, SO_3, CO_2, MnO. B. C. A.

Nontronite. W. Noll. *Chem. Erde* **5**, 373–84(1930).—Weinschenk (*Z. Kryst Min.*, **28**, 135–64(1897)) regarded nontronite as analogous to kaolin; he gave the formula as $H_4Fe_2Si_2O_9$, but very few analyses agree with such a formula. Dehydration curves and x-ray powder photographs also show no relation to kaolin. The water is "zeolitic." A new analysis of green greasy nontronite from Tachau, Bavaria, gave SiO_2 40.02, Al_2O_3 10.55, Fe_2O_3 26.16, FeO 1.37, H_2O 21.83, total 99.93%, corresponding with the ratios $R_2O_3:SiO_2:H_2O$ = 1:2.49:4.53. B. C. A

The chemical composition and crystallographic and optical properties of a Vesuvian lithidionite. Guido Carobbi. *Atti III congresso naz. chim. pura applicata* 1930, 336–7.—A blue Vesuvian lithidionite of the formula (Cu, Na_2, K_2) Si_2O_7, m. p. 780°, was sepd. into Cu-poor and Cu-rich fractions by flotation in a heavy liquid. The former contained blue monoclinic crystals with d. 2.48–2.37, $a:b:c$ = 0.4506:1:0.3997, β 114.3°. The latter had d. 2.74, was optically —, and had the plane of the optic axes perpendicular to the plane of symmetry. The n_Ds. were 1.548 and 1.574. Chem. analyses of both fractions are given J. B. Austin

Blomstrandite from Kabuland. Harald Bjørlykke. *Norsk Geol. Tids.* 11, 232–9(1930).—This deposit of possible industrial importance was found in gang chiefly composed of xenotime, orthite, feldspar, quartz and magnetite. Two cryst. forms were noted, the typical blomstrandite and a euxenite-like type. The mineral yielded upon analysis: Ta_2O_5 19.11, TiO_2 31.84, UO_2 3.78, ThO_2 1.46, rare earth oxides 35%, FeO 4.30, CaO 0.88, MgO 0.38, ignition loss 3.70%. By spectro-analysis Y, Th, Ill Cp, Yb, Tu, Er, Ho, Dy, Tb, Gd, Sm and Nd were detected. H. H. Mosher

Chemical and spectrographic investigations on an apatite in Chinese strata of recent origin. Guido Carobbi. *Atti III congresso naz. chim. pura applicata* **1930**, 338–40. A specimen of apatite from Tsingtao was examd. It was a solid soln. of fluoroapatite, chloroapatite, hydroxyapatite and oxyapatite. The crystals, which were badly formed, appeared to be uniaxial, −, with d. 3.23; ϵ = 1.628, ω = 1.630. Spectroscopic examn. showed no Ce but the presence of La, Sm, Eu, Er and Yt. A chem. analysis is given. J. B. Austin

Cupriferous melanterite from the Skouriotissa mine, Cyprus. Max H. Hey. *Mineralog. Mag.* **22**, 413–8(1930).—A cluster of large greenish blue crystals of melanterite was found in an ancient caved stope in the ore body near Lefka, Nicosia district, Cyprus. The crystal habit is unusual, being tabular on b(010). Partial analysis gave CuO 2.15%. The crystallographic measurements are given. A. M. Brant

A suspected meteoric specimen from northern Arizona. L. F. Brady. *Am. J. Sci.* [5], **21**, 173–7(1931).—The specimen analyzed: metallic Fe 37.440, Fe as FeCl 0.680, Fe as FeO 3.287, S 0.073, Si 0.432, Mn 0.120, Cl as $FeCl_2$ 1.300, P 1.110, Ni 4.040, Co 0.047, C (graphite) 46.530, combined C 2.202, O as FeO 0.943 and insoluble (mainly FeO and SiO_2) 1.796%. The outer surface resembles weathered hematite. In section it appears to be an intergrowth of cryst. Ni-Fe in a ground mass of graphite. Etched surfaces show very fine Neumann lines. Its sp. gr. is 3.7. A. H. E.

A new iron meteorite from Pojoaque, New Mexico. L. F. Brady. *Am. J. Sci.* [5], **21**, 178(1931).—The specimen is of Ni-Fe. There are several spherical inclusions of chrysolite which seem to be surrounded by a layer of kamacite. Its sp. gr. is 6.2. Alden H. Emery

New observations on the tectites of Indochina. A. Lacroix. *Compt. rend.* 191, 893–9(1930). cf. *C. A.* **23**, 2395 6.—The tectites in Indochina are widely disseminated. In order to consider the uniformity of their chemical compn., tables of results of analyses of tectites taken from widely sepd. places are given. These show very close agreement. Various theories of origin are discussed, and the only one considered not impossible is that of cosmic origin, as meteorites. Indications defending this hypothesis are cited and discussed. Alice W. Epperson

Synthetic sulfide replacement of ore minerals. James C. Ray. *Econ. Geol.* 25, 433–51(1930).—Geochem. expts. were carried on with the object of detg. the point at

which dispersion of bornite in chalcocite occurs as well as such replacement phenomena as might be induced under lab. conditions. Tabulated data are given, as are results of microscopic examn. of the repolished surfaces of the treated ore fragments. The expts. show that mixed sulfides in the presence of H_2O only can generate their own conditions to bring about changes in these sulfides without addn. of metals to the local system in which the changes are taking place. R. advances the hypothesis of "deep-seated supergene alteration" for this type of massive deep-seated bornite, and believes the principles here advanced have a general application to Cu deposits of hydrothermal origin, although the discussion is based specifically on the Butte ores. A. W. E.

The texture and origin of some banded or schistose sulfide ores. W. H. NEWHOUSE AND G. F. FLAHERTY. *Econ. Geol.* **25,** 600-20(1930).—Conclusions: Criteria of flowage and plastic deformation of an ore mass, based on apparent flow structures as seen in hand specimens, are usually unreliable. An ore mass composed in whole or in part of galena, sphalerite and chalcopyrite, which has been strongly deformed, will show in its texture that flowage has taken place unless complete recrystn. has occurred. Extent of recrystn. and size of crystals are a function of strain and compn. in the crystal and of time and temp. Unless complete recrystn. of the entire ore mass takes place, 2 generations of each mineral should be found. Quartz is an introduced mineral in schist replacement deposits, showing no preferred direction of elongation or orientation. Ores are particularly discussed occurring at Blue Hill, Me., Milan, N. H., Mandy, Manitoba and Rammelsberg, Goslar, Germany. ALICE W. EPPERSON

Pseudo-eutectic textures. G. M. SCHWARTZ AND CHARLES F. PARK, JR. *Econ. Geol.* **25,** 658-63(1930).—S. and P. discuss Lindgren's paper (*C. A.* **25,** 265) and describe a specimen of ore contg. covellite intergrowths, which furnishes addnl. proof that graphic intergrowths may form by replacement. It is considered that pseudo-eutectic textures develop by replacement, even if supergene, and they may also develop by more or less contemporaneous crystn. as in ilmenite and silicates, though ilmenite could not form a eutectic with several minerals in the same rock. It is possible for the texture to develop in hard minerals, but it is relatively uncommon and has not been observed except in gabbro and titaniferous magnetites. A. W. E.

A colloidal origin of some of the Kennecott ore minerals. S. G. LASKY. *Econ. Geol.* **25,** 737-57(1930).—The sulfides that make up Kennecott ore bodies were transported in highly dispersed condition and were flocculated on reaching such an ideal flocculating agent as limestone. Alumina along thin gouge seams also served to flocculate sulfides as well as to dam back the solns. Chalcocite and S were always present. The chalcocite, in addn. to the covellite that it was able to dissolve from the surrounding material at high temp., contained in soln. also a certain amt. of covellite formed by reaction with excess S, which at this stage was present in relatively small quantity. With lowering of the temp., the covellite tended to unmix and did so in part until equil. was reached. The equil. pt. lies apparently above 8% CuS A. W. E.

The incipient oxidation of galena. ALFRED L. ANDERSON. *Econ. Geol.* **25,** 528-42 (1930).—Study of incipient states of alteration of galena indicates it to be more generally oxidized by air-water processes than by solns. of ferric sulfate. Much of the limonite represents a later addn. from external sources. The first product obtained by oxidation of galena is always anglesite. With admixt. of pyrite and chalcopyrite, the reactions become more complex. Because of formation of electrolytic cells between various sulfides in contact with the oxidizing solns., the attack on galena is greatly aided, while the oxidation of pyrite or chalcopyrite is retarded. On this basis galena oxidizes earlier and with more ease than most other sulfides, except sphalerite. Galena remains in the oxidized croppings only because the coating of insol. alteration products prevents ready access by fresh oxidizing solns. Covellite is a common but not abundant mineral formed by replacement of galena. Four main types of structures may be recognized: (1) regular borders, (2) botryoidal structures, (3) stranded borders and (4) platy structures, each referring to the relation the covellite bears to the galena. ALICE W. EPPERSON

Limonite types derived from bornite and tetrahedrite. ROLAND BLANCHARD AND P. F. BOSWELL. *Econ. Geol.* **25,** 557-80(1930).—Neither bornite nor tetrahedrite contains sufficient S to dissolve itself completely. Field evidence has not established definitely the proportions of pyrite needed to effect complete oxidation of bornite and tetrahedrite in nature. Hydrolysis of $Fe_2(SO_4)_3$ during oxidation liberates acid and may reduce below the theoretical ratio the pyrite needed for complete oxidation of bornite and tetrahedrite. Field evidence shows that an overwhelming proportion of pyrite is needed to prevent formation of indigenous limonite after bornite, and such proportion is not usual. Five limonite types derived from oxidation of bornite have

been identified and described, a triangular boxwork being most distinctive. Leached outcrops derived from bornite generally carry a "relief" limonite—a characteristic product, orange colored, with soft texture on fresh surfaces. Two limonite types derived from oxidation of tetrahedrite have been identified and described. That called contour boxwork is more distinctive. Leached outcrops from tetrahedrite usually carry local incrustations of Sb oxides that assist in identification. A. W. E.

A mother lode gold ore. CARLTON D. HULIN. *Econ. Geol.* **25**, 348–55(1930).—H. describes specimens from the Kennedy Mine, one of the largest of the Au mines operating on the Mother Lode, in Amador County, Cal. The relative degree of favorability of the several host minerals for Au as observed in these ores is: chalcopyrite, pyrite, galena, apatite, carbonates; pyrite, sphalerite; and quartz, the first 5 minerals are about equally favorable, and quartz is the least favorable. A. W. E.

Geology of the Panamint silver district, California. F. MAC MURPHY. *Econ Geol.* **25**, 305–25(1930).—The paper includes a history of mining in the district, its location and topography, a description of the rocks and their structure, and a discussion of the ore deposits. The occurrence of numerous clean-cut Ag-bearing quartz veins is described. They outcrop in limestone, schist or slate, but those in limestone are more numerous and persistent. The principal and almost exclusive vein filling is milk white, sometimes glassy, quartz of coarsely crystl. massive texture. Ag is almost wholly contained chemically bound in tetrahedrite, the principal sulfide mineral. Oxidation and supergene enrichment products are not abundant in the ores, but the following minerals have been identified: malachite, azurite, anglesite cerusite, smithsonite, bindheimite, cerargyrite, stromeyerite, chalcocite and covellite. The deposits are classified as those formed at intermediate depths and suggest a genetic relationship with an intrusion of granite porphyry. An unusual vein in the district carries, in order of deposition, pyrite, quartz, pyrrhotite, chalcopyrite, marcasite and siderite, the latter overlapping with marcasite and chalcopyrite. ALICE W. EPPERSON

Observations on secondary copper and silver sulfides in the Broken Hill Lode. F. L. STILLWELL. *Proc. Australasian Inst. Mining and Met.* No. **67**, 187–219(1927); No. **77**, 71–9(1930).—The primary ore (apart from gang) consists essentially of sphalerite and galena with minor amts. of arsenopyrite accompanied by a Ni-Co-Sb mineral, chalcopyrite, pyrrhotite and cubanite, chalcostibite and tetrahedrite, meneghinite, dyscrasite, pyrargyrite and berthierite. The oxidized zone consists of a manganiferous ironstone capping covering large masses of cerussite frequently rich in oxidized Ag and Cu minerals. Zn salts from the primary sulfide ore have been largely removed in soln. The abundance of cerussite is partly due to the abundance in the meteoric H_2O of carbonates derived from the primary calcite ore. Only minor amts. of anglesite resulted. The surface waters contained small quantities of phosphate, derived from apatite, which converted small quantities of the sulfate or carbonate into pyromorphite or Pb phosphate. At varying depths the sulfides appear. The secondary sulfides including Ag and Cu occur as coatings resembling soot on the primary. The secondary sulfides have been partially oxidized as denudation has progressed. A. H. E.

The Engels copper deposits, California. CLARENCE N. FENNER. *Econ. Geol.* **25**, 420–5(1930).—The article by Knopf and Anderson (*C. A.* **25**, 265) is discussed. The authors' statements in favor of gaseous transfer of mineral matter are approved, and their discussion is supplemented. ALICE W. EPPERSON

The ores of the northern Rhodesia copper belt. ALAN M. BATEMAN. *Econ. Geol.* **25**, 365–415(1930).—This belt will constitute the greatest Cu mining center of the world. Production and important mines are named. The region is a peneplain 4000 ft. high. The rocks consist of an old pre-mineral basement complex unconformably overlaid by ore-contg. Roan series, probably of pre-Cambrian age, intruded by younger granites and basic intrusives, the granites being the probable source of the Cu. The ore deposits consist of beds of the Roan series uniformly metallized with specks of CuS. Ores are largely sulfide, and oxidation extends hundreds of ft. below the water level. Chalcocite is the most important sulfide, followed by bornite and chalcopyrite. Linnaeite is not uncommon and pyrite is rare. Eight types of chalcocite intergrowth are described and discussed, the conclusion being that the chalcocite is in part hypogene and in part supergene. Sulfides have been introduced after consolidation and folding of the rocks and have clearly replaced the rock silicates. Localization of the ore minerals in the sediments was probably due to the superior permeability of the ore beds. This Cu belt constitutes a great metallogenetic province of Cu mineralization. It is linked with the adjacent Katanga Cu region by similar features of geology and ores and the common occurrence of the rare mineral linnaeite. A. W. E.

The correlation of the ore-bearing sediments of the Katanga and Rhodesian copper

belt. ANTON GRAY. *Econ. Geol.* **25**, 783–804(1930); cf. preceding abstract.—The principal Cu deposits of the Katanga and Rhodesia occur in the lower series of the System of the Katanga, known locally by various names. In view of the fact that these rocks were first studied in the Katanga, where the ore-bearing beds were called the Série des Mines, this name has been applied by G. to the rocks over the entire Cu belt. The sulfide ore bodies of Rhodesia are found near the base of the Serie des Mines. They lie stratigraphically below the oxidized ores of the Katanga, which are found in the dolomites of the upper Roan group, and to a lesser extent in the M'Washia. No evidence of unconformity has been found between the Série des Mines and the Kundelungu series, and it is considered that these beds should be grouped together under the name of the Katanga system, as proposed by Van Doorninck. A geologic map is included. ALICE W. EPPERSON

Some remarks on the metallogenesis of the copper beds of Katanga and northern Rhodesia. ANDRÉ DEMAY. *Rev. univ. mines* **4**, 38–46(1930); cf. preceding abstract.—The upper part of the Cu-bearing beds of Katanga are chiefly replacement deposits; impregnation predominates in the lower part; most beds are highly mineralized but "spotty." In Northern Rhodesia impregnation plays the principal part in the enrichment of the sediments, which are less highly mineralized but more uniform. Although the ores now being mined in Katanga are almost exclusively carbonates or oxides, the primary mineralization was undoubtedly in the form of sulfides. In Rhodesian beds, below the superficial zone of oxidation, the principal zone contains Cu sulfides. In Katanga, Fe, Mn, Co, especially Pb, Zn and even U and Ra, mined in a particular bed, together with Cu, constitute an indisputable metallogenic association. In northern Rhodesia the Cu veins are related to an intrusion of granite that penetrates the lower beds of the Roan series. In Katanga there is no direct proof of an igneous vein having affected the beds, although there are some indications that the Cu veins may have been influenced by acid magma C. W. OWINGS

The Sherritt-Gordon copper-zinc deposit, northern Manitoba. E. L. BRUCE. *Econ. Geol.* **25**, 868–70(1930). B. discusses the communication by J. F. Wright, (*C. A.* **25**, 1186) regarding B.'s paper (*C. A.* **23**, 4910). B. explains some apparent disagreements in the 2 papers, gives some addnl. data and states that in the main his statements and those of Wright agree ALICE W. EPPERSON

Spectrum analysis of Mansfeld copper shale. A. CISSARZ. *Chem. Erde* **5**, 48–75 (1930). To the long list of elements previously detected by ordinary analytical methods the following are now added: Sn, W, Pt, Ir, Pd and Yt, bringing the total up to 42. B. C. A.

Lead-zinc and pyrites ores of the Deutsch-Bleischarley mine, Upper Silesia. H. SCHNEIDERHÖHN. *Chem. Erde* **5**, 385–95(1930). These ores are known to contain As, they were examd. by the metallographic method for As minerals. In the Pb-Zn ore, shelly blende surrounds cores of galena and jordanite ($Pb_4As_2S_7$), but in the pyrites ore, consisting of a mixt. of pyrite, marcasite and shelly blende, no As mineral could be detected. Chem. tests showed that much As is present in the pure pyrite (no doubt in isomorphous mixt.) and only traces in the marcasite and blende. B. C. A.

Microscopic and spectroscopic investigation of the platinum-bearing rocks of the Bushveld igneous complex (Transvaal). H. SCHNEIDERHÖHN. *Chem. Erde* **4**, 252–86 (1929). A description is given of the rocks and assocd. ore minerals from the Rustenburg, Potgietersrust and Lydenburg districts, together with an account of the genesis of the deposits. In the pegmatites and contact metamorphic zone sperrylite and stibiopalladinite occur, whereas in the unaltered intrusive rocks the Pt metals are entirely present in the form of platiniferous sulfides of other metals, free Pt, Pd and Au are encountered only as secondary occurrences in the weathered rocks. Investigation of the minerals by means of the quartz spectrograph showed that the Pt metals occurred solely in the pyrrhotite, pentlandite and nickeliferous pyrite, the greatest quantity being present in the oldest minerals. Pt and Pd are present in practically equal amts., Ir, Rh and Ru occur to the extent of 1–10% of the Pt present, while Os is present in traces only B. C. A.

Hydrothermal oxidation and leaching experiments; their bearing on the origin of Lake Superior hematite-limonite ores. I. JOHN W. GRUNER. *Econ. Geol.* **25**, 697–719(1930).—G. has previously suggested that hematite ores of the Soudan formation of the Vermillion range had been leached of SiO_2 and oxidized by hot ascending waters from a large basic magma, and new expts. support the hydrothermal hypothesis and its extension to other districts of the Lake Superior region. Leaching of SiO_2 from the Fe formation is discussed, and expts. on soln. of SiO_2 in hot H_2O and on oxi-

dation of minerals contg. Fe^{++} are described. The SiO_2 was found to be very sol., and tables are given showing the solubilities of different minerals, SiO_2 from gabbro being found less sol. than quartz. It was found that the oxidation of ferrous minerals by water at high temp. begins at or below 200°. The expts. and methods used are described in detail. II. *Ibid* 837–67.—Expts. show that SiO_2 from SiO_2 gel, chalcedony, and greenalite taconite is sol. to an extraordinary extent in water at temps. from 200 to 300°. The soly., except of SiO_2 from gabbro, is many times as great at 200° as at room temp. Oxidation of Fe^{++} in minerals takes place in hot H_2O or steam in the absence of air at temps. as low as 160° provided the H given off in the decompn. can escape. Siderite is oxidized to magnetite, and magnetite to hematite. Expts. support the hypothesis that Lake Superior hematite-limonite ores were oxidized and leached hydrothermally. These ores have similar counterparts in the leached ores of South Africa. Arguments supporting the weathering hypothesis and G.'s hypothesis are discussed and the latter is upheld. ALICE W. EPPERSON

The iron deposits of the Sierra de Imataca, Venezuela. ERNEST F. BURCHARD. *Econ. Geol.* **25**, 549–50(1930).—A paper by Zuloaga on Pao Fe ore deposits is discussed in connection with one by B. (*A. I. M. M. E. Tech. Pub.* **295**, Jan., 1930). Similarities and dissimilarities in the ores of the 2 regions are pointed out. A. W. E.

Graphic intergrowth of niccolite and chalcopyrite, Worthington Mine, Sudbury. CARL LAUSEN. *Econ. Geol.* **25**, 356–64(1930).—The general geology of the region and the ore deposits are described, and the origin of the graphic texture and sequence in the deposition of the ores is discussed. The mineralization is described as taking place in 3 stages: the 1st was a high temp. hydrothermal stage, producing magnetite, pyrrhotite, pentlandite, chalcopyrite; the 2nd and 3rd were moderate temp. hydrothermal stages, producing resp. gersdorffite, maucherite, niccolite-chalcopyrite intergrowths and pyrite, sphalerite and galena. ALICE W. EPPERSON

A qualitative and quantitative determination of the ores of Cobalt, Ont. I. ELLIS THOMSON. *Econ. Geol.* **25**, 470–505(1930).—Methods of analysis are given, and development of new etching reagents is described. Geology of the region is discussed, and detailed descriptions are given of specimens from Mining Corporation, Nipissing and O'Brien Mines. The old mineralogical title of smaltite-chloanthite for the hard white mineral associates of the native Ag and niccolite of this region is no longer applicable, these 2 minerals being exceeded in rarity only by the Ni mineral gersdorffite. Cobaltite is much the commonest of these minerals. Common structures are noted for the 9 minerals, listed in order of prevalence as follows: cobaltite, arsenopyrite, safflorite, skutterudite, rammelsbergite, loellingite, smaltite, chloanthite, gersdorffite. II. *Ibid* 627–52.—Eight new microchem. reagents have been developed for differentiation of the 9 hard white As minerals which are common in this district. Crystal habits, modes of occurrence, interrelationships and assocns. with Ag of each of these minerals are discussed. Relative abundance of the common minerals is given; smaltite and chloanthite are placed among the rarer minerals of the group with cobaltite at the top of the list. Relation between quant. proportions of the other common minerals of this district and their proximity to the diabase sill is worked out and compared to a similar relation for native Ag. It appears that larger quantities of assocd. arsenopyrite, cobaltite, loellingite, rammelsbergite or skutterudite have been favorable to the deposition of native Ag, while niccolite, tetrahedrite and safflorite in larger quantities are inimical to it. The occurrence of rarer minerals is recorded as observed by other investigators. Details of ore genesis, as outlined by previous observers, are amplified to include the occurrence of such minerals as safflorite and marcasite, which are new for the district, and to fit the commoner occurrence of other minerals which were heretofore considered rare. ALICE W. EPPERSON

A qualitative and quantitative determination of the ores of Cobalt, Ont. M. N SHORT. *Econ. Geol.* **25**, 764–71(1930); cf. preceding abstract.—The work of Thomson is discussed at length, and S. makes suggestions, giving his own methods of detn of the hard arsenides. ALICE W EPPERSON

Origin of chromite deposits. F. E. KEEP. *Econ. Geol.* **25**, 425–6(1930); cf. *C. A* **25**, 899.—The paper of Fisher (*C. A.* **24**, 1319) is discussed. K. agrees with F. as to the possible cause of the chromite in the Great Dyke, but disagrees with the statement that the Great Dyke is younger than the rocks of the Bushveld Complex and gives evidence that the 2 intrusions were more or less contemporaneous. A. W. E.

The chrome deposits of Umvukwes district. F. E. KEEP. *S. African Mining and Eng. J.* **41**, Pt. II, 105–6(1930).—The chrome ore occurs in seams in serpentinized enstatite-olivine-rock and in websterite. The ore was formed by magmatic segregation.

The seams are expected to extend to some depth without change. The uses of chrome ore are discussed. ALDEN H. EMERY

Supergene cassiterite in tin veins. FRIEDRICH AHLFELD. *Econ. Geol.* **25**, 546–8 (1930).—The paper by Singewald (*C. A.* **25**, 899) is discussed. Results of investigations in Bolivia are given. Meteoric waters are not capable of dissolving cassiterite since they (in Bolivia) are always acid. Alk. surface waters are not present in Bolivia. ALICE W. EPPERSON

Supergene cassiterite in tin veins. J. B. SCRIVENOR. *Econ. Geol.* **25**, 663–4 (1930); cf. preceding abstract.—The citation of bony tissue replaced by cassiterite is thought to refer to certain Cornish stags' horns which were said to be impregnated with SnO_2, but which were found by the writer to contain no Sn, but to have grains of quartz in cavities of the bone, evidently washed in by water. No evidence was found by the writer in Cornwall, or in Malaya, of soln. of cassiterite by ground water. ALICE W. EPPERSON

Origin of the strontium in the strata of the lower Muschelkalk and Röt formations near Jena. K. DINGER. *Chem. Erde* **4**, 167–77(1929).—The celestite occurring in certain strata of the lower Muschelkalk and Röt formations is not primary, but is due to secondary enrichment. The Sr has been transported in soln., probably as $Sr(HCO_3)_2$, and pptd. as sulfate by interaction with gypsum, since the deposits of celestite occur only where this mineral is, or has been, present. Spectroscopic and chem. examn. of the various strata of the above 2 formations showed the presence of traces of Sr in practically all cases, derived initially from sea water through the agency of certain radiolaria which abstract it to form their shells. B. C. A.

Search for phosphate deposits in U. S. S. R. A. D. ARKHANGELSKII. *Compt. rend. acad. sci. U. S. S. R.* **1930A**, 97–101.—Possible sources of phosphates in Russia have not been so far thoroughly investigated. A thorough study is recommended, especially in Crimea, Caucasus and Turkestan, not only of known types of deposits, but also of general distribution of phosphates in sedimentary rocks. Most of the deposits known at present are of low P content and are scattered among other minerals over a large area in thin layers. Formation of phosphates from limestones by means of reaction with NH_4 phosphate originating from deposits of guano is outlined, and possibility of this phenomenon in Russia given consideration ROBERT SCHLESS

Asbestos milling in Rhodesia. F. E. KEEP. *S. African Mining and Eng. J.* **41**, Pt II, 89–90(1930); cf. *C. A.* **24**, 3198.—Serpentinization and the formation of chrysotile asbestos in the Great Dyke of Rhodesia are probably due to surface waters. The zones are localized in zones of weakness. Of the rock passing the grizzly at the mill head, 8–12% passes to the cleaning mill as fiber and grit. ALDEN H. EMERY

Genesis of the emery deposits near Peekskill, New York. JOSEPH L. GILLSON AND JOSEPH E. A. KANIA. *Econ. Geol.* **25**, 506–27(1930).—These deposits, still mined on a small scale, are located 35 mi. N. of N. Y. City on the east bank of the Hudson, along and on both sides of the contact of the Manhattan schist and Cortlandt intrusives. G. and K. present data disproving the assimilation theory of the deposits and proving that they are contact-metamorphic in origin and were formed by gaseous or liquid emanations from the magma reservoir which passed upward through the already solid border of the igneous mass and into the schist. A detailed mineralogical and petrographical description of the rocks and ores is given. ALICE W. EPPERSON

The origin of the talc and soapstone deposits of Virginia. J. D. BURFOOT, JR. *Econ. Geol.* **25**, 805–26(1930).—The geographic distribution of these deposits is discussed, and their characteristics described. The presence or absence of talc, soapstone or steatite in this region is thought to depend, in part at least, on the occurrence of the correct segregation product—pyroxenites, peridotites or dunites; on the presence of feeding channels leading to these rocks; and on the invasion of the correct type of solns., that is, solns. of the correct chem. character with the requisite temp. and pressure. The condition of differential stress is not necessary for the formation of talc. The mineral association and paragenesis seem to indicate that talc is formed under deep or intermediate vein zone conditions. ALICE W. EPPERSON

Origin of the white clays of Tuscaloosa age (Upper Cretaceous) in Alabama, Georgia and South Carolina. GEORGE I. ADAMS. *Econ. Geol.* **25**, 621–6(1930).—A. believes that the white clays in the district were not the result of marine deposition, as held by Newmann. Deposition of clayey material in small shallow fresh-water lakes is more commensurate with the extent of the white clay bodies, but does not explain the massive character of the beds. It is suggested that the massive character and purity of the clay are the result of the local alteration of deposits of impure clays. No attempt is made to explain the chem. processes which are involved. A satisfac-

tory explanation must be applicable to all the white clays in the region which are similar in character, whether their sources were the crystallines and metamorphics, or the sedimentary areas, and whether they occur in the Tuscaloosa or other formations.
ALICE W. EPPERSON

Clays of the Jackson Purchase region, Kentucky. JOSEPH K. ROBERTS. *Econ. Geol.* 25, 832–6(1930).—The geological formations of this region range from the limestone and chert of Mississippian to the Recent surficial deposits. Detailed descriptions are given of a number of the clays. Tables of chem. analyses are included.
ALICE W. EPPERSON

Geology of Tshasoff-Jar fireclay deposits. P. A. ZEMYATCHENSKII. *Trans. Ceramic Research Inst.* (Moscow) **1929**, No. 20, 7–29(in German 182–3).—The fireclay occurs in beds in Tertiary Pollawa sands. Intact, horizontal layers are found, frequently curved or folded, sometimes compressed or even torn off the main mass. Perpendicular sections are not uniform in sand content, color and $Fe(OH)_3$ inclusions. There is also included lowigite and alunite, usually in white and yellow nodules from the size of a pea to 20–30 cm. The clay bed is 4.5–6 m. thick, sandy at the top. The area worked is about 1200 hectares, by several concerns and at 24 places. Without careful sorting, the quality of the clay suffers from the presence of lowigite, which on burning gives SO_2 and SO_3, causing swelling and blistering. Na_2SO_4 remaining from the lowigite is a good flux, and if coned. at certain points can cause holes to form in the ceramic object. It is proposed to levigate the clay to make it uniform and to purify it. Based on surveys, about 15 million tons of clay are available.
F. M. SYMMES

Composition of clay from the Tshasoff-Jar deposits. V. ISKYUL. *Trans. Ceramic Research Inst.* (Moscow) **1929**, No. 20, 30–87 (in German 184–7). cf. preceding abstr. Examn. by microscope and detn. of *n*s showed the clay to be mainly kaolinite in the form of shredded flakes, muscovite in colorless scales and slightly rounded quartz grains. Tourmaline and limonite were present, the former in free, prismatic particles or em bedded in quartz grains, the latter as compact clusters or granules distributed through out the clay. Rutile grains were found in only the finest clay fractions, zircon in long grains or whole crystals usually in the coarse fraction. Strongly weathered feldspar, lowigite and alunite were found in rounded grains, and biotite in brown plates. The clay was sepd. by the Sabanin and Robinson method into fractions > 0.05 mm., 0.05–0.01 mm. and < 0.01 mm. Chem. analyses showed high alkali content. About 1.2% TiO_2 was always found, but not much Fe_2O_3, CaO and MgO. SO_3 was present, derived from lowigite and alunite. The org. content corresponded to humus. The crude clay reacts very little with Na_2CO_3 soln. or with 2 and 10% HCl, but ignited clay reacts easily, Fe_2O_3, CaO, MgO and alkali being extd. The clay is a kaolinite mica quartz rock.
E. M. SYMMES

Mineralogical composition of Doubrovka kaolin and its fractions by rational analysis. T. KRASENSKAYA. *Trans. Ceramic Research Inst.* (Moscow) **1929**, No. 21, 3–25 (in German 26–7). The change of mineral compn. of kaolin on alteration from coarse to fine fractions was detd. and mineral impurities were identified. The kaolin was decompd. by 10% HCl after dehydration at 600°, followed by a 2-hr. extn. by 5% Na_2CO_3 soln. Microscopic examn. of kaolin showed the presence of kaolinite, quartz, mica and feldspar. Ease of decompn. of mica and feldspar is not given in the literature. Their proportions were estd. by microscopic count. Mica was 95% decompd. by the HCl and Na_2CO_3, and feldspar about 23%. Tables show the mineralogical compn. of unground kaolin and its coarser fractions. In the finer fractions kaolinite rises, but mica, feldspar and quartz diminish.
E. M. SYMMES

Bohemian clay. G. LINCK AND E. KÖHLER. *Chem. Ztrde* **4**, 459–60(1930).—A clay from the Tertiary lignite beds was analyzed in bulk and also the portion sol. in HCl after ignition at 600°; the dehydration curve is plotted. It contains kaolin 47.58 with amorphous material 18.94%, quartz 40% and some mica, pyrite and org. matter.
B. C. A.

A new locality of gaylussite in eastern Mongolia with associated natural soda. K. NIINOMY. *Econ. Geol.* **25**, 758–63(1930). The topography of the region is described, and the occurrence of Na minerals and of gaylussite is given, with typical analyses. The origin of these minerals is discussed, but no definite theory is formulated.
ALICE W. EPPERSON

Geological aspects of the formation of coal. CYRIL S. FOX. *Proc. 16th Indian Science Congress, Geology Sect.*, October 25, **1929**; *Fuel in Science & Practice* **9**, 548–59(1930).—Stratigraphical and petrological data obtained from field investigations and lab. studies of Indian coals are presented in a detailed discussion of their occurrence, quality, origin, constitution and formation. From these data and the results of nu

merous other researches—39 references are included—F. draws 16 conclusions concerning the formation of coal. The main processes in the conversion of peat into primary coal are considered to be of a chem. character and involve all the plant components. Coalification proceeded under water, under anaerobic conditions, sometimes before deposition of overlying sediments. Primary coal became heated because of pressure and was thus changed into bituminous or anthracite coal depending upon the degree of carbonization. In some cases where carbonization proceeded far enough locally, as a result of catalytic action in capillary spaces, fusain was formed. D. A. R.

Coal as a recorder of incipient rock metamorphism. MARIUS R. CAMPBELL. *Econ. Geol.* **25,** 675-96(1930).—Evidence is given to indicate that 8 stages in the metamorphism of coal can be recognized and explained by the processes that have been active in the earth coincident with the development of plant life on the land, and that at least 6 of these stages have left few if any marks on the compn. or phys. appearance of the sediments assocd. with the coal. They may, therefore, be classed as incipient stages of rock metamorphism. ALICE W. EPPERSON

Studies in the development of Dakota lignite. V. Extraction and study of the benzene-soluble portion of Dakota lignite. E. E. HARRIS, C. F. BELCHER AND A. W. GAUGER. *Ind. Eng. Chem.* **23,** 199-204(1931) Lignite from the Velva deposit in N. D. was extd. by the Fisher (*C. A.* **11,** 1739) and Bone (*C. A* **23,** 951) methods and a study made of the C_6H_6 sol. portion. Up to 4.3% of the dry, ashless coal substance was extd by the Bone method That portion of the ext obtained up to 17 atm. has a compn. closely analogous to *Montan wax* from German brown coal. A. H E.

Some chemical aspects of the origin of petroleum. S. C. LIND. *Science* **73,** 19-22(1931) - The chem complexity of petroleum is little less miraculous than its abundance This discussion is directed toward the origin of the complexity rather than the initial source of natural hydrocarbons Processes, either thermal or ionic, are now known by which progression both up and down the hydrocarbon series is effected. This leads directly to the complexity found in natural petroleums, and also found in synthesized ones. Consequently, the starting material, whether of vegetable, animal or mineral source, does not need to be a complex mixt., but may be a single chem. species, from which a high degree of complexity is obtained by steps which appear simple when chem and thermodynamic properties of hydrocarbons are considered. The simplicity of such a mechanism may lend indirect support to the old idea of inorg. origin from one or a few hydrocarbon gases such as might be produced by action of water on metallic carbides in the earth's interior. On the other hand, it does not preclude animal or vegetable origin, but strongly suggests that the primary material, whether gaseous, liquid or solid, is later subjected to thermal (or ionic) agents or both, which produce the complexity found in nature ALICE W. EPPERSON

Study of the black shale overlying the cap rock of the Cromwell sand in relation to the origin of the Cromwell oil dome, Oklahoma. OLIVER R. GRAWE. *Econ. Geol.* **25,** 326-47(1930). An investigation of 54 samples of this shale has shown that its lithologic properties and its compn. are as const as can be expected of any rock No variations occur which can be correlated with local metamorphism produced by structure-forming forces Slight differences in color are independent of the structure and seem to accompany changes in compn. (especially in carbonate content) which may be best explained on the basis of sedimentation. Although shales from different stratigraphic horizons show increase in sp. gr. with depth, sp. gr. of the shale from a single horizon is constant, regardless of structure. Gardner's suggestion that a careful study of properties and compn. of the shale in the low domelike structures of the Mid-Continent field may prove the presence of slight localized metamorphism has not been substantiated, and it is unlikely that local forces of the type postulated by Gardner could have produced the Cromwell dome. ALICE W. EPPERSON

Limestone oil reservoirs of the northeastern United States, and of Ontario, Canada. A. N. MURRAY. *Econ. Geol.* **25,** 452-69(1930) On theoretical grounds the most effective, if not the only, way in which sufficient porosity can be developed in limestone to provide a reservoir of commercial importance, is as a result of soln. above a water table. The porous limestone reservoirs in the northeastern U. S. and Ont. all have been shown to have been subjected to erosion before the time of deposition of the formation now overlying them, with the possible exception of the limestones of Traverse age in Mich. It is therefore suggested that erosion caused the development of porosity in the case of all these limestone reservoirs. ALICE W. EPPERSON

Some properties of limestone as a reservoir rock. W. V. HOWARD AND W. W. LOVE. *Econ. Geol.* **25,** 720-36(1930).—The expts. described indicate that oil will migrate through limestone, but that most of the oil is absorbed by the rock, particularly

the lighter fractions of oil. In a thick reservoir heavy residues may collect in tighter zones within the reservoir with the result that porous limestone is divided into "pays" separated by an asphaltic limestone, as well as by other impervious beds. Such division into zones makes difficult the application of exptl. results to field conditions. It appears that normal production methods will remove from the area tributary to any well all oil which that well can be expected to produce, regardless of rate of production. The low sp. gr. typical of oils from limestone reservoirs appears to be the result of absorption of lighter fractions by the rock ALICE W. EPPERSON

Chemical and petrological investigation of bituminous rocks of various ages from northern Germany. F. HIEBENTHAL. *Chem. Erde* **4**, 343–68(1929).—Bituminous material from 4 different formations (Alluvial, Diluvial, Tertiary and Cretaceous) has been examd. chemically and petrologically. The bitumens from these marine sediments show increasing C content with age, but unlike those of terrestrial origin there is no corresponding decrease in the H content. Elementary S was found in the specimen from the Alluvium, and a stable "metabitumen" was detected in the Tertiary rock. B. C. A.

A tholeritic phase of the quartz-dolerite magma of central Scotland. FREDERICK WALKER. *Mineralog. Mag.* **22**, 368–76(1930).—The rocks near Dalmeny and Kinkell are described, with chem. analyses, and shown to contain chlorophaeite. The analyses and *ns.* indicate that the residual glass is of acid compn. in both cases. A. M. BRANT

Granitic rocks of Tsukuba district and their associated injection-rocks. KEN-ICHI SUGI. *Japan J. Geol.* **8**, Nos. 1/2, 29–112(1930).—Around the granite rocks of the district hornfelses and injection-rocks are extensively developed. Biotite-granites (granodioritic) constitute the main body of the igneous rocks, being assocd. with aplitic granites, aplites and pegmatites which occur as small sheets and are especially abundant near the contact borders of the granites. These granitic rocks may have intruded during the Mesozoic era. The metamorphic rocks are believed to have been derived from the sedimentary complex of the Chichibu series, the metamorphism being due to the igneous intrusions. Of the hornfelses which occupy the eastern part of this area, the predominant types are those derived from argillaceous sediments, andalusite- or cordierite-hornfels, which show gradual transitions to the injection-rocks of the western area. The latter, derived largely from argillaceous sediments, are grouped in 4 main types, *viz:* sillimanite-biotite-, biotite- with shimmer aggregates, cordierite-biotite and biotite fels. There are also metamorphic rocks derived from Ca-Mg-bearing sediments, which are almost free from igneous injection but not from its effects. A few chem. analyses are given. W. L. HUH

Geological and petrographical examination of the granites quarried in Silesia. W. BECKER AND F. MACHT *Chem. Erde* **5**, 412–36(1930).—Details are given of the stone from several quarries in the neighborhood of Strehlen, including the jointing of the rock, the size of grain of each constituent mineral and the relative proportions of each mineral These are points of importance in the quarrying of the stone and in its suitability for various purposes B. C. A.

Phonolites and trachytes of the Laacher See district. W. AHRENS. *Chem. Erde* **5**, 1–21(1930).—Trachytoid phonolitic tuffs at Burgbrohl, belonging to the Alluvial period, are of later age than the main mass of trachytes of the Laacher See district The contained blocks of trachytoid phonolite lava are described petrographically with chem. analyses. The analyses are compared with published analyses of the trachytes and plotted on diagrams, showing that at this later period the magma became more acid. B. C. A.

Mineralogy and petrography of the Rhön Mountains. F. HEIDE. *Chem. Erde* **5**, 396–411(1930).—Petrographical descriptions are given of phonolite rocks, with one chem. analysis. B. C. A.

Basalt from the Atlantic Ocean. C. W. CORRENS. *Chem. Erde* **5**, 76–86(1930). A description with chem analysis is given of a fragment (62.7 g.) of basalt raised from the floor of the Atlantic at a depth of 2000 m. in lat. 1°56′ S., long. 12°40.7′ W. It has a glassy crust which has been acted on by sea water. B. C. A.

Basalt of the Stöffel, Westerwald [Nassau]. E. LEHMANN. *Chem. Erde* **5**, 319–72 (1930).—From this hill of Miocene basalt 600,000 tons of stone are quarried annually The basalt is penetrated by dikes of essexite-porphyry, which is a product of differentiation of the basaltic magma. Detailed petrographical descriptions with chem. analyses are given of these rocks. B. C. A.

Dolomitization of Middle Devonian [limestone] in the Eifel. P. MÜLLERS. *Chem. Erde* **4**, 431–54(1930).—Many analyses are given of the dolomite rock in the Gerolstein

basin. They show in the majority of cases 80–96% of dolomite ($CaCO_3.MgCO_3$), but in a few streaks only 1–2%. The rock is a coral-reef formation; the dolomitization took place contemporaneously by the action of the sea water. The undolomitized streaks represent lagoon deposits. B. C. A.

Rocks of Gomera, Canary Islands. W. Müller. *Chem. Erde* **4**, 369–94(1930).—The Tertiary or post-Tertiary volcanic rocks of the island of Gomera are underlaid by a series of extensively weathered rocks which were believed by Gagel (*C. A.* **20**, 3414) to represent a much older "Grundgebirge." A detailed examn. with several analyses of these rocks shows that they are only the weathered equivs. of the ordinary types of volcanic rocks, which include basalts, trachytes and trachytic phonolites. Analyses are also given of the portion of the weathered rocks sol. in HCl. B. C. A.

Red marls of the Trias formation. H. E. Krauss. *Chem. Erde* **4**, 188–207 (1929).—A no. of marls from the red Trias formation have been subjected to chem. and rational analysis, and their mineral compn. has been calcd. After subtraction of clastic minerals (quartz, feldspar and carbonates) and recalcn. of the results to 100% it is found that the ratio of $Al_2O_3:SiO_2:H_2O$ in the residual material is practically the same as that in specimens of "terra rossa." It is therefore concluded that both these substances represent similar products of weathering. B. C. A.

"Terra rossa" as residue from solution of marine limestones. Wilh. Graf zu Leiningen. *Chem. Erde* **4**, 178–87(1929).—A series of comparative analyses of "terra rossa" from a no. of localities and of material left after the soln. of various limestones is adduced as addnl. evidence in support of L.'s view that the first-named substance is to be regarded as a soln.-residue of certain marine limestones. B. C. A.

"Terra rossa" as solution residue of marine limestones. E. Blanck. *Chem. Erde* **5**, 43–7(1930). The analyses by Leiningen (preceding abstr.) support the view first expressed by B. in 1915 B. C. A.

Natural weathering and a comparison of chemical and natural weathering of building stones. E. Kaiser. *Chem. Erde* **4**, 290–342(1929).—In a study of the effects of natural weathering in a region, the properties of the underlying strata are important, since the nature of these often greatly influences the effects due to climatic weathering, certain oases furnish instances of this kind. The weathering of building stones caused by various gases present in the atm. is fully discussed, and the analogy with natural weathering is traced. Analysis of a block of sandstone taken from Regensburg Cathedral showed that of the salts formed by weathering, $CaSO_4$ tended to be concd. in the outermost layers, while $MgSO_4$ and Mg chlorides had penetrated deeply into the stone. The presence of alumina and silica in the sol. salts due to weathering was also noted, but it is uncertain in what form they occur. Chem. weathering is intensified by light, and building stones exposed to full light are more rapidly corroded than those in a more shaded position. B. C. A.

Bleaching processes [in rocks]. H. Harrassowitz. *Chem. Erde* **5**, 146–64 (1930). Many different geological processes may give rise to much the same result. Exogene bleaching and endogene bleaching are distinguished; the former is due to ordinary weathering at the surface, and the latter to fumarole and hydrothermal actions. By the removal of certain constituents the rocks may be altered to kaolin, bauxite, alunite, etc., or even to a pure quartz sand B. C. A.

Weathering of shell limestone and soil formation near Jena. W. Hoppe. *Chem. Erde* **5**, 165–81(1930).—Several chem. analyses are given of limestones from different strata in the "Muschelkalk," of the weathered rocks and of the overlying soils. These show a gradual removal of lime and an accumulation of the residual constituents of the limestone. B. C. A.

The abundance of elements of the vanadium group in eruptive rocks. G. v. Hevesy, E. Alexander and K. Würstlin. *Z. anorg. allgem. Chem.* **194**, 316–22 (1930). Two hundred and eighty-two samples of eruptive rocks were examined for V, Cb, Ta and protoactinium content. The mean Cb and Ta content was 3.2×10^{-7} or 2.4×10^{-7} g per gram of rock. The relation of at. abundance of Cb and Ta is 2.6. The V content was 2×10^{-4} and the protoactinium content (calcd. from the Ra content of 1.2×10^{-12}) 7×10^{-13} per gram. A comparison was made of the abundance of these elements of the V-group in the eruptive rocks and in meteorites. M. M.

The significance of silicate synthesis for geochemistry. Wilhelm Eitel. *Naturwissenschaften* **18**, 1019–20(1930).—A review of recent work in silicate chem.
B. J. C. van der Hoeven

The age of the earth. Otto Hahn. *Naturwissenschaften* **18**, 1013–9(1930).—A review.

9 METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, H. W. GILLETT AND RICHARD RIMBACH

Metallurgy and the power industry. J. B. ROMER. *Metals and Alloys* **1**, 868-70 (1930).—A review. A. J. MONACK

Metallurgy in South Africa. S. W. SMITH. *Mining Mag.* **43**, 265-9, 336-41 (1930); **44**, 24-31(1931). A survey of operations at various works, especially those for Au, Pb, Cu and Fe, with discussion of papers presented at the Empire Congress. A. BUTTS

Lead. G. W. THOMPSON. *Am. Metal Market* **38**, No. 35, 3, 5, 10 (Feb. 20, 1931).—The great increase in consumption of Pb has been in the elec. industry, where it is chiefly used for cable coverings. The problem in the future of the Pb and Cu industries will depend largely upon the demand created by the elec. industry. Properties of Pb and its alloys with Sb or Sn or both are discussed. W. H. BOYNTON

The Roan Antelope copper mine. A. G. MCGREGOR. *Mining Mag.* **43**, 270-6 (1930). A description of the mine, mill and smelter, with several flow sheets and diagrams. Initial production will be 50,000 tons of Cu yearly. A. BUTTS

Milling practice at Fresnillo. R. E. BYLER. *Mining Mag.* **42**, 137-47(1930). A description of practice in cyaniding an oxidized Ag ore and differential flotation of Pb-Ag-Zn sulfide ore. The cyanide is regenerated by treating the soln. with SO_2 and absorbing the liberated HCN in alk. soln. A. BUTTS

Amulet flotation mill practice. W. G. HUBLER. *Can. Mining Met. Bull.* No. **226**, 295-306(1931). Operations at the new 300 ton mill treating Cu-Zn-Fe ore by selective flotation are described, and the use of various reagents is discussed. A. BUTTS

The new smelter and concentrator of the International Nickel Company at Copper Cliff, Ontario. L. M. SHERIDAN. *Eng. J.* (Can.) **13**, 682-7(1930). After coarse crushing by hand at the mines, the ore is shipped to Copper Cliff where it is crushed to 200-mesh and sent through a wet concn. to remove the rock. In the concn. process the sulfides are floated, and the lighter rock material sinks to the bottom. By selective flotation a rough sepn. is made of the Cu and Ni. Smelting comprises roasting in multiple-hearth roasters, in reverberatory furnaces and blowing in basic-lined Bessemer converters. The product is an 80% Cu-Ni mat. The layout of the smelter and concentrator is shown in a diagram. W. H. BOYNTON

The Hollinger assay office. W. R. DODGE. *Can. Mining Met. Bull.* No. **225**, 115-22(1931). The equipment and work of the lab. of the Hollinger Consolidated Gold Mines are described. A. BUTTS

Review of iron and steel literature for 1930. E. H. MCCLELLAND. *Blast Furnace Steel Plant* **19**, 258-61(1931). E. H.

Recent developments and researches in cast iron. J. W. DONALDSON. *Roy. Tech. Coll. Met. Club J.* (Glasgow) **1929-30**, No. 7, 38-40. E. H.

Evaluation and testing of the properties of raw materials and key-products in the iron industry. A. WAGNER. *Stahl u. Eisen* **50**, 655-68(1930).—The present state of our knowledge of the properties of coal, coke and Fe ore used in the production of Fe and steel and of the pig Fe produced from various types of ore is reviewed, and modern methods of detg. the value of these materials for their particular purposes are briefly discussed. Lab. tests of the coking power of coal and chem. analyses of Fe ore do not give sufficient information as to the value of the coke and ore for metallurgical purposes, as no account is taken of their phys. condition, which is of considerable importance in detg. their behavior in smelting. Similarly, chem. analysis of pig Fe affords little information as to its value for subsequent operations, but, in combination with an examn. of its micro- and macro-structure and a detn. of its mech. properties after remelting under standard conditions, the analysis gives a fairly accurate idea of the com. value of the metal. B. C. A

Calorific value, heat and gas flow, the physical bases of metallurgical processes. H. BANSEN. *Stahl u. Eisen* **50**, 668-78(1930).—Diagrams have been constructed to show the heat balance in various stages of Fe smelting—the blast furnace, gas producer, acid and basic open-hearth furnaces, converter and sponge Fe producer—and the effect of preheating the gas and air is illustrated. A knowledge of the calorific value of the fuel and the rate of flow and heat content of the various gases is shown to be of paramount importance in the correct and efficient operation of the various processes. The resistance of the column of charge in the blast furnace to the flow of gas through the furnace dets. to a large extent the output of the furnace, and any factor which increases this resistance reduces the efficiency of the furnace. One of these factors is the deposition of C from the flue gases in the upper part of the blast-furnace shaft; an app. is described and illustrated for the detn. of the magnitude of this deposition from blast-furnace gas. B. C. A.

The carbon-oxygen equilibrium in liquid iron. H. C. VACHER AND E. H. HAMILTON. *Am. Inst. Mining Met. Eng., Tech. Pub.* No. **409**, 13 pp.(1931).—The product of the C and O concns. in liquid Fe at 1620° was found to be 0.0025 at 1 atm. pressure. The same const. was obtained over a range of 0.01–0.94% C and 0.003–0.19% O. Expressed as the product of FeO and C it becomes 0.011. H. C. PARISH

Improving castings with the double forehearth. CARL REIN. *Giesserei-Ztg.* **27**, 8–11(1930).—Cast Fe melted in a cupola can be improved by a complete deslagging. This is accomplished by allowing the melt to stand a while, so that the slag particles may rise to the top. Where various mixts. are melted in the same furnace, the double forehearth has the advantage of keeping the individual melts sep. It is heated to a white heat with an oil burner before tapping, so as to not cool the charge. C. L. W.

Development of the modern blast furnace. GEO. F. ROSE. *Blast Furnace & Steel Plant* **19**, 255–7(1931). E. H.

The cupola furnace and its main dimensions. LEOPOLD SCHMID. *Giesserei-Ztg.* **26**, 567–77(1929).—A discussion of the construction and operation of the Fe-foundry cupola, with and without forehearth. CURTIS L. WILSON

The combustibility of coke in cupola practice. J. GWOSDZ. *Giesserei-Ztg.* **26**, 578–82(1929).—A dense, hard, difficultly combustible coke is the most suitable for cupolas, as it does not reduce CO_2 back to CO so readily. CURTIS L. WILSON

The selection of coke for foundry purposes. OTTO HUPPERT. *Giesserei-Ztg.* **27**, 35–7(1930).—Low H_2O, ash, and S content and high strength are desirable. For cupola coke, low activity (velocity of reducing CO_2 to CO) is debatable. This activity is attributed to the unsatd. amorphous C atoms. When activity is desired, the graphitization caused by coking at too high a temp. is to be avoided. Cf. *C. A.* **24**, 224. CURTIS L. WILSON

Wrought iron, some pros and cons, and the need for research. H. W. GILLETT. *Metals & Alloys* **2**, 25–30(1931). A correlated abstract. A. J. MONACK

Producing hydraulic cylinder castings. F. LONGDEN. *Iron and Steel Ind. and Brit. Foundryman* **4**, 115–8(1931). C. H. LORIG

Character of change of hardness of iron ruptured by tension. M. MIKHAILOV AND I. CHURBANOV. *Acta Univ. Asiae Mediae*, Series XI, Tech., No. **3**, 1–5(1929).—Hardness tests (Shore scleroscope and Rockwell) made on samples of iron broken by tension showed that the hardness of the surface and of deeper layers increased in all parts of the specimen except the necked portion. On the portions corresponding to the neck the hardness of the surface layers decreased 21%, but the hardness of the inner layers increased 20%. B. N. DANILOFF

The strength of gray cast iron at elevated temperatures. J. W. DONALDSON. *J. West Scot. Iron Steel Inst.* **38**, Pt. II, 11–20(1930). Cast irons comprising 2 plain irons contg. 0.65 and 1.48% Si, resp., and alloy irons contg. (*a*) 2.43% Mn, 0.40% Cr, 0.75% Ni, 0.12% V, 0.48% W and (*b*) 0.61% Cr, 0.30% Ni, 0.02% V, resp., were investigated to det. (1) the temp.-stress curves of a series of plain and alloy irons, (2) the influence of previous heat treatment on the temp.-stress curves, and (3) the effect of low Si and various alloy addns. on the strength of cast Fe at elevated temps. both as cast and after heat treatment. DOWNS SCHAAF

Plastic and elastic deformation. E. KIEFT. *Iron Steel Eng.* **8**, 54–66(1931).—The compression-resistance of wrought iron and mild steel increases to unknown values when we compress plastic material. The rate is very great when the height is very small as compared with the diam., because of the rapid increase of expansion or horizontal resistance. An observed increase in resistance per sq. in. was from 50,000 to 230,000 lb. The applied force works vertically and is transmitted by deformation or displacement of the molecules into horizontal direction. Expansion work must be considered along

with compression work when deriving a formula in which tensile strength or compression strength of steel is taken as a const. during the whole operation. The soln. of problems relating to plastic and elastic deformation involves application of the law of least resistance or least work. Twenty-two equations are evolved relative to the plastic flow of hot steel, of cold steel and of elastic flow. The strength can be improved, and a considerable amount of material can be saved by proper design of frames, rollstands or similar structures. Application of the theory of least work, credited to Castigliano, yields the same result as indicated in the formulas. W. H. BOYNTON

Wearing tests on iron and steel. ARVID JOHANSSON. *Jernkontorets Ann.* **114**, 551–71(1930).—A critical discussion is given of various tests for wearing resistance, including the Robin, Brinell, Spendel and Amsler tests. The general conclusions are that wearing resistance increases with increased C content, with increased coarseness of structure and with increased speed of rotation. The general status of the results is, however, highly uncertain. Problems for further research are the effect of crystal structure as detd. by chemical analysis, heat treatment, final working temp., and slag inclusions. Seven references are included. H. C. DUUS

Investigation of a raw steel from pre-Roman times. H. HANEMANN. *Stahl u. Eisen* **51**, 67–8(1931).—A steel bar from the pre-Roman La Tène period was subjected to chem. and metallographical analysis. The irregular structure showed dark parts consisting of pearlite and cementite and lighter parts consisting of ferrite and pearlite. The chem. analysis showed 0.44% C, 0.065% Si, 0.10% Mn, 0.042% P, 0.012% S, traces of Cu and no other metals. The steel of that period could only have been made in the bloomery hearth. Forging expts. showed that sharp knives could be made from this steel but not without some difficulty due to the formation of cracks. This steel bar, over 2000 years old, is a good example of the great stability of cementite. J. A. SZILARD

Testing method for the determination of the surface characteristics of [steel] plates. E. GEROLD. *Stahl u. Eisen* **51**, 104–6(1931).—The luster of the surface of iron plates is a measure of their smoothness. Several methods to measure the luster of plates are described. The polarization luster measuring apparatus built by Schmidt and Haensch (cf. K. Kieser, *Z. angew. Chem.* **32**, 357 (1919)) utilizes a polarization photometer to measure the amt. of polarized light in rays reflected from the surface to be tested. The stray luster measuring device, built according to Kempf-Flugge by the same firm, photographs the image of a small slit by means of the rays reflected from the surface to be tested. The clearer the image of the slit, the better the reflecting power and the smoother the surface of the plate. The Askania luster-measuring app. is built on the same principle except that, instead of exposing a sensitive paper, the observer reads the luster of the surface under test directly by comparing the divergency of the rays from the same point of the surface. The app. designed by the research lab. of the Vereinigte Stahlwerke Dortmund is similar to the above, except that a photoelectric cell is used to measure the amt. of light reflected from the surface. Because of the comparatively small surface area possible to cover with the above app., this method is not suitable as an acceptance test for plates. However, it gives valuable information on the surface characteristics of plates when the adhesion of paints and varnishes is being studied. J. A. SZILARD

Influence of high-frequency oscillations on the treatment of metallurgical products G. MAHOUX. *Compt. rend.* **191**, 1328–30(1930).—All expts. were made on rods 15 mm. in diam. Steel contg. 3% Ni, 3% Cr and 1% Mo was heated 9 hrs. at 500° in a current of NH_3, with a blank not electrically treated. The Brinell-Vickers no. was raised from 380 to 1030, the resilience from 9 to 11.8 kg., and the nitride penetration was 0.35 mm. The only change in the blank was a nitride penetration of 0.01 mm. The B.-V. no. of steel contg. 8% Ni, 19.8% Cr and 4% W, treated 10 hrs. at 500° in NH_3 was raised from 235 to 1035 at the surface, to 570 1 mm. beneath the surface, and to 472 at the center. A soft steel electroplated with Cr and treated 9 hrs. at 530° showed a Cr penetration of 0.35 mm.; the blank showed no penetration. **Comments on the preceding communication.** LEON GUILLET. *Ibid* 1331–2.—The results have been confirmed by Aubert and Duval for steel and many alloys. A Ni coating on steel is absorbed at 450°. The treatment opens a fertile field for research. J. H. M.

The formation of cracks in steel castings. K. SINGER AND H. BENNEK. *Stahl u. Eisen* **51**, 61–5(1931).—The possibilities of the formation of so-called hot cracks during the cooling of steel castings and the filling up of these cracks or fissures by the liquid part of the casting are reviewed with reference to practical examples. The cracks are caused by great temp. differences in the casting, by the manner of heat transfer from one part of the casting to the other and mainly by the size and shape of the coldest

part of the casting, from which during solidification contraction forces are acting on the rest of the casting. There is no direct relationship between piping and cracks, although by working toward a pipe-free casting, the better temp. conditions prevent the formation of cracks and help in filling up those formed by the liquid part of the casting during the cooling period. The importance of the proper contraction of the casting is emphasized. Were it possible to control the shrinking of the casting, the danger of the formation of cracks would be greatly reduced. It is pointed out that in a casting solidifying in a field of a high frequency coil the induction current would counterbalance the radiation losses, thereby preventing the formation of cracks. J. A. SZILARD

Aging of steel castings. A. POMP. *Stahl u. Eisen* **50**, 440–1(1930).—The impact strength of mild-steel castings (notched bars) contg. C 0.1–0.27, Si 0.16–0.46, Mn 0.45–1.37, P 0.05–0.06 and S 0.04% decreases on aging at 250° for 1 hr. after forging to a reduction in area of 7–10%, but not nearly to the same extent as it does after completely annealing. The values obtained for the annealed metal at 20° to —20° were consistently below 2 m. kg./sq. cm., whereas those for the aged metal varied from about 6 m. kg./sq. cm at 20° to about 2·3 m. kg./sq. cm. at —20°. B. C. A.

Effect of various annealing temperatures on cold-worked low-carbon steel. H. E. PUBLOW *Metals & Alloys* **2**, 18–9(1931).—The results are expressed by 3 graphs which show (1) the *relation between annealing temps. and Rockwell hardness* of 4 low-C steel brake drums, (2) the *relation between annealing temps. and ductility* and (3) the relation between annealing temps. and hardness and ductility of cold-worked low-C steel. A. J. MONACK

Cold-rolled steel. GEORGES DELBART. *Aciers spéciaux* **5**, 483–508(1930).—This work covered (1) influence of *cold rolling and successive annealings on the tensile strength and elongation*, (2) *hardness*, (3) *corrosion by* H_2SO_4, (4) *attack by fuming* H_2SO_4, (5) *influence of cold rolling and successive annealings on the impact strength and* (6) *influence of cold rolling and rapid annealings on the magnetic permeability*. Data and graphs are given in connection with each of the items above. A large number of *photomicrographs* is included. A. J MONACK

Steels for cold pressing. G. R. BOLSOVER. *Iron and Steel Ind. and Brit. Foundryman* **4**, 101–2(1930).—Low-C rimming steels used for deep drawing do not work-harden readily. The tensile strength varies approx. as one-third the % reduction in steel thickness. When steel is stretched more than 5%, brittleness is encountered on reheating to 200° to 300°. Age hardening after quenching increases the tensile strength of dead mild steel 67%. For deep drawing purposes stainless steel must be low in C and should be quenched from a high temp C. H. LORIG

Tensile strength at high temperatures of steel containing small quantities of nickel and molybdenum. W. LIEBSTMANN AND C. SALZMANN. *Stahl u. Eisen* **50**, 442–6 (1930). The tensile properties of steel with C 0.2, Mn 0.8, Si 0.25, Ni 0.4–2.2 and Mo 0.2–0.6% have been detd. at 500° after annealing at 900–950°. Ni and Mo both increase the tensile strength and yield point but reduce the ductility, 0.1% Mo increasing the ultimate strength by 1 kg./sq. mm. and the yield point by 2 kg./sq. mm., and 0.5% Ni increasing the former by 2 kg./sq. mm and the latter by 1.8 kg./sq. mm. With higher proportions of Mo the ratio ultimate strength/yield point is unfavorably affected, but further addn. of Ni improves this ratio. The steel with 2.1% Ni and 0.5% Mo has a yield point of 25.5 kg./sq. mm., a tensile strength of 42 kg./sq. mm., an elongation of 11% and a reduction in area of 20% at 500°. B. C. A.

Solution of cementite in carbon steel and the influence of heterogeneity. ERIK WALLDOW. *Engineering* **131**, 27–30(1931). —Transformation of α-iron to γ iron starts from the grain boundaries. Com. steels show a transformation interval, the transformation starting at different temps. in different parts of the specimen. A new material, "sorbo-troostite," is found when heating at 3·5–5.2° above Ac_1 for 1 hr. or less. Its structure is less distinct than that of sorbite and it is not so strongly attacked by HNO_3 as troostite. It appears to be residual undissolved ferrite and cementite and never to have been in the γ-state. It is found in the peripheral parts of austenite grains. Varying soly. of pearlite grains is not due to alloying elements as contaminators but to their irregular occurrence in the structure. ANN NICHOLSON HIRD

The development of nitriding plants. F. BRÜHL. *Krupp. Monatsh* **11**, 287–90 (1930).—A description is given of the development of nitrided steel together with a discussion of the requirements demanded of nitriding equipment. A number of installations are described. H. STOERTZ

The case-hardening of commercial steels by means of nitrogen. B. JONES. *Iron and Steel Ind. and Brit. Foundryman* **4**, 77–86, 99(1930).—Five British com. austenitic steels of various compns. were nitrided at 500° for 90 hrs. Except for a 13.20% Mn

steel with 1.25% C, the increase in hardness was inappreciable. The austenite in the Mn steel was partially decompd. into troosto-martensite. Nickeliferous austenite does not harden on treatment. The effects of certain elements were ascertained by nitriding 20 com. steels of different chem. compns. for 90 hrs. at 500°. Contrary to published information, plain C steels are nitrided. Mild steels harden to a greater extent than do high-C steels. Nickel steels do not nitride. With Cr and V the retarding effect of Ni is not so great. The effects of the combination Al, Cr, Mo appear to be more than additive. C. H. LORIG

Use of zirconium alloys in steel manufacture. PH. GUY. *Aciers spéciaux* **5**, 509-21(1930).—The following are discussed: (1) action of Zr on the impurities contained in steel, (2) phys. properties of Zr steels and (3) steels for which the use of Zr is recommended. Data and photomicrographs are given. A. J. MONACK

New manganese-silicon alloys for the deoxidation of steel. C. H. HERTY, JR., AND G. R. FITTERER. Bur. Mines, *Rept. of Investigations* **3081**, 14 pp.(1931).—By using Mn-Si alloys for deoxidation, larger inclusions were formed than by using Si alone. The av. size of the inclusions formed when using Si was 15×10^{-4} cm. The size increased with increasing Mn, until at a Mn/Si ratio of 4-18 the largest particles in dead-killed steels were 1000 cm $\times 10^{-4}$. These large particles would rise at a much more rapid rate (600-2400 in. per min.) than the small SiO_2 particles (0.15-1.5 in. per min.). Tests in commercial acid and basic open hearths show the same results on steels of from 0.12 to 0.60% C using alloys with a Mn/Si ratio of 4-5-6-0. Mn efficiencies of 75-85% have been obtained when forging-grade steels have been deoxidized with these alloys. ALDEN H. EMERY

Some important advances in the properties and treatment of metallic alloys. LEON GUILLET. *Rev. métal.* **27**, 449-66(1930); *Rev. univ. mines* **4**, 221-30, 296-306. General review. H. C. DUUS

Examination of the resistance of metal alloys against attack by salt solutions. III. E. MAASS AND W. WIEDERHOLT. *Korrosion u. Metallschutz* **6**, 265-77(1930); cf. *C. A.* **25**, 1205.—Solns. of sylvinite, carnallite, Glauber's salt and bitter salt were used as corrosive media, in which the specimens previously specified were immersed under various conditions. The testing period was 4 months in the expts. carried out at room temp., and 8 days with those carried out at 90°. The losses of wt. and the appearance of the corroded surfaces and of the corrosion products are given in detail. The greatest losses of wt. were observed in the group of the various forms of iron. By addn. of Cr and Ni the material is considerably improved, and Cr-Ni steels give the best results that were observed. The second best group is the Cr-Ni-Fe alloys. Ni and the other Ni alloys show a similar behavior, although they are not quite as good. Between them and plain iron rank Cu and the Cu alloys. No essential difference is observable between Cu, bronze and brass. The losses of wt. of the *β brasses* are slightly lower. The magnitude of the attack, generally speaking, is not so great in solns. as when the sheets are covered with solid salt. The corrosion is mainly restricted to the surface, without penetrating deeper into the metal. The penetration amounts to approx. 0.02 mm. in 4 months. Perforation of the sheets by pits was not observed. A soln. of sylvinite was found to possess the greatest corrosiveness. Generally speaking, the effect of Glauber's salt was much smaller and that of carnallite even less, although exceptions were observed in the series where O_2 was passed through the solns. The influence of the experimental conditions was considerable. The losses of wt. were doubled by using the double quantity of corroding soln. per sq. cm. of area. The same holds true if there is a boundary line of liquid and air. Introduction of O_2 causes losses 5 times as high. The corrosion at 90° was found to be greater after 8 days than that at room temp. after 4 months. LEOPOLD PESSEL

Structure analogies of intermetallic phases. A. WESTGREN AND W. EKMAN. *Arkiv. Kemi. Mineral. Geol.* **10B**, No. 11, 1-6(1930).—In intermediate phases of the β-brass type contg. either Cu, Ag or Au, it has been found that there is a ratio of valency electrons to atoms of 3:2, while in the lattices of the γ brass type the ratio is 21:13. Recently metallic compds. have been found not contg. Cu, Ag or Au with atomic groupings resembling β- or γ-brass, *viz.*, NiAu, MnAl and FeAl, where the atoms of the transition elements behave as if they had a valency of zero. To test the validity of this remarkable rule the authors made a series of alloys corresponding to the general formula A_5B_{21}, where A is a transition element (Co, Ni, Rh, Pd, Pt), and B is either Zn or Cd. The alloys were made in sealed evacuated quartz tubes by heating for about a week at 900-1000°. In all cases where alloying succeeded, a homogeneous material of γ-brass structure resulted, as was evidenced by the powder photograms. The homogeneity range extends for Co-Zn alloys from 15 to 22 at. % Co and for Ni-Zn alloys from

15 to 19 at. % Ni. It was noticed that alloying of transition elements with Al, Zn or Cd gives a much more pronounced decrease in vol. than is the case with alloys formed with atoms having complete inner electron shells. The contraction for Ni_5Cd_{21} amounted to almost 8.7%, although Ni occupies only 19 at. % in the alloy. H. S. v. K.

Packing of atoms in alloys. A. WESTGREN AND A. ALMIN. *Z. physik. Chem.*, Abt. B, **5**, 14–28(1929).—The variation of the linear lattice dimensions with compn. of the alloy has been investigated in the α-phases of the systems Ag–Al, Cu–Al and Ni–Al, and in all cases the parameters are less than those calcd. by Vegard's addn. law from the parameters of the components. From calcns. of the vol. occupied per atom in the various phases of the above systems, and of the systems Cu–Zn, Ag–Zn, Ag–Cd, Cu–Mg and Fe–W, it is shown that, in general, a contraction in at. vol. accompanies the formation of the intermediate phases. The at. vols. in contiguous phases of any system differ only slightly, so that the curves of vols. drawn for a series of phase regions are almost continuous. The vol. contraction is especially marked in Ni-Al alloys, and it is suggested that this depends on the fact that such alloys are formed by the union of an atom which is deficient in a nuclear electron with one of normal type. B. C. A.

The influence of temperature upon the notch toughness of aluminum alloys. TORAO KOBAYASHI. *Mem. Kyojun Coll. Eng.* **3**, 145-53(1930).—Duralumin, Y-alloy and other com. Al alloys were worked, quenched and aged 20 days, after which test pieces were placed in an impact machine and tested at temp. intervals of 50° up to 550°. The heating arrangement was attached to the testing machine and could be removed simultaneously with the release of the pendulum. The notch toughness was found to resemble plasticity, in that it increased with increasing temp., reaching a max. at 450°. CURTIS L. WILSON

Volume change during solidification of manganese and some alloys. KOTARO HONDA, YOSHIHARU MATSUYAMA AND YATSUGU ISOBE. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 906–10(1930); (*Abstracts* 88 (in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, Nos. 275–6). Vol. changes during solidification of Mn and some alloys contg. Mn, Ni or Co are measured by using the thermobalance. Values of V'/V'% (V = vol. of liquid sample at m. p.; V' = contraction by solidification) obtained are: pure Mn (Mn 99.9%, C 0.01%, Al 0.03%, Fe 0.05%, Si trace), −4.50; Mn–C (C 1.10%), −1.60; Ni–C (C 2.23%), +2.06; Co–C (C 2.20%), +2.03. K. KONDA

Macro-etching of tin-base bearing metals. ERNEST B. DRAKE. *Metals & Alloys* **2**, 20–4(1931). A *method* for macro-etching tin-base babbitts of various compns. is suggested. The failures in connecting-rod bearings which have been run in test engines appear most often in the finely crystalline babbitts near the joint. The macro-etched babbitts indicate fairly well the size and distribution of the micro-constituents which may be expected. Centrifugally cast main- and connecting-rod bearings show SnSb cubes, which are generally associated with a smaller no. of CuSn needles than when the SnSb cubes are absent, all imbedded in a groundmass of Sn-rich eutectic when the babbitt is of the type: 85% Sn, 7.5% Sb, 7.5% Cu. The die-cast main- and connecting-rod bearings show no SnSb cubes but do show a larger amt. of CuSn needles imbedded in a groundmass of Sn rich eutectic and delta solid soln. when the babbitt is of the type: 85% Sn, 7.5% Sb, 7.5% Cu. A. J. MONACK

Production of lead-tin alloys from tin slag. EDMUND R. THEWS. *Metallbörse* **21**, 3–4(1931). Sn slags are smelted with Pb or Sn-poor alloys. A purer product is obtained by using type metal. Pb residues can be used with Sn slags to produce an alloy of 8% Sn. For alloys richer in Sn this product is oxidized and used as raw material for the next smelt. Sulfurous ores require a preliminary roasting. The presence of much As is harmful because of the formation of viscous iron arsenides. A coking mixt. contg. 10–25% wood charcoal is best. ANN NICHOLSON HIRD

Zinc and zinc-alloy use in the automotive industry. II. ROBERT M. CURTS. *Am. Metal Market* **38**, No. 22, 5, 10(1931).—This installment deals with Zn wire, extruded Zn shapes, die-castings, the use of fully automatic machines, the introduction of high-grade Zn in die castings, Zn alloys for body hardware, and other equipment. Some data are given on the Zn-Al alloy system. **III.** *Ibid* No. 23, 5.—This instalment deals with heat treatment of Zn base die-casting alloys, water-vapor tests, the disastrous effects of contamination, phys. tests on die casting alloys, and the use of inserts in these alloys. **IV.** *Ibid* No. 24, 5, 10.—Cleaning, etching and Ni plating are discussed. A series of tests indicates that Cd plate may be applied directly to die-casting with no appreciable harmful effects. Attractive coats of enamels, japans and lacquers may be applied to Zn and its alloys. Metallic Zn is used in the automotive industry

for electro-galvanizing as a constituent of brass, as rolled sheet and strip for a variety of fabricated products and in the production of a great no. of die-cast parts. The phys. properties of the various Zn alloys and the ease of application of attractive and durable plated finishes have resulted in annual increases in Zn consumption for automobile parts. Tables show the A. S. T. M. specification B 6-18 for Spelter and the phys. and elec. properties of Zn die-casting alloy contg. 4% Al, 3% Cu, 0.05–1.0% Mg and the balance Zn. W. H. BOYNTON

Fatigue strength of unwelded and welded cast and rolled materials. WALTER B. BARTELS. *Z. Ver. deut. Ing.* **74**, 1423–6; *Giesserei-Ztg.* **27**, 607–16, 637–45, 661–4 (1930).—The type of graphite sepn. is of special significance for fatigue strength. In fine eutectic form a considerable increase in vibratory strength is obtained, even with welded bars. The skin produced on the surface of castings by melting of quartzite is of little significance for increased static or dynamic strength, but the grain structure of the outer zone is important. Annealing in all cases lowers the fatigue resistance of cast Fe. The effect of welds upon low-C steel was studied. The dynamic strength of the weld was greatly influenced by the dynamic strength of the materials welded. The weld in general has a stiffening effect, and hammered welds increase resistance to fatigue. H. STOERTZ

Building up metals with electric arc welding. K. TEWES. *Giesserei-Ztg.* **27**, 585–9(1930).—In arc welding it is customary to add materials to the electrodes which will improve the quality of the weld. Si and Mn have been widely used to bring about deoxidation of the weld, but Ti appears to be more suitable. It combines energetically with O and materially reduces the quantity of oxides in the weld. The TiO_2 which is formed readily floats to the top and can be removed with the slag. Greater homogeneity of the weld results in improved mech. properties. Ti also tends to form nitrides, Ti_3N, TiN, Ti_2N_2 and Ti_3N_4, which greatly increase the hardness of the steel H. STOERTZ

Soft steel welds deposited by the electric arc. D. ROSENTHAL AND M. MATHIEU. *Compt rend.* **191**, 484–6(1930).—The nature of the weld of soft steel bars produced by the elec. arc depends on the manner in which the molten metal is protected from oxidation. Metallographic examn. shows that welds protected with a covered electrode have more regularly formed grains than non-protected welds. X-ray diagrams show the existence of strains in non-protected welds. E. G. VANDEN BOSCHE

Non-corroding and acid-resisting alloys. BO KALLING. *Tek. Ukeblad* **75**, 101–3 (1928).—A review. C. A. ROBAK

Some properties of protective films on metals. ERNEST S. HEDGES. *Chemistry and Industry* **50**, 21–5(1931).—A review of film properties is given, with special consideration of the work carried out by Evans and by the author. A theory of anodic polarization is offered, according to which OH ions are discharged simultaneously with other anions, such as SO_4 ions for instance, if a certain crit. c. d. is reached and more SO_4 ions are discharged than can be replaced. This has the effect of producing a layer of oxide or basic salt on the surface. The presence of SO_4 ions renders this film non-protective, but it has the effect of raising very greatly the effective c. d. at those areas of the electrode which are uncovered. The consequence will be that in some spots the discharge will consist of OH ions only, which give a perfectly continuous oxide film. The discontinuous film first formed will be thrown off the electrode by the subsequent evolution of O_2. LEOPOLD PESSEL

The mechanism of the suppression of corrosion velocity by colloids. W. BECK AND F. v. HESSERT. *Z. Elektrochem.* **37**, 11–20(1931).—The decrease in corrosion velocity of Fe in H_2O or strong acid solns. is due to the presence of hydrophilic colloids, and is dependent upon the type as well as the concn. of added colloid. The authors suggest the possibility of the formation of coagulation layers upon the surface of the metal, due to the action of the Fe ions upon the negatively charged particles of the hydrophilic colloid. The colloidal materials studied were agar, starch, silicic acid and gelatin, and the metals, "Armco," electrolytic, "carbonyl" and pure Fe. H. STOERTZ

Protection of large steel structures from rust. HENRY E. WEITKAMP. *Het Gas* **50**, 480–4(1930).—A review. B. J. C. VAN DER HORVEN

Initial corrosion rate of steels. H. O. FORREST, B. E. ROETHELI AND R. H. BROWN. *Ind. Eng. Chem.* **22**, 1197–9(1930).—Studies of corrosion rates in distd. water, of oxide-free, low-C, 14% Cr steel and of (18–8) Cr-Ni steels were made during the initial stages of corrosion. After 10 min. the rates for the Cr and Cr-Ni steels became essentially zero, while the rate for C steel decreased but slightly, indicating the formation of invisible, adherent, protective films on the resistant steels. A method for obtaining reproducible results is described. B. B. ROETHELI

Rust-free steels, their properties and preparation. E. HOUDREMONT. *Krupp. Monatsh.* **11**, 270–86(1930).—H. discusses the various types of stainless steels as classified under the headings martensitic, ferritic and austenitic steels. The system Fe–Cr–Ni is studied together with the effect of C upon it. A table is given contg. the range of C, Si, Mn, Cr, Ni, W, Mo and Cu in typical examples of these steels. The prepn. of V2A in a Siemens-Martin furnace and the prepn of a Cr steel by reduction of a Cr ore in a basic furnace are described. Heat treatment, hot and cold working and recrystn. are considered in relation to their effects upon mech. properties. H. S.

Behavior of rustless steel toward dilute sulfuric acid. J. FRITZ. *Krupp. Monatsh.* **11**, 267–9(1930).—Conclusions drawn by various investigators that rustless steel is attacked by H_2SO_4 are incorrect. If practical requirements are adjusted so that the passivity of the rustless steel can be maintained, it is possible to use it in many solns. contg. free H_2SO_4. H. STOERTZ

Influence of a small addition of copper on the corrosion resistance of structural steel. O. BAUER, O. VOGEL AND C. HOLTHAUS. *Mitt. der deut. Materialprüfsanstalt.* Sonderheft **XI** 25 pp.(1930). Extended abstract by V. V. KENDALL in *Metals & Alloys* **1**, 890–5(1930).—The samples covered a range of soft steels, structural steels and 0.25 to 0.35% C steels. The tests were conducted as follows: (*A*) at room temp., (1) in distd. H_2O, (2) in Spree River H_2O, (3) in North Sea H_2O, (4) in humic acid soln., (5) alternating wet and dry in (*a*) 1% NaCl soln. and (*b*) distd. H_2O, (6) in the atm., (7) in 1% H_2SO_4 and (8) in 1% HCl; (*B*) at temp. of 50°, (1) in distd. H_2O, (2) in Spree River H_2O, (3) in North Sea H_2O, (4) in humic acid soln. and (5) in 1% H_2SO_4. Data and graphs are given. A. J. MONACK

Corrosion of metals by phosphoric acid. PETER R. KOSTING AND CONRAD HEINS, JR. *Ind. Eng. Chem.* **23**, 140–50(1931).—Tables are given of corrosion rates of 52 metals and alloys with pure and crude phosphoric acid of various strengths. Notes on passivity and corrosion inhibitors present in H_3PO_4 are added. ANN NICHOLSON HIRD

Furnace for metallographic examination of specimens at high temperatures. B. A. ROGERS. *Metals & Alloys* **2**, 9–12(1931).—The furnace is described. Expts. with the furnace have shown that it is possible to observe marked surface changes upon some elements as these pass through certain allotropic transformations. Observations at a magnification of 50 to 75 diams. were conducted on samples heated above 1500° and at higher magnifications when the temp. did not exceed 1000°. Photographs were taken at magnifications of about 150 diams. for temps. up to 1000°. Ten photomicrographs are given. A. J. MONACK

Investigations on wearing in the Amsler machine. C. J. GUMMAR MALMBERG. *Jernkontorets Ann.* **114**, 572–92(1930).—Ring material for trolleys and railway coaches was used. Aside from the quality of the material, the amount of wear is shown to be dependent on (1) the total load, (2) the local strains, (3) the slippage and (4) the wearing distance. Standardization requires fixation of load (P), diam. (D), r. p. m. (n), and the time (T). In the actual runs, the test cylinders (60 mm. diam.) were turned out of wrought iron, while the whetting cylinders (60–55 mm. diam.) were punched from rolled rods which were not heat treated after the rolling. The diam. of the rolls was essentially of no influence between 35 and 50 mm., with 10% positive slippage, but the wear was only about 25% as great for 50 mm. as for 35 mm., with 170% negative slippage. Increasing C from 0.6 to 0.8% quadrupled the wear, but the min. wear was with 0.90%. The wear also increases with the slippage. Wear on the test cylinder and the whetting cylinder tends to run parallel. The wear decreases with increased Brinell hardness, and the total wear is a min. when the hardness of the test cylinder exceeds that of the other cylinder. Oil-hardened test cylinders wore down the whetting cylinder much more than did water-hardened test cylinders. Structure plays a large part in wearing resistance No great difficulty should be encountered in standardizing dimensions of the test piece, load, slippage, r. p. m. and duration of test. H. C. D.

Vanadium ores. ALPHONSE GILDEMEISTER and ÉMILE COMPAGNE. Fr. 692,654, June 24, 1929. Ores of V, particularly vanadates of Pb or other metals, are submitted in the presence of a suitable flux, to a regulated reducing action to obtain the heavy metals in the metallic state and the V in the form of the insol. trioxide.

Treating rare metal silicate ores. CHARLES V. IREDELL (to Westinghouse Lamp Co.) U. S. 1,791,272, Feb. 3. An ore such as zircon is heated with C to a sufficiently high temp. (suitably about 1900–2500°) to convert the Si and rare metal content into carbide compds. which are sepd. by dissolving the Zr carbide with dil. HNO$_3$.

Recovery of precious metals from solutions. H. WÖLBLING. Brit. 335,565, Feb. 2, 1929. Acid solns. contg. precious metals such as chlorides of Pt, Pd, Au or Ag obtained from ores and contg. also base metals such as Cu, Fe or Ni are brought into contact with active C, which adsorbs the precious metal compds. Strongly acid solns. are first dild. or partly neutralized. The adsorbed compds. may be recovered by the action of concd. HCl.

Vacuum and pressure filtration apparatus suitable for metallurgical pulps, etc. JOHN T. SHIMMIN. U. S. 1,791,251, Feb. 3. Structural features.

Preparation of oxide ores for reduction. V. J. J. DEFAYS. Belg. 370,110, June 30, 1930. A gas rich in CO is passed over the ore, heated to a suitable temp. to produce a deposit of C, which facilitates the subsequent reduction.

Zinc blende treatment. SOC. ANON. LA NOUVELLE MONTAGNE. Brit. 335,609, March 9, 1929. Zn blende, either raw or roasted, is sintered under forced draught in admixt. with $ZnSO_4$ in the proportion of about 3 mols. sulfate to 2 mols. sulfide in excess of the amt. of sulfide necessary to ensure combustion and a colloid such as gum or dextrin may also be added. Cf. *C. A.* **24**, 5012.

Metallurgical furnace suitable for heat-treating metal sheets, bars, packs, etc. FRANK A. FAHRENWALD. U. S. 1,791,404, Feb. 3. Horizontal shafts pass through the side walls of the furnace and actuate circular disks and eccentric conveyer rolls.

Supporting frame for metallurgical furnaces. DINGLER'SCHE MASCHINENFABRIK A.-G. Fr. 693,045, Mar. 29, 1930.

Rotary furnace for ore treatments such as roasting or reducing with gases. CARL P. DEBUCH. U. S. 1,791,403, Feb. 3.

Improvement in the construction and operation of blast furnaces. V. J. J. DEFAYS. Belg. 370,336, June 30, 1930. The air is blown into the furnace at a pressure considerably above atm. The direction of the air blasts is varied, either continuously or intermittently by appropriate mounting of the nozzles.

Blast furnace, etc., operation. VULCAN-FEUERUNG A.-G. Ger. 515,315, Sept. 6, 1927. The introduction of water into the combustion zone of blast furnaces, cupolas and other shaft furnaces is effected with the use of a solid, liquid or gaseous auxiliary substance, other than the blast, as a carrier. Coke is specified.

Gas burner for blast-furnace stoves or furnaces. WM. R. PAULSEN (to American Heat Economy Bureau). U. S. 1,791,011, Feb. 3.

Drying air for furnace blasts. GÜNTHER MALYOTH. Ger. 515,216, Oct. 5, 1926.

The air is led over CaC_2. The mixt. of air and C_2H_2 thus obtained may be preheated and supplied as such to the furnace, or the C_2H_2 may be burnt, thereby regenerating one half of the moisture initially present in the air. Cf. *C. A.* **24**, 5013.

Tuyère for cupola furnaces. FRIEDRICH SCHINKE. Ger. 515,239, Mar. 21, 1929.

Bessemer process of making steel. FRANK W. DAVIS (to S. G. Allen Trustee to F. W. Davis). Can. 308,761, Feb. 17, 1931. The Bessemer process of making steel with non-Bessemer pig consists in detg. the net blow heat required and then proportioning the amt. of O to the amt. of inert gases in the blast so as to reduce the heat in the waste to a point which will give the blow heat required.

Casting ingots. T. BRINKMANN. Brit. 335,538, March 8, 1929. Mech. features.

Two-part ingot mold. SIEGFRIED JUNGHANS. Ger. 514,360, Jan. 8, 1929.

Ingot mold and hot-top construction. H. J. DARLINGTON (to W. M. Charman). Brit. 335,480, Dec. 31, 1928.

Apparatus for melting metal waste. HIRSCH, KUPFER- UND MESSINGWERKE A.-G. (Otto Götze, inventor). Ger. 514,442, Jan. 20, 1929.

Rare metals. FANSTEEL PRODUCTS CO., INC. Fr. 693,417, April 5, 1930. Difficultly fusible rare metals, particularly Ta, are freed from C which they contain as impurities by mixing the metal with a convenient amt of an oxide of an element which volatilizes at a temp. lower than the m. p. of the metal, the mixt. being afterward heated under vacuum to a temp. at which the C oxidizes and at which the residue left by the oxide volatilizes. The oxide used may be MgO.

Sheet aluminum. VEREINIGTE SILBERHAMMERWERKE HETZEL & CO. Fr. 693,869, Apr. 14, 1930. Sheet Al which is resistant to corrosion is made by welding into one whole, 2 or more laminated plates of Al and afterward transforming into sheets by rolling.

Tin. SOC. D'ÉLECTROCHIMIE, D'ÉLECTROMÉTALLURGIE ET DES ACIÉRIES ÉLECTRIQUES D'UGINE. Fr 692,640, June 22, 1929. In extg. Sn from its ores, alloys or slags, an auxiliary element contg. a proportion of Si which allows the formation of an Fe silicide unattacked by HCl or by an acid soln. of $SnCl_2$, is added to the initial charge.

Removing lead from metals. DUDZEELE CORP. OF AMERICA. Fr. 692,721. Mar. 25, 1930. Layers of Pb are removed from metal objects by immersing the objects in a warm acid soln. of one or more chlorides, *e. g.*, a soln. of NaCl contg. H_2SO_4 or HCl or a soln. contg. $FeCl_3$ and $NaNO_3$.

Lead containing phosphorus in small proportion. AMERICAN MACHINE & FOUNDRY CO. Brit. 335,545, March 19, 1929. A soldering, metal coating or deoxidized lead is prepd. with a content of P (which may be 0.01–0.03%) predetd. in accord with the rate of oxidation and the O content of the metals with which it is to be used in contact.

Magnetic iron and steel. VEREINIGTE STAHLWERKE A.-G. Fr. 693,602, April 9, 1930. Fe or steel free from magnetic aging and to be used as magnetic material is made by lowering the absorption of O and (or) deoxidizing the steel in known manner.

Cementation of steel. H. J. SCHIFFLER. Ger. 514,479, Mar. 19, 1927. Absorption of C in an amt. above the eutectic ratio is hindered by using steel contg. 0.4–4% of Al.

Rustless steel. GEORG MÜLLER. Fr. 692,887, Mar. 28, 1930. A rustless steel contains Cr 0.1–1, Cu 0.25–0.5, Ni 0.04–0.25 and W 0.01–0.05% and is free from Si. The added metals are introduced in the form of an alloy with Fe contg. Cr 20–30, W 5–6, Ni 6–10, Cu 10–15 and C (present in the form of carbide) 2.5–3%.

Treating surfaces of metals such as iron in order to prevent rusting. EARL K. WALLACE (to Rust Prevention Chemical Co.). U. S. 1,790,960, Feb. 3. The surface is treated with a mixt. formed of pure H_3PO_4 42.5, water 56 and casein 1.5%.

System of magnetic testing to determine properties of railway car wheels, etc. CARL KINSLEY (to Magnetic Analysis Corp.). U. S. 1,790,819, Feb. 3

Alloy. VEREINIGTE STAHLWERKE A.-G. Fr. 692,743, Mar. 25, 1930. Hard alloys of the stellite kind, *i. e.*, having a basis of Co, Cr, W and C with or without Mo, Ni, Fe and Mn, are made by using over 2% of C in the form of graphite

Alloys. CAMILLE CONTAL. Fr. 692,634, June 21, 1929. See Ger. 491,815 (*C. A.* **24**, 2420).

Refractory alloys. SOCIÉTÉ ANON. DES ANCIENS ÉTABLISSEMENTS SKODA A PLZEN. Fr. 693,775, Apr. 11, 1930. Refractory Cr alloys are made by compensating the high C content by the simultaneous addn. of Al and Ti so that the critical points of the alloy are displaced above the max. temp. of use. Thus, an alloy may contain a max. of 40% of Cr, C 3, Al up to 15 and Ti up to 15%.

Refining alloys. I. G. FARBENIND. A.-G. Fr. 693,544, April 8, 1930. Alloys of Mg and Ce are refined by adding dehydrated $CeCl_3$ to the mixt. of salts used in the

refining, whereby any moisture in the salts reacts with the $CeCl_3$ and does not affect the Ce in the alloy.

Aluminum and its alloys. WILHELM NEUMANN. Fr. 692,538, Mar. 21, 1930. Al or its alloys is obtained by the electrothermal reduction of Al_2O_3, clay, kaolin, bauxite, etc., the vapor tension of the Al being lowered by means of substances of high b. p. during the reduction operation. The Al and the added substances are sepd. by a phys. process and a distn. Metals of higher b. p. than Al or Si may be used.

Iron alloy containing copper, silicon and aluminum. BYRAMJI D. SAKLATWALLA. Fr. 693,418, April 5, 1930. See U. S. 1,781,527 (*C. A.* **25**, 66).

Iron-chromium-nickel-tungsten alloys. W. ROSENHAIN and C. H. M. JENKINS. Brit. 335,588, April 23, 1929. Alloys are described which contain over 40% Cr and Ni together (the ratio of the Cr to Ni being between 2:3 and 1:1), together with 1% of C or Si or both. The total Cr and Ni content may be about 50–50% and the W 4–20% or more

Lead alloy. ROBERT J. SHOEMAKER (to S. & T. Metal Co.). U. S. 1,791,148, Feb. 3. A tough, slightly hardened, corrosion-resistant alloy suitable for covering cables, pipes, etc., comprises Pb together with Ni 0.01–0.03, Ca 0.1–0.3, Sn 0.25–0.5 and Al 0.02–0.1%.

Magnesium alloys. I. G. FARBENIND. A.-G. Fr. 693,204, April 2, 1930. The properties of alloys having a high content of Mg are improved by a heat treatment which increases the soly of the materials in the alloy, followed by a cooling strongly retarded by artificial means, particularly in the zone from 300–100°, the duration of the cooling in this zone being at least 3 hrs. Cf. *C. A.* **23**, 678, 1214.

Optical mirrors from metals or their alloys. I. G. FARBENIND. A.-G. Fr. 693,816, April 12, 1930. Metallic mirrors of a high and uniform reflecting power for all wave lengths are formed by one or more layers of different metals or their alloys, which are chosen so that the low reflecting power of one constituent for a certain part of the spectrum is compensated by the high reflecting power of another constituent Ag along with Al, Si or Ni is mentioned as suitable.

Salt baths for annealing metals. W. FREY & Co. Ger. 514,366, Jan. 31, 1930. The baths consist of, or contain, NaCl, K_2SO_4, and Na_2CO_3 (or K_2CO_3) in such amts that the ratio Na:K is less than 1. The baths may contain also borax or Na_3PO_4 up to 6, alk. earth oxides or carbonates up to 10 and $NaNO_3$ 0.1–0.2%. An example given is NaCl 28, K_2SO_4 41.5, K_2CO_3 21, borax 4.5, $MgCO_3$ 2.5 and $CaCO_3$ 2.5%. The baths are particularly intended for objects of noble metals or their alloys.

Method of annealing large metal blocks by electric induction heating. C. LORENZ A.-G. (Wilhelm Fischer, inventor). Ger. 515,013, July 3, 1928.

10 ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Methane synthesis from carbon monoxide and water vapor. P. PASCAL AND E. BOTOLFSEN. *J. usines gaz* **54**, 467–8(1930); cf. *C. A.* **24**, 5282.—CO and H_2O give quant. yields of CH_4 and CO_2 in the presence of NiO at 250°, and practical yields up to 275°. At higher temps. equil. mixts. of CH_4 and H_2 are formed, until at 750° H_2 is quantitatively obtained. K. H. ENGEL

Properties of conjugated compounds. XI. Addition of hydrogen bromide to β,γ- and α,δ-dimethylbutadiene. ERNEST H. FARMER AND FREDERICK C. B. MARSHALL. *J. Chem. Soc.* 1931, 129–37; cf. *C. A.* **24**, 5284.—The mode of addn. of HBr to β,γ-dimethylbutadiene (I) has been studied by Bergmann (*C. A.* **17**, 1420) and by Claisen (*C. A.* **17**, 1619); B. states that I yields a stable α,δ-compd., $Me_2CBrCMe:CH_2$ (II), with 1 mol. HBr, while C. concludes that, although an unstable II is intermediately formed, the stable product is the α,δ-compd., $Me_2C:CMeCH_2Br$ (III). The chem evidence obtained in this study by the degradation of a no. of distd. and undistd specimens of the addn. product of HBr to I points unmistakably to the fact that the primarily formed product (even when addn. is effected at —20° in the absence of excess of HBr) is III; it also appears to be the sole product, although the complete absence of very small proportions of II could not be asserted. The α,δ-isomer gives a mixt. of $MeCH_2CHBrCH:CHMe$ (IV) and $MeCH_2CH:CHCHMeBr$ (V), as shown by conversion into the glycols and mono- and dibasic acids. The 3rd isomer was absent, showing that α,β-addn. takes place in only 1 of 2 possible ways The ratio of IV to V in the reaction product, as shown by the ratio of AcOH to $EtCO_2H$ formed, is approx.

90:10; this figure agrees roughly with the highest estimate of the proportion of AcH produced by ozonolysis of the hydrobromide. It is clear that the manner in which the alkylbutadienes add HBr varies, as it does for other sym. and unsym. addenda, with the position of substituent groups in the unsatd. chain. At present there is nothing to indicate the order of events in the 2-fold process of addendum-attachment and addendum-partition. C. J. WEST

Mercaptan chemistry. WILLIAM M. MALISOFF, ERNEST M. MARKS AND FRED G. HESS. *Chem. Reviews* **7**, 493–547(1930).—A crit. presentation and discussion of the SH compds. under the following headings: (1) phys. characteristics, (2) chem. characteristics, (3) methods of prepn. and purification, (4) detection and detn., (5) special interest attaching to the substances, (6) research problems. Approx. 600 references are given. G. TOENNIES

Nitrosites and nitrosates. LYDIA MONTI. *Gazz. chim. ital.* **60**, 787 97(1930).—The present paper deals with the prepn. of new nitrosates and nitrosites of octylene (I), diisobutylene (II) and hexadecylene (III), the formation of addn. products between these hydrocarbons and N_2O_4 and the decompn. of the nitrosates and nitrosites by heating in an inert gas. The literature describes only the nitrosates and nitrosites of the lowest members of the olefin hydrocarbons up to amylene (cf. Yegorov, *C. A.* **7**, 1477; Wallach, *C. A.* **9**, 1458). Following the usual method of prepn., the final products from I, II and III are yellow oils with the odor of fatty acids, and in certain cases the acids were identified. This formation of acid is attributed to the direct oxidizing action of N_2O_4 or to decompn. with autoxidation which nitrosates and nitrosites (formed at first) undergo spontaneously at room temp (cf. Schaarschmidt and Hoffmeier, *C. A.* **19**, 2634). The expts. prove that addn. products are formed. The gases evolved in the decompn. of the nitrosates and nitrosites contained in all cases N, NO and CO_2 and no othe gases in any appreciable quantity (cf. Schaarschmidt and Hoffmeier, *loc. cit.*, Sommer, *Ber.* **29**, 357(1896)). The formation of N and CO_2 indicates autoxidation and destruction of the mol. The quant. results are of special interest, for though the components are always the same, the proportions of the gases vary greatly One of the chief aims in the investigation is to develop a reliable *method for distinguishing nitrosates from nitrosites.* I was prepd. by refluxing *sec*-octyl iodide (100 g.) with alc. NaOH (25 g. in 500 cc.) for 10–2 hrs., pouring into a large vol. of water, drying the sepd. oil with $CaCl_2$, rectifying and recovering the 121–3° fraction. II was prepd. by the method of Butlerow (*Ann.* **189**, 44(1877)) and III by the method of Bertholet and Péan. In numerous expts. nitrous vapors (from As_2O_3 and HNO_3 of d 1.38) were bubbled through solns. of III in Et_2O or AcOH (6–10 parts of solvent). The liquid became green, but only under certain conditions in AcOH was a cryst. *compd.*, m. 66 7°, obtained in too small quantity to be analyzed. When the solvents were evapd. at room temp., thick yellow-green oils were obtained, and these dissolved in Et_2O, washed with 5 6% aq. Na_2CO_3, the alk. ext acidified with dil. HCl, extd. with Et_2O, the ext. evapd., the residual oil crystd. by cooling, dissolved in 95% EtOH, neutralized with alc. NaOH (phenolphthalein), alc. $AgNO_3$ added, warmed, filtered, the residue washed with EtOH, dissolved in NH_4OH, evapd., the ppt. washed and dried *in vacuo*, yields *Ag pentadecylate*. When the crude oil is let stand several months $(CO_2H)_2$ is deposited (Schaarschmidt has obtained $(CO_2H)_2$ by the slow action of N_2O_4 on satd. aliphatic hydrocarbons: cf. *Z. angew. Chem.* **37**, 938(1924); cf. *C. A.* **18**, 2138). Similar results were obtained by treating cold liquid N_2O_4 by attempting to prep. the addn. product with $AmNO_2$ and HNO_3, by treating III in an inert solvent with $NaNO_2$ and H_2SO_4, and by absorbing N_2O_4 in III under slight pressure at room temp. I and II also gave similar results. The oil from I contained fatty acids, but no Ag salt in a pure enough form to be analyzed was obtained. Here, too, $(CO_2H)_2$ was formed on long standing. With II a thick blue liquid was obtained. Thus, dil. H_2SO_4 (7 cc. concd. H_2SO_4 in 40 cc. water) added to II (8 g.) in ligroin (40 cc.), made ice cold, aq. $NaNO_2$ (10 g. in 20 cc.) added dropwise, the aq. part removed, the ligroin soln. evapd. *in vacuo* over CaO and paraffin, yields a blue liquid which after 8–10 days becomes a greenish yellow thick oil. Treating this oil in the same way as that from III, a *Ag salt* contg. 59.8% Ag was obtained, probably a mixt. of salts. Similar blue liquids were obtained from I and III. The d. of these products is over 1, they do not react with water and they give the Liebermann reaction. They are also formed by bubbling nitrous vapors (from As_2O_3 and HNO_3 of d. 1.38) into ice-cold I, II or III without solvent, stopping the reaction when the liquid has become dark blue, washing the product with water and sepg. by difference in d. The stability of the products varies with the nature of the hydrocarbon. That from II is the most stable, and the color lasts for several days. That from III is [illegible]

after a few hrs. The mol. wt. of the product from II was 179.2, which agrees fairly well with that for the nitrosite $C_8H_{16}O_3N_2$. The formation of addn. products was also proved by detn. of the quantity of N_2O_4 by II at room temp. Quant. data on the absorption of N_2O_4 by I, II and III at room temp. show in all 3 cases absorption which corresponds fairly closely with the addn. of 1 mol. of hydrocarbon with 1 mol. of N_2O_4. That true addn. products are formed is proved by mol.-wt. detns. Thus the mol. wt. of the product from III was 304 (316 calcd. for $C_{16}H_{32}N_2O_4$). A study was then made of the decompn. of *nitrosites and nitrosates*, for which purpose amylene nitrosate (IV) and the isomers styrene α-nitrosite (V) and styrene β-nitrosite (VI) were chosen, for these can be obtained in a very pure form. Further expts. will deal with other analogous compds. IV was prepd. by the method of Wallach (cf. *Ann.* **241**, 292(1887)) and V and VI by the methods of Wieland (cf. *Ber.* **36**, 2559(1903)). The *app.* for their decompn., which is described in detail and illustrated, allows heating of the nitrosate or nitrosite in the dry state in a current of inert gas (CO_2 or N). IV was thus heated at 90–5°, V at 100–25° and VI at 125–35°. In all 3 cases, N, NO and H_2O were evolved, and in no case was any appreciable quantity of a higher oxide of N, of O or of a combustible gas detected. CO_2 was evolved in considerable quantity. The following data give the % N (by wt.) evolved, the % NO evolved, the % total N evolved and the ratio: % N evolved/% N in compd., resp., for IV, V and VI: IV, 5.84, 2.50, 7.00, 0.405; V, 3.28, 6.93, 6.51, 0.418; VI, 4.04, 4.85, 6.30, 0.405. These results show that, although the components in the gaseous decompn. products are in all cases the same, the % compn. varies with the starting substance. In each case, the % N evolved in gaseous form (N + NO) is around 40% of the total N in IV, V or VI. The remaining 60% of solid decompn. products is composed of NO_2 compds., nitriles, etc.

C. C. Davis

Attempted preparation of methanetetrasulfonic acid. Frederic B. Kipping *J. Chem. Soc.* **1931**, 222–3. $I_2C(SO_3K)_2$ and K_2SO_3 in H_2O heated 4–5 hrs. give K methionate. $AcNH_2$ and H_2SO_4 (65 or 30% SO_3) at various temps. give $CH(SO_3K)_3$; with 10% SO_3 below 170–80° only AcOK could be isolated but at 210° K methionate was obtained in a poor yield.

C. J. West

Changes in properties of chemical compounds by complex formation. VI. Methylation of alcohols by diazomethane. Hans Meerwein and Gerhard Hinz *Ann* **484**, 1–25(1931). cf. *C. A.* **23**, 4189.—Aliphatically bound HO groups, as far as is known, do not react with CH_2N_2 (I). The following results were obtained with 0.5% EtOH-I at 0° (cc. N_2 in 1 min.): EtOH, 0.3; PrOH, 0.1; iso-PrOH, 0.18; BuOH, 0.18. Sufficient BuOH does not react with I in 30 hrs. to make the method useful for the prepn. of the ether. Since it would appear that an activation of the HO group might be brought about by complex formation or by the introduction of a polar or easily polarized group in the neighborhood of the HO group, a study of the latter possibility was undertaken. The following results indicate that this is the case and that the alcs. studied were more or less easily methylated by I. In general, the reaction was carried out by passing the I directly into the alc. Ethers retard the methylation in all cases and for this reason the reaction does not go to completion, the resulting ether preventing further methylation. $PhCH_2OH$ gives about 13% of the Me ether. $(CH_2OH)_2$ and its mono-Me ether scarcely react with I. $HOCH_2CH_2OAc$ in EtOH gives a mixt. of AcOEt, $HOCH_2CH_2OMe$, $MeOCH_2CH_2OAc$ and $(CH_2OH)_2$. Without a solvent the yield of the Me ether was about 12%; AcOMe(?) was also formed, although no explanation of its formation can be given. α-Monoacetin gives 25% of the *mono-Me ether*, b_{18} 126–9°, and some di-Me ether, b_{18} 100–10°. $(CH_2)_2O$ (30 g.) and 42 g. Cl_3CCO_2H give 15 g. of *trichloroacetylglycol* (II), b_{12} 130–40°; with I 12 g. II gives 5 g. of the *Me ether*, $Cl_3CC(OCH_2)_2OMe$, m. 77–8°, which is not changed by boiling H_2O or *N* NaOH but splits off Cl_3CCO_2H with 0.25 *N* HNO_3. $ClCH_2CH_2OH$ (15 g.) gives 8 g. of the Me ether, m. 91°. $ClCH_2CH(OH)CH_2OH$ (30 g.) gives 2.5 g. of the *Me ether*, b. 171–2°, d_0^4 1.1832, and 2.3 g. of the di-Me ether; with twice the amt. of I there results 2 and 12 g., resp. $(CH_2Cl)_2CHOH$ (30 g.) gives 26 g. of the Me ether, b. 159.5–61.5°. $HOCH_2CH_2CN$ and I react vigorously, giving in addn. to the *Me ether* (III), b. 162–4°, basic compds. with a C_5H_5N odor. MeO detns. indicate a 52% yield of III, although but 25% could be obtained pure. There was also isolated a *compd.*, $C_4H_7ON_3$, as the *HCl salt*. MeCH(OH)CN gives about 20% of the *Me ether*, b. 113–5°, d_4^{20} 0.8942, n_D^{20} 1.3825. Me_2CO, MeEtCO and $Me_2C.O.CH_2$. $AcCH_2OH$ gives only a small amt. of the Me ether, the principal product (50–60%) being $EtCOCH_2OH$. $BzCH_2OH$ behaves in a similar manner, giving *phenylacetylcarbinol*, bu

140–5°. With 20 g. $HOCH_2CH_2Cl$ as a catalyst, 20 g. PrOH and 8 g. I give 5 g. PrOMe and 5.6 g. $MeOCH_2CH_2Cl$. BuOH (20 g.), 10 g. $(ClCH_2)_2CHOH$ and 7 g. I give 3.2 g. BuOMe and 7 g. $(ClCH_2)_2CHOMe$. BuOH (10 g.), 7 g. Cl_3CCH_2OH and 5 g. I give 2.3 g. BuOMe and 4.8 g. Cl_3CCH_2OMe. Ten g. of a 5% BuOH-$ZnCl_2$ soln. and 2.2 g. I give 2.9 g. BuOMe; 20 g. of a 3.8% soln. of $FeCl_3$ in BuOH and 7 g. I give 6.1 g. BuOMe; 20 g. of a soln. of $MgCl_2$ in BuOH give 5 g. BuOMe. A 5% soln. of $Al(OEt)_3$ in BuOH and I give 83% of BuOMe; iso-PrOH gives 77% iso-PrOMe. $B(OEt)_3$ in EtOH (15 g. of 5% soln.) and I give 13 g. EtOMe; 0.69 g. $B(OMe)_3$ and 13.8 g. PrOH with 6 g. I give 4.1 g. PrOMe; iso-PrOH and BuOH are not methylated in the presence of B esters. $Sb(OBu)_3$ and BuOH give 73% of BuOMe; iso-PrOH scarcely reacts with I in the presence of $(iso\text{-}PrO)_3Sb$. C. J. West

Some aliphatic compounds of arsenic. W. J. Cecil Dyke, Gwyn Davies and Wm. J. Jones. *J. Chem. Soc.* **1931**, 185–8.—Pr_3As b_{17} 84°, b_{27} 92°, b_{79} 113°, which consts. are related by the equation $\log_{10} p = 3215/(t + 273)$. Exposed to the air, the arsine gradually deposits the oxide, also prepd. by shaking the arsine with HgO or the dibromide with Ag_2O. *Tributylarsine oxide*, pasty crystals, and the *Am deriv.* were thus prepd. *Tripropyl-* and *triisobutylarsine sulfides* crystallize as long needles Pr_3AsBr_2 and Ag_2SO_4 in EtOH give *tripropylarsine sulfate*, m. 84°. *Dichlorides* result from the arsine and Cl in CCl_4; *tri-Pr deriv.*, m. 84°, *tri-Bu deriv.*, m. 40°; *tri-iso-Bu deriv.*, m. 130°; *tri-Am deriv.*, sweet smelling liquid. The *dibromides*, prepd. similarly, are highly hygroscopic; Br is expelled by Cl, HNO_3 or H_2SO_4, *tri-Pr deriv.*, m. 95°; *tri-Bu deriv.*, m. 55°; *tri-iso-Bu deriv.*, m. 135°, *tri-Am deriv.*, liquid. The *diiodides* are formed in light petroleum, they become brown on exposure to the air; *tri-Pr deriv.*, m. about 130°, *tri-Bu deriv.*, m. 124°; *tri-iso-Bu deriv.*, m. 117–9°. $HgCl_2$ gives compds. of the general formula $R_3As.HgCl_2$, which may be recrystd. from EtOH; *tri-Pr deriv.*, m. 106°; *tri-Bu deriv.*, m. 70°; *tri-iso-Bu deriv.*, m. 158°. The arsines and MeI in Et_2O give methiodides; *methyltriethylarsonium iodide*, m. 270°; *tri-Pr deriv.*, m. 204°, *tri-iso-Bu deriv.*, m. 254°; in less pure condition were prepd. the *tri-Bu* and *tri-Am derivs.*, also *ethyltributylarsonium iodide*, m. about 107°. *Methyltripropylarsonium chloroplatinate*, m. 219° (decompn.); *tri-iso-Bu deriv.*, orange, m. 224° (decompn.); *tri-Am deriv.*, orange, m. 114°. The arsine methiodides and CdI_2 give the arsonium cadmi-iodides, best crystd. from EtOH; *methyltriethylarsonium cadmi-iodide*, $2MeEt_3AsI.CdI_2$, m. 283°, *tri-Pr deriv.*, m. 279°; *tri-Bu deriv.*, m. 100°; *tri-iso-Bu deriv.*, m. 138°. *Methyltripropylarsonium mercurichloride*, $MePr_3AsCl.HgCl_2$, m. 141°. *Methyltriethylarsonium mercuriiodide*, m. 61°, *tri-Pr deriv.*, m. 90°, *tri-Bu deriv.*, m. 76°; *tri-iso-Bu deriv.*, m. 117°. C. J. West

Parachor and chemical constitution. XVI. Silicon compounds. Samuel Sugden and Henry Wilkins. *J. Chem. Soc.* **1931**, 126–8; cf. *C. A.* **24**, 2651.—$Si(OMe)_4$, b_{759} 121·2° (all b. p. cor.), d_4^{23} 1.032, γ^{18} 24.98, parachor (*P*) 330.9, d_4^t 1.067 − 0.00155*t*. $Si(OEt)_4$, b_{756} 165.3–5.8°, d_4^{17} 0.933, d_4^t = 0.957 − 0.00135*t*, $\gamma^{16.5}$ 22.21, *P* 487.6. $SiEt_4$, for which a method of prepn. is given, b_{754} 153°, d_4^{12} 0.7563, d_4^t = 0.7818 − 0.000791*t*, γ^{12} 23.69, *P* 412.1. $SiPr_4$, b_{751} 213.5°, $d_4^{24.5}$ 0.7809, d_4^t 0.7990 − 0.0007272*t*, γ^{14} 24.65, *P* 565.3. $SiPh_4$, m. 234°, $d_4^{251.5}$ 0.937, d_4^t 0.983 − 0.000883 (*t* − 200), γ^{245} 23.70, *P* 787.5. The mean atomic *P* for Si is 27.8. Various values are given for d. and γ for these compds. C. J. West

Preparation of fatty acids. R. Lukeš. *Chem Listy* **24**, 197–200·1930).—A general method of synthesis of fatty acids from alcs. contg. 4 C atoms less than the desired acid is as follows: The alc. is converted into the alkyl bromide, and this is combined with Mg to yield the corresponding Grignard reagent, which reacts with *N*-methylsuccinimide to yield a 1-methyl-5-alkylpyrrol-2-one. This on hydrolysis yields a γ-keto acid possessing 4 C atoms more than the original alc., and this on electrolytic reduction yields the corresponding fatty acid. Hexoic, heptoic, octoic, nonoic and decoic acids have been prepd. in this way. The following hitherto unknown intermediate products are described: *1-methyl-5-amylpyrrol-2-one*, b_{10} 143–8°; *1-methyl-5-hexylpyrrol-2-one*, b_{10} 148–50°; *γ-ketononoic acid*, m. 69°; and *γ-ketodecoic acid*, m. 70–1°. B. C. A.

The mechanism of the decomposition of alkaline chlorohydrins. Lennart Smith. *Z. physik. Chem.*, Abt. A, **152**, 153–6(1931).—Doubt that this reaction is not monomol. seems not to have been well founded, for S., by using pure samples, has obtained good consts. for $(CH_2OH)_2$ and $Me(CH_2OH)_2$. V. F. Harrington

Formins of glycerol. P. A. Dubois. *Thesis.* Paris, 1929; *J. pharm. chim.* [8],**12**, 478–9(1930).—The objective was a rational and practical method of prepg. *allyl alc.* (I). Summary: (1) The mechanism of the formation of I, starting from HCO_2H and glycerol, is different from that when $(CO_2H)_2$ is used. (2) The esterification of

glycerol by HCO_2H leads principally to the formation of diesters. (3) HCO_2H seems to act more easily on the secondary alc. function of glycerol since the esters which predominate among the isomers of the same degree in the reaction mixt., are 2-monoformin and 1,2-diformin. (4) When esterification is pushed to the diformin stage, a yield of 70% I is easily obtained. S. WALDBOTT

A new form of the two antipodal rhamnitols. F. VALENTIN. *Collection Czechoslov. Chem. Comm.* 2, 689–95(1930).—Hydrated sugar alcs. having definite compn. and enantiomorphic cryst. forms have been prepd. for the first time. *l*-Rhamnitol formed by reduction of ordinary rhamnose with 3% Na-Hg and crystd. slowly from dil. H_2O soln. forms the trihydrate (I), m. 69°, $[\alpha]_D$ 8.83°. The H_2O of crystn. was detd. by drying at 100° *in vacuo*. Crystals of *d*-rhamnitol trihydrate (II), m. 69°, $[\alpha]_D$ −8.89°, were obtained similarly from *d*-rhamnose (see *C. A.* **25**, 84). I is rhombic, $a:b:c$, 0.9947:1:1.1750. The measured angle between the optic axes for Na light is 82.75°. The indices of refraction are α_{Na} (calcd.) 1.44, β_{Na} 1.492, γ_{Na} 1.505. The axial ratios and optical properties of II are the same JANET E. AUSTIN

Dipentaerythritol. WALTER FRIEDERICH AND WILHELM BRÜN. *Ber.* **63B**, 2681–90 (1930).—According to Ger. pat. 390,622, pentaerythritol (I) is prepd. by adding to AcH and 4 mols. HCHO in dil. aq. soln. at 15° 1 equiv. alkali or alk. earth hydroxide in the course of 1 hr. and slowly raising the temp. to 45° during the next hr. The m. p. of the crude product obtained by evapg. the reaction mixt. is raised to about 240° by crystn. from H_2O but again falls on further crystn. It was concluded that I is accompanied by an impurity which is less sol. in H_2O. This by-product has now been shown to be the ether, *dipentaerythritol*, $O[CH_2C(CH_2OH)_3]_2$ (II). Since the I and II cannot be sepd. by crystn., the crude product was nitrated and the nitrates sepd. through their different soly. in Me_2CO. Treatment of the nitration product with Me_2CO leaves undissolved almost pure I tetranitrate (III), the last traces of which are pptd. by cautious addn. of H_2O to the Me_2CO soln. This produces 2 layers: a H_2O-Me_2CO mixt. contg. a little II *hexanitrate* (IV), and a satd. soln. of almost pure IV in Me_2CO and a little H_2O. The latter stirred into 8–10 vols. alc. yields first a yellowish brown sirup and then white crystals, and the sirup, repptd. from Me_2CO with alc., gives a pure white product which is recrystd. from alc. *in vacuo*. The IV cannot be sapond. with alc. KOH because of the oxidizing action of the resulting KNO_3 on the II, but hydrolysis was effected with Zn and HCl or, better, with cryst. Na_2S in boiling Me_2CO-EtOH. The II (yield, 89%), m. 221°, mol. wt. in boiling H_2O 250, d_{15} 1.366, soly. in 100 parts H_2O 0.12 and 11.64 at 15° and 100°, in alc. 0.067 and 0.33 at 20° and the b. p., resp. Perfectly pure I, whose prepn. is to be described elsewhere, cannot be obtained by recrystn.; a prepn. which no longer gives the fuchsin-SO_2 test for II (see below) m. 260°; the m.-p. curve of mixts. with II falls steeply to a min at about 190° with 30% II and shows that an I m. 235°, which for practical purposes may be considered pure, contains 10% II. Radulescu's statement that the by-product m. 220° obtained in the prepn. of I can be converted into pure I, m. 254°, by treatment with alc. was not confirmed; the m. p of pure II was not changed in the slightest by several crystns. from alc. IV (95.7% from II slowly added to cold HNO_3 (d. 1.52) and treated with $^2/_3$ vol. concd. H_2SO_4), m. 75°, d_{15} 1.630 (cryst.), 1.617 (fused), mol wt. in freezing C_6H_6 522; the f.-p. curve of mixts. with III (m. 141°) is almost a straight line with no min. or max. *Hexaformate*, from II refluxed in concd. HCO_2H and fumed down twice with HCO_2H at 120°, yellow, m. 56°. *Hexaacetate*, from II, Ac_2O and NaOAc, heated under a reflux until a violent reaction sets in (yield, 54.8%), m. 73°, mol. wt. in C_6H_6 514. *Hexabenzoate*, from II, BzCl and NaOH below 40° (83.5% yield), m. 183°. *Hexatrityl ether* (97.3% from II and Ph_3CCl in C_5H_5N at 100°), m. 173°, decompd. by atm. moisture and completely hydrolyzed by boiling H_2O. Attempts to increase the yield of II by the use of other alk. condensing agents (KOH, $Ba(OH)_2$, $Pb(OH)_2$, $Zn(OH)_2$, Na_2CO_3) were unsuccessful; boiling for days with NaOH, $Ca(OH)_2$, HCO_2Na, $(HCO_2)_2Ca$, did not change the m. p. of pure I; fusion of I with K_2CO_3 yielded a brown resin contg. no II or other cryst. product. No II was formed when I was heated at 300° under a steam-jacketed head which permitted the H_2O to distil off and condensed the higher-boiling vapors back into the flask, nor when the I was heated at 300° in a sealed tube with 0.25 part H_2O. Pentaerythrose, condensed with AcH and HCHO in the most varied proportions, gave only ordinary crude I and in poorer yield than the method described above. The mixt. of glyceric aldehyde and $CO(CH_2OH)_2$ formed by oxidation of glycerol yielded no cryst. products. $MeCH:CHCHO$ with 8 mols. HCHO and 1 equiv. CaO gave I, m. 248–52°, in 64% yield as detd. by conversion into III. $CH_2:CHCHO$ with 3 mols. HCHO and 0.5 mol. $Ca(OH)_2$ gave 63.4% I. Expts. with AcH, 0.5 mol. $Ca(OH)_2$ and varying amts. (1–8 mols.)

of HCHO showed that the purest I (m. 258°) is obtained (in 73.5% yield) with 5 mols. HCHO and that the most favorable condition for the formation of II is 3 mols. HCHO; the I thus obtained m. 221° and contains 15% II. The compn. of II is established by the results of analyses and mol.-wt. detns. on II, its acetate and nitrate, the presence of 6 HO groups by Bz and Ac detns. on the benzoate and acetate, that 3 HO groups are present as CH_2OH by the formation of the trityl ether, and that II has a structure similar to I by the decompn. of the formate at 270° into CO and II. As regards the union of the two I residues and the 7th O atom, II does not add Br and hence contains no unsatd. union; it does not reduce Fehling soln., indicating the absence of a CHO group; it does not react with $PhNHNH_2$ and is not reduced by Al-Hg; it cannot be a formal, as it does not deposit C with concd. HI. That it is an anhydride derived from 2 mols. I is shown by the fact that when treated with HNO_3 (d. 1.13) it reddens fuchsin-SO_2 and gives the same white insol. oxidation product, yielding $O(CH_2CH:NNHPh)_2$, m. 109°, which Tollens and Wigand had obtained in the same way from I. This oxidation product dissolves on long heating with 20% H_2SO_4 and yields a phenylhydrazone m. 123°, which, from its compn., is apparently the pure $O(CH_2CH:NNHPh)_2$. The oxidation product is therefore a polymer of $O(CH_2CHO)_2$. When *very carefully purified* I, m. 260°, is oxidized in the same way it does not redden fuchsin-SO_2 and forms no insol. product. $O(CH_2CHO)_2$, with the characteristic grouping $>CH_2.O.CH_2<$, is therefore formed only from II. This oxidation with HNO_3 and reaction with fuchsin-SO_2 also affords a convenient means of testing I for purity. Attempts to rupture the ether union in II with HBr or HI (d. 1.7) gave, even in sealed tubes, only a sirup, but with HI, P and a little Ac_2O was obtained a small amt. of needles, m. 106–7°, whose I content corresponded to that calcd. for the *diiodohydrin* of II. HI (d. 2.0), P and Ac_2O at 140° gave *pentaglycerol triiodide*, $MeC(CH_2I)_3$, m. 154° (yield, 50%), hydrolyzed by $N_2H_4.H_2O$ at 140° in an Fe pressure tube to $MeC(CH_2OH)_3$. C. A. R.

Purity and polymorphous transformation of pentaerythritol. L. EBERT. *Ber.* **64B**, 114–9(1931); cf. preceding abstr.—Repeated recrystn. of pentaerythritol (I) from different solvents does not free it from considerable quantities of a stubbornly adhering impurity. E. found that the best method of purification is very careful sublimation at 130° in a high vacuum. Sublimation for several days gave transparent cryst. deposits, some contg. clear, thin leaflets. These leaflets gave the highest values for the m. p., 259° (uncor.) and 260.5° (cor.). E. concludes that all previous work on I has probably been done with impure material. Some of the best crystals were studied in polarized light and were found to be uniaxial; others were optically homogeneous, but weakly biaxial. This contradiction needs explanation. At 179.5–180° tetragonal I, which shows double refraction, is transformed into a cubic modification which does not show double refraction. The transformation is reversible. (The changes undergone by I are described by E. in detail.) The cooling curve of I shows a small break at the m. p. and a marked break at the transformation point. The av. value for this latter point was found to be 179.5°. The heat of transformation is 3–4 times as large as the heat of fusion, which is so small that small quantities of impurities cause large depressions of the m. p. Impurities have practically no effect on the transformation point. LOUISE KELLEY

Propylenebisthioglycolic acid and propylenebissulfonacetic acid. J. A. REUTER-SKIÖLD. *J. prakt. Chem.* **129**, 121–8(1931).—$MeCHBrCH_2Br$ and Na_2S in EtOH at 40° give the mercaptan, which reacts with $ClCH_2CO_2H$ in NaOH at 0° to give *propylenebisthioglycolic acid* (I), m. 32–5°, very hygroscopic, purified through the *Cu salt*, light green needles, crystg. with 1 mol. H_2O; in CO_2 Cu_2O gives the salt $C_{14}H_{22}O_8S_4Cu$; *dianilide*. A partial resolution into optical antipodes was effected by crystn. of the neutral brucine or strychnine salt from H_2O. Oxidation of I with $KMnO_4$ gives *propylenebissulfonacetic acid*, m. 185–6°, decompd. by alkali to *2-propene-3-sulfonacetic acid*, isolated as the *Na salt;* the free acid could not be obtained pure. Bromination of the Na salt gives *hexabromodimethyl sulfone*, $(Br_3C)_2SO_2$, m. 131–2.5°. C. J. WEST

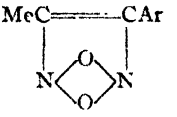
Preparation of prolylalanine and prolylpeptides. MAX FRANKEL AND SONJA KUE. *Biochem. Z.* **226**, 221–32(1930).—Detailed directions are given for the prepn. of allyl alc. in quantity and its conversion successively into allyl and trimethylene bromides. The latter is condensed with $NaCH(CO_2Et)_2$ and the product brominated and hydrolyzed to *α,δ-dibromovaleric acid*, m. 172–4°. PCl_5 converts this acid to its acid chloride, which is condensed with *dl*-alanine and the product treated with NH_3 to give prolylalanine. R. CHESTER ROBERTS

A new synthesis of serine. SUSIL K. MITRA. *J. Indian Chem. Soc.* **7**, 799–802 (1930).—A synthesis by Gabriel's method is described, followed by hydrolysis with

concd. HBr at 48°, or hot alc. KOH. To the cooled Na salt from 20 g. $C_6H_4(CO)_2NCH(CO_2Et)_2$ and 1.6 g. Na in Et_2O with the addn. of some EtOH, 9 g. of $ClCH_2OMe$ in 20 cc. Et_2O was added dropwise over a period of 2 hrs., giving 60% of *di-Et methoxymethylphthalimidomalonate*, $C_6H_4(CO)_2N(CH_2OMe)C(CO_2Et)_2$ (I), m. 127°. Ten g. of I and 50 cc. of HBr (d. 1.8), heated, in a sealed tube for 2 hrs., gave the free *acid* (II), m. 102°, in 50% yield. On heating 5 g. of II with 15 cc. of fuming HCl in a sealed tube on a water bath for 9 hrs., filtering off the $C_6H_4(COOH)_2$ formed, and extg. with Et_2O, an aq. soln. was produced which on concn. gave *serine·HCl* (III); yield 50%. III treated with moist Ag_2O gave free *serine*, m. 246°; *phenyl cyanate deriv.* m. 159°. The alk. hydrolysis of I with alc. KOH gave a K salt, $C_{13}H_{10}O_8NK_3$, which on acidification evolved CO_2, forming an oil, hydrolyzed by fuming HCl to III (55% yield)

C. R. Addinall

Osazone-forming groups. E Votoček. *Collection Czechoslov. Chem. Comm.* **2**, 681–8(1930).—The groups CH_2ClCO-, $-CHClCO-$, $CHCl_2CO-$, $-COCH_2NH_2$, $-COCH(NH_2)C-$, $-C(:NOH)C(:NOH)-$ and other N compds. formed from dicarboxyls form osazones. No oxidation of  occurs, the hydrazone being formed. CH_2ClCHO heated with 3 mols. $PhNHNH_2$ (I) in 96% EtOH in the presence of anhyd. AcOH forms *glyoxal phenylhydrazone* (II), m. 170°; $CH_2ClCOMe$ and $PhNH·NH_2AcOH$ (III) in H_2O soln. yield *methylglyoxal phenylosazone* (IV), m. 144–5°; $MeCHClCOEt$ with 3 mols. I in EtOH gave *acetylpropionyl phenylosazone* m. 164–5°; $CHCl_2CHO$ and I in abs. alc. form II; $CHCl_2COMe$ in alc with 2 mols. III and excess NaOAc forms IV. $[MeC(:NOH)]_2$, heated with HOAc, H_2O and 2 mols. of I, yields *diacetyl phenylhydrazone*, m. 240–1°; glucose semicarbazone, $PhNHNH_2$ HCl and NaOAc form ordinary glucosazone, m. 210°. Contrary to Neuberg's rule that secondary aromatic hydrazines easily furnish osazones with the group $-CCOCH_2OH$ and not with $CCH(OH)CHO$, it was found that in certain cases the secondary alc. group is easily oxidized. Thus, *diacetyl methylphenylosazone*, m. 96–7°, is formed by the action of $PhNMeNH_2$ HOAc on freshly distd. $MeCH(OH)COMe$ (V) in H_2O in CO_2 atm. or on Ac_2 (VI), and *diacetyl benzylphenylosazone*, m. 110–1°, by the action of $PhCH_2NPhNH_2$ on V in HOAc and H_2O or VI in alc. V with Ph_2NNH_2 H_2O and HOAc forms *diacetyl diphenylosazone*, m. 187°. J. E. A.



Dioximes. LXVIII. I De Paolini. *Gazz. chim. ital.* **60**, 700–4(1930); cf. *C. A.* **25**, 955.—In an earlier paper (Note LIX, *C. A.* **24**, 1632) it was shown that from $HOC(:NOH)C(:NOH)CO_2H$ (I) and Br is obtained a compd. (II) which is also formed from $HC(:NOH)C(:NOH)OH$ (III) and Br. A further study of the general behavior of hydroxamic acids ($RC(:NOH)OH$) which are hydrolyzed by Br to the corresponding RCO_2H acids (cf. Note XL, *C. A.* **21**, 1100) suggested that II may be formed by the action of Br on $HC(:NOH)CO_2H$ (IV) which is formed either thus: III + H_2O ⟶ IV + NH_2OH, or thus: I + H_2O ⟶ IV + NH_2OH + CO_2. By similar reasoning, II should be the final product of the reaction of $C(:NOH)[C(:NOH)OH]_2$ (V) and Br and of $HO_2C(:NOH)CO_2H$ (VI) and Br, which are both theoretically transformable into IV, thus: V VI Expts. confirm these concepts for by the action of Br on V, on I, on VI, on $HC(:NOH)C(:NOH)C(:NOH)OH$ and on IV, II is always formed. Its compn. and behavior indicate that II is *carbonyl bromide oxime* $Br_2C(:NOH)$. In all cases it is probably formed by the subsequent action of Br and IV, thus. IV + 4Br ⟶ II + 2HBr + CO_2, and the highest yield and the purest form of II is obtained directly from IV. II is most readily obtainable of any simple deriv. of C:NOH (VII), for it may be obtained directly: VII + 2Br ⟶ II, which also confirms its structure. IV is best prepd. by a method already described (cf. Note XLIV, *C. A.* **22**, 577). The best way to prep. II is to add Br water to ice-cold aq. IV, ext. with Et_2O, recrystallize from petr. ether and dry *in vacuo*. It then m. 70–1° (first softening). Heated with 20% HCl, II forms NH_2OH. Heated with $FeCl_3$, aq. II gives a red color and with $Cu(OAc)_2$ a green color, probably as a result of the formation of a $RC(:NOH)OH$ acid. With $NaNO_2$ and NaOH, II gives a red color, indicative of the formation of a nitrolic acid by substitution of a Br by a NO_2 group. With NH_4OH and then $FeCl_3$, II gives a violet-red color, probably a result of the substitution of Br by the NHOH group. Ice-cold aq. C:NONa, acidified with H_2SO_4, treated with an excess of Br-water, let stand several days, extd. with Et_2O, and the ext. evapd., gives a very small yield of impure II. The impurities were not

identified. Concd. aq. $Hg(NO_3)_2$ added to cold aq. II, steam-distd. and the distillate again steam-distd., yields dibromofuroxan, also formed from Br and $(C:NO)_2Hg$ by the Kekulé reaction (cf. Wieland, *Sammlung Chem.-Tech. Vorträge* **14**, 429(1909)). **LXIX.** G. Ponzio. *Ibid* 825 32.—The present paper shows that the behavior toward HCl in Et_2O of the 2 forms of some glyoximes does not agree with the structural configurations which would be assigned to them by the theory of Hantzsch and Werner. The majority of aromatic aldoximes exist in 2 forms, one of which can be isomerized to the other by HCl in Et_2O (cf. Porter, *Monograph on Molecular Rearrangements*, p. 34), whereas only a very few glyoximes have 2 or more forms. The present paper describes 2 more cases of the latter isomerism. Though there are too few expts. on the isomerism of glyoximes to warrant any general conclusions, some authors have attempted to extend to glyoximes the distinction made by Hantzsch for monoximes, *viz.*, that there are forms stable toward acids and forms stable toward bases. This has led to the alleged discovery of glyoxime forms which do not exist. P. has already shown the insufficiency of the Hantzsch theory, and in the present paper only the exptl. results of the action of HCl on the particular glyoximes and their behavior with Ni and $Ni(OAc)_2$ are given. They were transformed into the complex $Ni(DH)_2$ (where DH is the univalent residue after removal of a H atom from an oximino group of the glyoxime DH_2), both by Ni in the presence of water and by Ni^{++} ions in dil. AcOH. In conjunction with the expts. of earlier workers, the results show that HCl in Et_2O isomerizes a form (1) of benzil dioxime which does not give a $Ni(DH)_2$ complex to a form which does give this Ni complex; (2) of chloroglyoxime which does not give a $Ni(DH)_2$ complex to another form which likewise does not give the complex; (3) of phenylglyoxime which gives a $Ni(DH)_2$ complex to a form which does not give the complex, (4) of *p*-tolylglyoxime which does not give a $Ni(DH)_2$ complex to a form which does give the complex and (5) of *p*-tolylglyoxime which gives the $Ni(DH)_2$ complex to a form which does not give the complex. Even without taking into account the contradictions which arise from the configurations of the 2 forms of the glyoximes assigned in the past, and even assuming according to Hantzsch and Werner that the forms which give $Ni(DH)_2$ salts are always *anti*-forms and that the forms which do not give $Ni(DH)_2$ salts are *amphi*- or *syn*-forms, nevertheless the behavior of the different forms of 1 glyoxime cannot be explained by different spatial positions of the oximic OH group. HCl acts in some cases in the same way, and in other cases in different ways, on forms which must have the same configuration, and with α- and β-*p*-tolylglyoxime, which must have different configurations, HCl isomerizes the α-form to the β form and the β-form to the α-form. Dry HCl passed into ice-cold α-phenylglyoxime (I) in anhyd Et_2O, the ppt. washed with Et_2O and dried rapidly *in vacuo*, yields 100% of the *HCl salt* (II) of I, loses completely its HCl when kept in air or in a dry vacuum. I or II, dissolved in dil. NaOH, acidified with AcOH (or treated with NH_4Cl), and the ppt. recrystd. from EtOH, yields purified I, m. 168 72° (slight decompn.). The variability in the m. p. results from the fact that the heating causes its isomerization to β-phenylglyoxime (III), m. 180°. This isomerization begins at 160° or higher and is always accompanied by some decompn. When prepd. directly by oximation of $BzC(:NOH)H$ (IV) (cf. Note LVII, *C. A.* **24**, 845) without passing through II, I has the same properties, and when freed of III by treatment with $Ni(OAc)_2$ in AcOH and when crystd from EtOH, AcMe, $CHCl_3$, dil. EtOH or water, it m. 168-76° (slight decompn.). It may be concluded, therefore, that by the action of heat I isomerizes, even in the solid state, at 160 80° to III, so that it is impossible to assign to I a definite m. p. More on this subject is to be published later. Dry HCl passed into ice-cold III in anhyd. Et_2O until satd., let stand, the ppt. washed with Et_2O and dried rapidly *in vacuo*, yields II, from which, by the method already described, I (free of III) may be obtained. Taking into account the yield of the reaction, it must be concluded that HCl in Et_2O quantitatively isomerizes III into I, a reaction never before observed, and which represents the 1st case of an isomerization of a form which gives the $Ni(DH)_2$ complex to a form which does not give this complex. By utilizing the behavior of I and III toward HCl in Et_2O, extremely pure I can readily be obtained from mixts. of I and III, without having to resort to the elimination of III by means of the $Ni(DH)_2$ complex. It is only necessary to dissolve the product in anhyd. Et_2O and then to pass into the soln. a current of dry HCl. All the III isomerizes to I, which with that already in the mixt. ppts. as II. When further expts. now in progress are completed, the structure of I and II will be discussed, but for the present they cannot be regarded as geometrical isomers; in fact, by the hypothesis of a different spatial position of the oximic OH group it is impossible to explain why only I forms a HCl salt and crystallizes unaltered by cooling its boiling soln. in 6 *N*

NHOH, and why only aq. III attacks Ni, Co, Cu and Fe (cf. Note VI, *C. A.* **17**, 2268), or, in other words, why I has a basic function in which an oximic N atom becomes quinquevalent and III an acid function toward metals of the 8th group. The method of *prepn. of* I *and* III already described (cf. Note VI, *C. A.* **17**, 2268) should be modified as follows: Aq. $HONH_3Cl$ (5.3 g.) and aq. AcONa (11.8 g. in 15 cc.), added to hot alc. V (10 g. in 20 cc.), kept at 60–80° for 12 hrs. (p_H is 5.2–5.4), cooled, the ppt. (6.2 g. of a mixt. of 95% I and 5% III) dissolved in anhyd. Et_2O, made ice-cold, dry HCl passed through the soln., and the ppt. treated with dil. Na_2CO_3, yield 6 g. of pure **I.** The mother liquor, concd. to the point of crystn., yields on cooling 4 g. of a mixt. of 75% of III and 25% of I. The mixt. dissolved in boiling 50% EtOH, glacial AcOH added, excess hot 20% $Ni(OAc)_2$ added, the ppt. washed with EtOH, decompd. with HCl and extd. with Et_2O, yields 2.8 g. of **III.** To isolate the I which remains in the AcOH soln. from which the Ni complex of III seps., the soln. is made basic with NH_4OH, the ppt. is treated with dil. H_2SO_4 and extd. with Et_2O. This yields 1.2 g. of slightly colored **I.** Avogadro (cf. Notes XIII and XLII, *C. A.* **18**, 661; **21**, 1976) has prepd. α- and β-*p*-tolylglyoximes (V and VI, resp.). Dry HCl passed into V in ice-cold anhyd. Et_2O, does not ppt. a HCl salt, but 40% of V isomerizes to VI, and the latter is readily isolated as the Ni complex, $Ni(C_9H_9O_2N_2)_2$. Following the same procedure with VI, 60% of VI isomerizes to V. To isolate the V, the product is washed with Na_2CO_3, the solvent eliminated, the residue dissolved in boiling 50% EtOH, a little glacial AcOH added, excess $Ni(OAc)_2$ then added, the ppt. (Ni complex of VI) removed, the filtrate made alk. with NH_4OH, the ppt. treated with dil. H_2SO_4 and finally extd. with Et_2O. V apparently m. 170–1°, but it has no true m. p. since by the action of heat it isomerizes to VI. **LXX.** *Ibid* 886–93.—A better method for the *prepn. of* PhC(:NOH)-C(:NOH)Cl (I) than that previously described (Note VI, *C. A.* **17**, 2268; Note XXIV, *C. A.* **20**, 746) is to dissolve α- or β-phenylglyoxime (or their mixt. from the oximation of PhCOCH:NOH) in a min. of 98–9% AcOH, cool, pass into the soln. a slight excess of Cl, wash the ppt. with AcOH and dry at 70–80°. It m. 199–200°. I and BzCl (calcd. quantity), heated 1 hr. on a boiling water bath and the product recrystd. from $CHCl_3$, yields *2-benzoylphenylchloroglyoxime*, PhC(:NOBz)C(:NOH)Cl (II), m. 177–8° (slight decompn.), does not form an Ac deriv. with Ac_2O at room temp. II and excess BzCl, heated for a long time at 100° or boiled for a few min., ligroin added and the ppt. recrystd. from EtOH, yield *dibenzoylphenylchloroglyoxime* (III), m. 148–9°. III, dissolved in warm alc. NH_3, the solvent eliminated, the residue dissolved in dil. HCl, cryst. AcONa added and the ppt. recrystd. from water, yields β-phenylaminoglyoxime (IV) (cf. Note VI, *C. A.* **17**, 2268). II in Et_2O, agitated with a slight excess of 6 *N* NH_4OH for a short time, and the ppt. recrystd. from EtOH, yields *2-benzoyl-α-phenylaminoglyoxime*, PhC(:NOBz)C(:NOH)NH_2 (V), m. 171–2° (slight decompn.), insol. in cold dil. NaOH; in EtOH with $FeCl_3$ it gives a light violet-brown color which disappears when dild. with water. V, heated gently with 20% NaOH and a little EtOH, dild. with water and the ppt. recrystd. from water or very dil. EtOH, yields phenylaminofurazan (cf. Note X, *C. A.* **17**, 3875). The alk. mother liquor, neutralized with CO_2, extd. with Et_2O, the ext. evapd. and the residue recrystd. from a mixt. of Et_2O and petr. ether, yields α-phenylaminoglyoxime (VI) (cf. Note VI, *C. A.* **17**, 2268). Alc. II and a slight excess of $PhNH_2$, heated to boiling, dild. with water, acidified with dil. HCl, filtered (the residue is $BzNH_2$), NaOAc added to the filtrate and the ppt. recrystd. from $CHCl_3$, yield α-phenylaminophenylglyoxime (cf. Note VIII, *C. A.* **18**, 661). In the cold, $PhNH_2$ does not react with II. Cold IV, Ac_2O and fused AcONa yield, after crystn. of the product from EtOH, *2-benzoyl-N-acetyl-α-phenylaminoglyoxime*, PhC(:NOBz)C(:NOH)NHAc (VII), m. 190–1° (slight decompn.). That the Ac group is united with the amino N and not to the oximino O is shown by the fact that when VII is heated gently with 20% NaOH and a little EtOH phenylaminofurazan and its Ac deriv. are obtained. In conjunction with earlier expts. (cf. Notes XXXVII, LXIV and LXV, *C. A.* **21**, 1099; **25**, 79, 80), the present expts. show that when BzCl acts at 100° on chloroglyoximes, RC(:NOH)C(:NOH)Cl, where R is H, Me or Ph, the oximino H farthest from the Cl is first replaced by Bz, giving the RC(:NOBz)-C(:NOH)Cl, with which in turn excess BzCl forms RC(:NOBz)C(:NOBz)Cl. The constitution of V corresponds to VI, *i. e.*, it is a deriv. of a form of VI which in the free state is to be regarded as a labile form which is easily isomerized by fusion or by heating in dil. AcOH into IV, a stable form. Since I is transformed by NH_3 into IV, which is not isomerized by NH_3 to VI, in the benzoylation at 100° of I a 2-Bz deriv. is obtained of a form of I incapable of existing in the free state. This bears the same relation to the only known form of I as does VI to IV. HCl can isomerize 1 form of glyoxime to the other form (cf. Note LXIX, preceding abstract), so it is not impossible that a

similar reaction takes place in benzoylation with BzCl at 100°. Observations in the past on the behavior of acyl derivs. obtained from MeC(:NOH)C(:NOH)OH, PhC(:NOH)C(:NOH)OH, HC(:NOH)C(:NOH)Cl and HC(:NOH)C(:NOH)NH_2 have shown, however, that in many cases the acylation of glyoximes proceeds in an abnormal way, even aside from an isomerizing action of HCl. Accordingly, when 1 oximino H atom or both atoms in a glyoxime are replaced by 1 or 2 acyl groups, it is never certain that the acyl derivs. will be of the same form as that of the original compd., even if these acyl derivs. form again on hydrolysis the original form. Acylation is much less simple than is generally assumed, and the Hantzsch and Werner theory is wholly inadequate to explain the phenomena (cf. Notes LXIV and LXVI, *C. A.* **25**, 79, 80). On the assumption (based on the theory of Hantzsch and Werner) that glyoximes which form $Ni(DH)_2$ complexes have *anti*-configurations, and that the Cl of the C(:NOH)Cl group can become ionic only if it is in the *syn*-position to the oxime OH group, in the benzoylation at 100° of phenylchloroglyoxime with BzCl, the HCl liberated should bring about a spatial transposition and the passage from the *anti*- to the *amphi*-configuration: PhC(HON)—CCl(NOH) BzCl → PhC(NOBz)—CNH$_2$(NOH). Moreover, since II and NH_3 form V, phenylaminoglyoxime and its 2-Bz deriv. should be *amphi*-compds.: PhC(NOH)—CNH$_2$(NOH) → PhC(NOBz)—CNH$_2$(NOH). Because of the formation of III from II and of IV in turn from III, and since IV forms the $Ni(DH)_2$ complex and is (according to the Hantzsch and Werner theory) an anti-form PhC(HON)—CNH$_2$(NOH), HCl should under the same conditions bring about a spatial transposition: PhC(NOBz)—CCl(NOH) BzCl → PhC(BzON)—CCl(NOBz) opposite to the preceding transposition (in the 1st case the hydroximino OH group passes from the *syn*- to the *anti*-position with respect to Ph, and in the 2nd case the same OH returns from the *anti*- to the *syn*-position). The simplest explanation is that the NOH group in 1 glyoxime can (whatever the neighboring radical) assume 2 different structures, depending upon the reagent, *i. e.*, glyoximes react either as if they contained 2 NOH groups or as if they contained only 1 NOH group. In this way, it is easy to explain why phenylchloroglyoxime from VI and IV forms a di-Ac and di-Bz deriv., whereas VI, II and V cannot be acetylated in the NOH group in 1-position. LXXI. G. Ponzio and G. Longo. *Ibid* 893–9.—Expts. by earlier investigators on the action of EtMgI on the diphenyl peroxide and methylanisyl peroxide (I) (cf. Wieland and Semper, *C. A.* **2**, 1012), of PhMgBr on the methylpiperyl peroxide (II) (cf. Angeli, *C. A.* **11**, 794) and of MeMgI on II and of PhMgBr on I (cf. Bigiavi, *C. A.* **16**, 1394) showed the varying behavior of these peroxides and, furthermore, did not give any indication of the existence of the isomers of methylaryl peroxides $Me(C_2N_2O_3)Ar$ recently described by P. (cf. Notes L, LI, LIV, LX, LXI and LXII, *C. A.* **23**, 375, 3665; **24**, 363, 1633, 3488, 3774). It was therefore of interest to ascertain whether these new peroxides behave differently toward the Grignard reagent than do their isomers. Since the isomeric methylaryl peroxides are readily transformed to the other form by the action of heat, the reaction was in every case carried out at room temp. for a very short time instead of prolonged heating in C_6H_6. The expts. in the present paper confirm the indications of the earlier work, that the methylaryl peroxides with the higher m. ps. are furoxans, MeC:N(:O).O.N:CAr, and those with the lower m. ps. are dioxdiazines, MeC:N.O.O.N:CAr. Because peroxides are relatively inactive, an extremely active reagent, *viz.*, MeMgI was used instead of PhMgBr, particularly since the latter also gave rise to secondary products. MeMgI was found to be much more active than EtMgI. With furoxans, MeMgI liberated 1 N atom as NH_3, leaving the other N atom as an ArCN compd., while with dioxdiazines both N atoms are detached and liberated as NH_3. The C atom of the furoxans which is united to Me and to the quinquevalent N atom combines with the Me of MeMgI with formation of AcMe, while with dioxdiazines both C atoms which are united to tervalent N atoms combine with the Me of MeMgI with formation of AcMe and a Me ketone. The fact that in furoxans the 2 N atoms behave differently, whereas in dioxdiazines they have an

identical behavior, agrees with the existence in furoxans of both ter- and quinquevalent N and in dioxdiazines of 2 tervalent N atoms, and shows that the $C_2N_2O_2$ group of furoxans has an asym. structure and that of dioxdiazines a sym. structure. Besides confirming the structures of furoxans and dioxdiazines shown above, *i. e.*, of the isomeric methylaryl peroxides, the expts. exclude the possibility that the peroxide with the lower m. p. can be the furoxan $MeC(:N.O.N(:O):CAr)$. The latter would behave like the other furazan $PhC(:N(:O).N:CAr)$, and yield with the Grignard reagent MeCN, which in numerous expts. could not be obtained, either as such or as its hydrolysis product AcOH, by the use of MeMgI, EtMgI or PhMgBr. The reaction between methylaryl peroxides and the Grignard reagent is difficult to interpret. If MeMgI attaches to an ethylenic double bond and thus brings about its rupture, the 2 isomeric peroxides have the same structure:

like that proposed by Green and Rowe for *o*-quinone dioxime peroxides (cf. *C. A.* **7**, 3119; **8**, 1412). This structure may, however, be that of the peroxides with the lower m. ps. which have been regarded as dioxdiazines $MeC(:N.O.O.N:CAr)$. With triphenylisoxazoline oxide, MeMgI adds to the $-C=N=O$ group (cf. Green and Rowe, *loc. cit.*) and then with water forms a compd in which the bond between C and N still exists. The same is true of the methylaryl peroxides with the high m. ps. (furoxans), but is not true of those with the lower m. ps. The latter do not, therefore, have this structure, *i. e.*, are not furoxans. *Exptl.*—Methylphenylfuroxan (5.5 g.), added cautiously to MeMgI in Et_2O (from 21 g. MeI, 250 g. Et_2O (distd. over Na) and 3.4 g. Mg), let stand after the reaction has subsided, the Et_2O evapd., ice-water added, steam-distd. and the distillate collected in dil. HCl, yields insol. PhCN. The latter is removed, and the mother liquor, boiled, yields AcMe in the distillate, while the dry residue is NH_4Cl. Under the same conditions methyl-*p*-bromophenylfuroxan yields *p* BrC_6H_4CN, AcMe and NH_3, and 4-methyl-5-*p*-bromophenyl 1,2,3,6-dioxdiazine (III) yields *p*-BrC_6H_4Ac, AcMe and NH_3. Crystd. from hot EtOH, III m. 92.3° (cf. 89.9° of earlier expts., Note L, *C. A.* **23**, 375). Similarly, methyl-*p*-methoxyphenylfuroxan (IV) and MeMgI yield *p*-$MeOC_6H_4CN$ (V), AcMe and NH_3. With EtMgI, IV reacts only with difficulty, with formation of V, MeCOEt and NH_3. 4-Methyl-5 *p*-methoxyphenyl-1,2,3,6-dioxdiazine (VI) and MeMgI form *p*-$MeOC_6H_4Ac$, AcMe and NH_3. With EtMgI, VI reacts only with difficulty, with formation of *p*-$MeOC_6H_4COEt$, MeCOEt and NH_3. Methyl[3,4-dihydroxyphenyl]furoxan methylene ether and MeMgI yield piperonylic nitrile, AcMe and NH_3. 4-Methyl-5-[3,4-dihydroxyphenyl]-1,2,3,6-dioxdiazine methylene ether and MeMgI yield 3,4-$CH_2O_2C_6H_3COMe$ (acetopiperone), AcMe and NH_3. **LXXII.** E. Durio and M. Bissi. *Ibid* 899–903.—In the oxidation of α-benzil dioxime (I) with alk. $K_4Fe(CN)_6$, Auwers and Meyer (cf. *Ber.* **21**, 806 (1888)) obtained the diphenyl peroxide $Ph(C_2N_2O_2)Ph$ (II) and a secondary product $C_{28}H_{20}O_2N_2$ (III). III has never been described since, yet its formation may be of importance in explaining the dehydrogenation of glyoximes to the so-called peroxides. The present paper shows that III is formed from the α- but not from the β-form of I, and describes the conditions which lead to a much higher yield than the extremely small yield by the procedure of Auwers and Meyers. Aq. 15% $K_4Fe(CN)_6$ (30 g.) added dropwise to I (10 g.) in 10% KOH (200 cc.), keeping ice-cold, the ppt. purified by boiling in EtOH and recrystg. the residue from glacial AcOH, yields 25–30% of the *compd.* $C_{28}H_{20}O_2N_2.2AcOH$; in air it loses slowly at room temp. and rapidly at 100° its AcOH of crystn., leaving III, which was proved to be *dioxotetraphenylpyrazine* $O:N:CPh.CPh:N(:O).CPh:CPh$. It is yellow, m. 322°, gives an intense red soln. in concd. H_2SO_4 (from which it is repptd. by water), is not altered by heating with HCl (d. 1.19) at 160–70° in a sealed tube. Traces of III are also formed by the oxidation of I with NaClO (cf. Note LXI, *C. A.* **24**, 3488). III (5 g.) in glacial AcOH and Zn dust (3 g.), heated several min. on a boiling water bath, filtered and the filtrate cooled, ppts. 3.5 g. of tetraphenylpyrazine (IV). After sepn. of IV, the mother liquor, made alk.

with NaOH and steam-distd., yields a small quantity of tetraphenylpiperazine. III and PCl_5 (equal parts), heated at 140–50°, yield a brown liquid which treated with water solidifies, and crystd. from glacial AcOH, yields *chlorotetraphenylpyrazine* (V), m. 212°, gives an intense red soln. in concd. H_2SO_4. This reaction is similar to that of furoxans under the same conditions (cf. Notes L and LVI, *C. A.* **23**, 375; **24**, 845), *i. e.*, III is first deoxygenated to IV, which then reacts with Cl with formation of V. The formation simultaneously of II and III from I proves that $K_4Fe(CN)_6$ acts on I in 2 distinct ways: (1) simple dehydrogenation which forms II, and (2) a more complex reaction which involves the elimination as HNO_2 of 2 H atoms and 2 NOH groups from 2 mols. of I, thus: $21 + 2O \longrightarrow III + 2HNO_2 + H_2O$. Since under the same conditions β- and α-benzil dioxime (VI and VII) form exclusively II, both NOH groups of VI and VII are dehydrogenated by oxidizing agents, whereas in I, 1 NOH group is dehydrogenated and the other is oxidized, *i. e.*, toward oxidizing agents the NOH groups of VI and VII behave the same and those of I differently. This behavior is analogous to that with Ni^{++} ions, where of the 3 benzil dioximes only I forms the complex Ni-$(C_{14}H_{11}O_2N_2)_2$ by substitution of 1 oximic H atom. The reduction of III by nascent H or PCl_5 to IV shows the presence of 2 extra-nuclear O atoms, confirms the formula

given and excludes the formula: O.O N CPh:CPh N.CPh:CPh. The reactions described in the present paper as well as those already known of glyoximes show that it is impossible to generalize, *e. g.*, α-*p*-tolil dioxime and anisil dioxime, which have many properties in common with I, yield on oxidation with $K_4Fe(CN)_6$ no trace of III.

C. C. DAVIS

Aminomalonic ester. Action of alkyl iodides and bromides on diethylsodioaminomalonate. R. LOCQUIN AND V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1377–80 (1930).—This is an introductory paper stating that $NH_2CNa(CO_2Et)_2$ reacts with alkyl iodides and bromides to give $RC(NH_2)(CO_2Et)_2$ in 50% yield. These substances are basic; they form cryst. compds. with KOCN and PhNCO. Previous work on $NH_2CH(CO_2Et)_2$ is reviewed.

I. M. LEVINE

Some alkylaminomalonic esters and their immediate derivatives. V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1381–5(1930).—By the action of 1 mol. of iso-C_4H_9I on 1 mol. of $NH_2CNa(CO_2Et)_2$ either in alc. or in iso-$C_5H_{11}OMe$ there was obtained 50% of *di-Et α aminoisobutylmalonate* (I), $C_4H_9C(CO_2Et)_2NH_2$, b_{14} 136°, n_D^{15} 1.4371, d_4^{15} 1.0109, M. R. 59.93 (calcd. 59.75). Treated with KCNO in AcOH I gave the corresponding *urea*, $C_4H_9C(CO_2Et)_2NHCONH_2$, m. 194°, and with PhCNO in Et_2O the *phenylurea*, $C_4H_9C(CO_2Et)_2NHCONHPh$, m. 128°, in 70% yield. On mixing 2 g. of I with 8 g. of water satd. with NH_3 at 0°, together with a few drops of EtOH and shaking vigorously, the *diamide*, $C_4H_9C(CONH_2)_2NH_2$, m. 153°, was formed on 24 hrs. standing. *Di-Et aminoallylmalonate* (II), $CH_2{:}CHCH_2C(CO_2Et)_2NH_2$, was prepd. from $CH_2{:}CHCH_2Br$ and $NH_2CNa(CO_2Et)_2$. II, b_{17} 134–5°, n_D^{23} 1.4442, d_4^{23} 1.039, M. R. 55.00 (calcd. 54.67); *urea*, m. 173.4°; *phenylurea*, m. 113°. Attempts to make *di-Et aminobenzylmalonate*, $PhCH_2C(CO_2Et)_2NH_2$, resulted in noncryst. oils, decompg. on heating, which gave with KCNO the *urea*, m. 234°, and with NH_4OH the *diamide*, m. 156°.

C. R. ADDINALL

Preparation of α-amino acids by hydrolysis of alkylaminomalonic esters. R. LOCQUIN AND V. CERCHEZ. *Bull. soc. chim.* [4], **47**, 1386–9(1930).—Alkylaminomalonic esters are hydrolyzed either by means of superheated steam at 150° in an autoclave or by refluxing with 10% HCl, to yield α-amino acids, CO_2 and ROH. The use of steam is preferable unless the resulting acid is insol. in H_2O. $NH_2CH_2CO_2H$ (I) (9.5 g. from 25 g. of $NH_2CH(CO_2Et)_2$), leucine, $PhCH_2CH(NH_2)CO_2H$ and $CH_2{:}CHCH_2CH(NH_2)CO_2H$ were obtained in this way. In the prepn. of I, the compd. I.*HCl*, m. 185°, was isolated.

I. M. LEVINE

The structure of some organic molecules. O. HASSEL AND E. NAESHAGEN. *Tids. Kemi Bergvesen* **10**, 126–7(1930); cf. *C. A.* **24**, 2346.—A preliminary notice concerning work on dipole moments, and discussing in this connection *meso*- and *dl*-forms. Racemic and active dichlorosuccinic acids gave almost identical values for the dipole moment (2.93×10^{-18}), the *meso*-form gave lower values (2.47×10^{-18}). β-Hexachlorocyclohexane (*trans*) has a center of symmetry, and dipole moment 0, while α-hexachlorocyclohexane (*cis*) has dipole moment 2.20×10^{-18} e.s.u.

G. R. YOHE

Preparation of bromoacetyl sugars and of acetoglucals. P. A. LEVENE AND ALBERT RAYMOND. *J. Biol. Chem.* **90**, 247–50(1931).—The prepn. of $BrCH_2CO$ derivs. of sugars can be greatly simplified by dissolving the reaction product resulting from the

action of HBr and Ac_2O on the sugar or of HBr in AcOH on the pentaacetate in C_7H_8, concg. the soln. at 40–50° under reduced pressure and renewing the C_7H_8 until all the excess reagents are removed. The $BrCH_2CO$ deriv. generally crystallizes directly in the distg. flask. The procedure in the prepn. of acetoglucals is also much simplified by the use of C_7H_8; it forms an azeotropic mixt. with the AcOH used as a solvent when treating the bromoacetylsugar with Zn dust. A. P. LOTHROP

Crystalline α- and β-methyl *d*-gulosides. HORACE S. ISBELL. *Proc. Nat. Acad. Sci.* **16**, 699–703(1930); cf. *C. A.* **25**, 1223.—Although a sirup of Me gulosides prepd. by condensation of the pure sugar with MeOH in the presence of 1% HCl could not be crystd. directly, the isomeric gulosides were sepd. by means of their cryst. addn. compds. with $CaCl_2$. By removal of $CaCl_2$ with $(CO_3Ag)_2$, the pure cryst. Me gulosides were prepd. and their parent $CaCl_2$ compds. reprepd. as a check on their original purity. The new compds. described are *α-Me d-guloside.*$CaCl_2.2H_2O$, $[\alpha]_D^{20}$ 67°, [M] 22,900; (*α-Me d-guloside*)$_2.CaCl_2.3H_2O$, $[\alpha]_D^{20}$ 83°, [M] 23,000; *α-Me d-guloside.*H_2O, decomps. 77°, $[\alpha]_D^{20}$ 109°, [M] 23,100; *β-Me d-guloside.*$CaCl_2.2H_2O$, m. 155°, moderately sol. in abs. alc., $[\alpha]_D^{20}$ —46°, [M] —15,640; (*β-Me d-guloside*)$_2.CaCl_2$, very slightly sol. in abs. alc., $[\alpha]_D^{20}$ —65°, [M] —16,200; *β-Me d-guloside*, m. 176° (uncor.) $[\alpha]_D^{20}$ —83°, [M] —16,100. The mol. rotations of all the α-forms are in good agreement with one another as are those of the three β-forms. The difference between the mol. rotations of the α- and the β-gulosides is 39,200 which compares favorably with the normal value 37,000. R. C. HOCKETT

β-Lactose. JOHN GORTON. *Svensk Farm. Tids.* **34**, 665–7(1930).—Lactose (100 g.) dissolved in 60 cc. H_2O over a free flame and set aside at 105° to crystallize gave 90% of β-lactose with $[\alpha]_D$ 39°, changing to 53.6° in 3 hrs. The $[\alpha]_D$ of the original lactose was 83.7°. The β-soln. when made alk. with NH_3 gave $[\alpha]_D$ 55.2° and the α, 52.7°. A. R. ROSE

Recent syntheses in the sugar group. AMÉ PICTET. *Atti III congresso naz. chim. pura applicata* **1930**, 36–41.—A brief review is given of the efforts to synthesize sugar with special emphasis on the methods involving condensation of the anhydrosugars and on the synthesis of sucrose. By heating starch with glycerol, 2 series of anhydrides (hexa-, tri- and diglucosans) are obtained which may be considered as polymers of glucosan. The 1st series of compds. is unaffected by I and the last member is an anhydride of maltose. The members of the other series are colored by I and the simplest is an anhydride of isomaltose. The members of the 1st series polymerize readily under the influence of light, giving substances colored by I. The triglucosan of the 2nd series in concd. aq. soln. protected from light, in time deposits a colloidal substance colored violet by I which is strikingly analogous to starch itself. Its acetate shows by f.-p. methods that it must be a dodecaglucosan, $(C_6H_{10}O_5)_{12}$. R. C. H.

Inulin. X. H. PRINGSHEIM, J. REILLY, W. G. HENSEL, W. BURMEISTER, P. P. DONOVAN AND MISS N. HAYES. *Ber.* **63B**, 2636–42(1930); cf. *C. A.* **24**, 3996.—Berner (*C. A.* **24**, 5730) has criticized the observation that inulin dissolves in liquid NH_3, fused $AcNH_2$ and (as its acetate) in AcOH with a mol. wt. corresponding to a difructose anhydride, and that by heat disaggregation and boiling of its acetate with $PhSO_3H$, as well as by soln. in $AcNH_2$, it is converted into an inulan of the same mol. wt. B ascribes the depressions observed to impurities, such as H_2O or alc. in the inulin and $AcNH_2$ in the inulan. The authors have shown by the CHI_3 reaction that the inulin they used was alc.-free and that the 10% of H_2O in the air-dried product is generally given off in 0.5 hr. at 78° *in vacuo* over P_2O_5. The inulan on distn. from alk. soln. gave no more color with Nessler reagent than did distd. H_2O. The mol.-wt. detns. were repeated independently at Berlin and Cork with due regard to these sources of error and the results confirmed by measurements in purified $HCONH_2$. Observing the precautions specified by Freudenberg (*C. A.* **24**, 1846), values corresponding to 2 × $C_6H_{10}O_5$ were in most cases obtained for inulin in both $HCONH_2$ and $AcNH_2$, although double this value was obtained in 2 cases; whether this was due to previous treatment in the prepn. and purification or to the fact that natural inulin, as believed by Schlubach, is not a homogeneous substance remains to be tested. The inulan in H_2O soln., when sufficiently dil., again gave values corresponding to the 2 × C_6-stage. Drying has some influence on its original H_2O-soly. but even after especially vigorous drying at 110° it showed, after soln. in hot H_2O, a mol. wt. (387) not very much higher than 2 × 162. Schlubach and Elsner and Jackson and Goergen have observed that a small amt. of glucose is formed along with the fructose in the acid hydrolysis of inulin. The present authors also observed, by differential titration according to Bertrand on the one hand and Willstätter-Schudel on the other, an aldose content higher than could be accounted

for by exptl. error (Cu:I, 100:7.0–9.4). Expts. on pure fructose under the conditions of the Willstätter titration showed that it is attacked to the extent of about 2.8%, the aldose content in the acid hydrolyzate of inulin thus being reduced to about 5%. Taking this titration error into account, no glucose could be found in the inulinase hydrolyzate, thus confirming Bourquelot and Bridel. This, however, does not prove that inulin contains no glucose, for the max. of hexose obtained by the ferment hydrolysis, as detd. with Fehling soln., was only 90% even after weeks and months.

Methylated tri- and tetra-saccharides from cellulose and starch. KARL FREUDENBERG AND KARL FRIEDRICH. *Naturwissenschaften* **18**, 1114(1930).—Recently cryst. decamethyl-β-methylcellotrioside, $b_{0.08}$ 216–20°, was prepd. by acetolysis and methylation of cellulose (*C. A.* **25**, 85). The cellobiose deriv., b. 60° lower, is also obtained by the same distn. The methyltetrose $b_{0.1}$ 265–75° and is also obtained in crystals with all the properties of a tridecamethyl-β-methylcellotetroside. Both compds. crystallize easily in water or petr. ether even when the MeO content is 1–2% too low. Repeated methylation of the cryst. prepn. gives an analytically correct and uniform product with the expected mol. wt. in camphor. The methylated trisaccharide, m. 118°, has α_{578}^{18} —17° in water, the methylated tetrasaccharide, m. 139°, α_{578}^{18} —14.6°. From the products of acetylated starch corresponding, but noncrystallizable, fractions were obtained after methylation: a methylated trisaccharide, α_{578}^{19} 133° (water), mol. wt. 613 (calcd. 658), and a methylated tetrasaccharide, α_{578}^{18} 140° (water), mol. wt. 812 (calcd. 862). These products of starch are the α-glucosidic analogs of the methylated oligosaccharides from cellulose, the former having MeO in α- as well as β-positions. From demolition kinetics it was deduced (cf. preceding abstr.) that starch as well as cellulose has a chain structure. The present data are addl. evidence. The same structure is required for inulin contrary to the opinions of Pringsheim (following abstr.), Schlubach (*C. A.* **25**, 245) and Staudinger (*C. A.* **25**, 280). B. J. C. v. D. H.

Chemistry of starch. XXIV. New polyamyloses. I. HANS PRINGSHEIM, ALFRED WIENER AND ALEXANDER WEIDINGER. *Ber.* **63B**, 2628–36(1930); cf. *C. A.* **24**, 3996.—When $AcNH_2$, which, it had been found, can be used as a f.-p. solvent for complex saccharides such as inulin and glycogen, was tried with α-tetraamylose (I), it gave values for the mol. wt. corresponding, not to a tetra- or diamylose, but to a hexose anhydride (162). In view of the possible effect of the high temp. of molten $AcNH_2$ (above 80°) on the labile polyamylose, the mol.-wt. detns. were repeated in $HCONH_2$ but with the same results. At first higher values (never below and often above 2 × 162) were obtained, but this was traced to impurities in the $HCONH_2$ (Schering-Kahlbaum, m. —5° to —7°, with about 1% HCO_2H). When this had been purified until it was acid-free and m. 1.8–2°, it always gave for I a mol. wt. corresponding to a glucose anhydride. Pptn. of the $HCONH_2$ soln. with alc. gave 80% of a cryst. substance (II) sepg. from hot aq. alc. with 1 mol. H_2O in column-shaped prisms having, when dried, the compn. and mol. wt. (in H_2O) of a glucose anhydride and giving with I-KI the long green needles with metallic luster characteristic of α-amyloses. II is therefore designated as *α-amylosan*. The mother liquor from the II, freed of alc. and $HCONH_2$ *in vacuo* and pptd. with EtOH-Et_2O, gave an amorphous product (III), sepg. from dil. alc. in rhombic tables with 1 mol. H_2O, which could best be differentiated from II by means of I-KI which gave brown-red prismatic columns like β-polyamyloses. III, which is called *β-amylosan*, also has the compn. $C_6H_{10}O_5$ but gives a mol. wt. of 2 × 162 in both H_2O and $HCONH_2$. β-Hexaamylose (IV) showed a mol. wt. of 2 × 162 in both $AcNH_2$ and $HCONH_2$ and when pptd. from $HCONH_2$ with EtOH-Et_2O yielded 90% of III. Like the polyamyloses II and III form with org. solvents difficultly H_2O-sol. addn. products by means of which they can readily be isolated from aq. solns. The II and III were further characterized by means of their acetates. In AcOH the acetate of III was dispersed nearly to the C_6-stage in 24 hrs. On heating, the rotations of aq. solns. of II and III change to a final const. value (II, from 150° to 128°; III, from 179° to 150°) and recrystn. of the resulting products from dil. alc. gives well-crystd. substances, α- (V) and *β-isoamylosan* (VI). Neither V and VI nor their I and Br addn. products differ visibly in cryst. form from II and III and their corresponding derivs. In $HCONH_2$ V and VI give the expected mol. wts. and after pptn. their rotations are found unchanged. In H_2O, however, they show a pronounced tendency to aggregate, gradually passing after several days at room temp. into a colloid-dispersed state. II, heated 6 hrs. on the H_2O bath in $HCONH_2$, changed to a substance (VII) sepg. from aq. alc. in 6-sided tables and yielding an especially characteristic I addn. product in black-green prisms. I, II, III and IV in aq. C_5H_5N (7:3) all showed

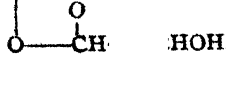
the same specific rotation (133°). **II**, $[\alpha]_D^{20}$ 144.8–9° (H_2O). **III**, $[\alpha]_D^{20}$ 173–81° (H_2O). *α-Triacetylamylosan*, $[\alpha]_D^{20}$ 120–4° ($CHCl_3$), mol. wt. 256–307 (AcOH). *β-Triacetylamylosan*, $[\alpha]_D^{20}$ 129–32.5° ($CHCl_3$), mol. wt. 332 (AcOH). **V**, $[\alpha]_D^{20}$ 127–33° (H_2O). **VI**, $[\alpha]_D^{20}$ 150–2° (H_2O), 148.5° (H_2O-EtOH, 1:1). C. A. R.

Lignin and cellulose. XIV. The hydrolysis of polysaccharides. KARL FREUDENBERG, WERNER KUHN, WALTER DÜRR, FRITZ BOLZ AND GUSTAV STEINBRUNN. *Ber.* **63B**, 1510–30(1930); cf. *C. A.* **24**, 1846.—In the series of researches relating to the kinetics of the degradation of polysaccharides, the measurements on disaccharides and other sugar derivs. formed a communication preliminary to those on cellulose and starch (*C. A.* **23**, 106). Starch is now investigated under the conditions used with cellobiose and maltose. For cellulose 50% H_2SO_4 was used; soln. and hydrolysis followed just as with starch and cellodextrin (the biosan of Hess). The detn. of the aldehyde groups freed was made with 0.1 *N* I. The Cu method does not work because cellobiose reduces more Cu than 0.5 glucose; the 2nd glucose group is attacked after destruction of the 1st. The velocity const. for the hydrolysis of cellobiose by 50% H_2SO_4 at 18° was found to be 1.07×10^{-4} (t in min.) by means of well-agreeing I titrations and polarimetric observations. With cellulose the degree of hydrolysis as detd polarimetrically is in advance of the degree as detd. by titration with I. The object was to find which of the possible courses of reaction (see last reference, hypotheses II, III and V) best suits the data as obtained by the latter method. Of the consts assumed, k_2 is known from the velocity of hydrolysis of cellobiose. k_1 is the initial velocity const. of the reaction in all 3 cases. It is found either by extrapolation to an infinitely short time from the mean velocity const. P_0, or is detd. from k_2 and any one value of P (P_{50} was chosen, *i. e.*, P for $\alpha = 0.50$) with the aid of the tables calcd from one of the 3 fundamental formulas expressing the relation between k_2, k_1 and k_2/P_{50}. The degree of agreement between the entire courses of the empirical and theoretical curves shows the applicability of the fundamental relation on which the formula used is based. Hypothesis II (k_2 only for cellobiose different from k_1) is eliminated while hypothesis III (k_2 for disaccharide and trisaccharide) gives good and hypothesis V (biosan conception) fairly good agreement. Formula III is the better expression, especially for the final stage of the reaction. The fission of cellulose at 30° gives entirely analogous results. *Hydrolysis of biosan acetate* (Hess and Friese, *C. A.* **21**, 174). Biosan acetate was crystd. from $CHCl_3$-MeOH, extd. with the latter and the Ac group removed according to Fischer and Zemplen; the H_2O-insol. portions of the free dextrin were used. $[\alpha]_{578}$ in 2 *N* NaOH −9.95°. Fission at 18° and 30°. k_1 is as large as in the case of cellulose and here also hypothesis III is better suited than V to explain the kinetics. *Hydrolysis of starch.*—k_2 (maltose) at 18° 1.60×10^{-4}. Kahlbaum's sol. starch, $[\alpha]_{578}$ in formamide (0.5%) 195°. k_1 by extrapolation = 1.07×10^{-4}, by hypothesis III, found 1.19×10^{-4}. The curve constructed according to this agrees well with that found empirically. Hypothesis II is eliminated here, but not the biosan assumption (V). Similar facts hold good for the hydrolysis at 30°. *Hydrolysis consts. of disaccharides.* Solns were 0.1 *N* in 2 *N* H_2SO_4 at 70° (t in min.). gentiobiose 3.06; levoglucosan 6.9, trimethyl levoglucosan 1.0; Me mannoside ($[\alpha]_{578}$ 79° in H_2O) 1.8×10^{-4} in good agreement with similar measurements of Moelwyn-Hughes (*C. A.* **22**, 1888; **23**, 5089, 5393, **24**, 2154). The consts. given by von Meyer, Hopff and Mark (*C. A.* **23**, 4451) for the inversion of maltose are not in agreement. *Optical Rotations.*—In connection with the polarimetric detn of the degree of degradation, it is to be borne in mind that the rotatory power, unlike the I value, does not lie around the half-point between glucose and cellulose (see above). An effort is made to reach a better approximation by assuming the rotations of the tri- and tetrasaccharides to correspond to their position between the disaccharide and polysaccharide. The values calcd. from assumption III are in better accord with the actual detns. than those from V but a close agreement between the values so calcd. and the α-values found titrimetrically is not obtainable. The former (III) remain somewhat behind the detd. values which indicates that the rotations of the tri- and tetrasaccharides are somewhat higher than those indicated by the new assumption. Thus the deviations may be explained without difficulty. In contrast, the biosan theory requires exact applicability of the derived formulas. Large and const. deviations indicate more than mere exptl. errors. From the dependence of the velocity consts. of hydrolysis upon temp. the heats of activation are derived for the fission of the compds. and the thermal proportionality factors. The heats of activation of starch and maltose are not significantly different from one another while those of cellulose and cellobiose are well distinguished, the former being smaller. That, nevertheless, the velocity const. for cellulose is smaller is to be ascribed to the much

smaller thermal proportionality factor. Similar, but less pronounced, are the relations with starch and maltose. The kinetic considerations exclude a 2nd type of linking along with the cellobiose linking. Since fully methylated cellulose decomps. only into 2,3,6-trimethylglucose, the only alternative lies between the α- and β-linkings on C atom 4. A disaccharide more difficultly hydrolyzed than cellobiose or one equally easily split, along with cellobiose, would be comprehensible but one more easily hydrolyzed (like maltose) would make itself noticeable through a more rapid course of reaction. With cellodextrin, the extrapolated initial I consumption indicates a chain length of 30 to 40 glucose residues (mol. wt. around 5000 to 7000). The authors explain the deviation from the lower value of Bergmann and Machemer (*C. A.* **24**, 2877) by the fact that in the free dextrin used, the lower water-sol. parts were removed, and these must have been present in the biosan acetate used by Bergmann. With cellulose, a parallel situation is found, giving a chain-length of 50 glucoses. Cellodextrin is close to cellulose also as indicated by its lower rotation. The chain of cellulose is assumed to be actually longer since small admixts. of lower carbohydrates can raise the I value. The very different properties of cellodextrin from those of cellulose (soly., viscosity) are to be attributed to the proportionate length of chain, the former having been partially shortened, the entirely undegraded fragments especially being absent. From the I requirement, starch indicates a chain-length of 25-30 glucose residues. The sol. starch used was perhaps partly degraded already. A strict literal application of assumption III forces us to make a fundamental distinction between the di- and trisaccharides and the tetrasaccharides. If the middle linking within a long chain always reacts according to k_1, the outer linking according to k_2, then formula III would be a 1st but only a poor approximation. Necessary modifications would have to be made if higher fission consts. of intermediate values between k_2 and k_1 were to be ascribed to the outer bindings. It would be conceivable that the glucoses should be split off more rapidly at 1 or both ends (perhaps according to k_2) while the rest hydrolyzed more or less according to k_1. The detn. thus far of the max. yield of cellobiose depended upon the assumption of similar stability of the linkings throughout the chain. If this proves incorrect, then the cellobiose resulting during all stages of degradation would have to remain under 67%, which agrees with a series of new results (50-60%). With starch, it is more difficult to decide regarding the small difference between the initial and final velocities, but the complete analogy between the degradation and the optical changes makes a chain structure seem likely here also. The high yields of acetobromomaltose which Karrer (*C. A.* **16**, 63) obtained by the AcBr degradation of starch are explained by the fact that that substance is attacked more slowly by AcBr than the chain compds. The diastatic degradation is explained by a similar linking of all the glucose residues of the starch chain, but with a series of accessory assumptions confirmed by kinetic observations. A chain formula is also required for inulin. The newly detd. facts are reconcilable with the chain formulas and a uniform interpretation is possible only with this conception. R. C. HOCKETT

Lignin and cellulose. XV. Lignin and nitrogen peroxide. KARL FREUDENBERG AND WALTER DURR. *Ber.* **63B**, 2713-20(1930); cf. preceding abstr.; Schaarschmidt, *Z. angew. Chem.* **42**, 618(1929).—After it had been found that the reaction of Br on lignin consists in substitution and not addn., it remained to be detd. whether lignin behaves toward nitrating agents also as an aromatic substance. The action of HNO_3 on lignin is not clear cut; the reaction does not stop at a definite stage but comes to a standstill only when products of deep-seated degradation, which are no longer characteristic, have been formed. Better results were to be expected of NO_2, which with aromatic compds. gives substitution derivs., preceded by addn. of 2 mols. NO_2 at the double bond, with subsequent elimination of HNO_2. In preliminary expts. in a N-filled app. in ice, connected with a manometer to record changes in pressure, the pressure, within a few min. after bringing the NO_2 (mixt. of NO_2 and N_2O_4) and lignin together, fell far lower than in blank expts. with NO_2 alone and remained const. for a while, but after about 0.5 hr. it rose slowly for 3 days, owing to the evolution of NO. Attempts to follow the reaction quantitatively failed because of the extraordinary adsorbing power of the lignin and the complex equil. between NO, NO_2, N_2O_4, HNO_2, HNO_3 and H_2O. There is no doubt that the gradual increase in pressure is due to a secondary reaction, evidently an oxidation process, and that only the first rapid phase (decrease in pressure) marks the course of the reaction sought. This is even more evident when methyllignin is used instead of lignin. Etherification seems to block the point of attack for the oxidation reaction; with methyllignin the pressure falls to a min. within a few min. and then remains unchanged for days. The expts. were then conducted under conditions which permitted of converting the nitrous gases in the reaction vessel after

the nitration into a mixt. of nitrite and nitrate which was then analyzed by the method of Meisenheimer and Hein. The gas remaining after absorption of the nitrous gases in aq. $NaHCO_3$ was pure NO; no org. oxidation products (especially no $(CO_2H)_2$) were found in the $NaHCO_3$ soln. and no CO_2 was formed in the nitration. The only cleavage product found was MeOH. The amounts of NO_2 used, of NO, HNO_2 and HNO_3 formed and of N in the nitrated lignin or methyllignin correspond best to a nitration process: —O.C_6H_3(OMe).C.C.C— + $2NO_2$ = —O.C_6H_2(OMe)(NO_2).C.C.C— (I) + HNO_2. Definite proof that double bonds do not come into play at all or only to a small extent is afforded by the fact that the nitrolignin and nitromethyllignin can still be brominated (nitrolignin takes up about 0.7 atom Br per atom of N) and that bromomethyllignin can be nitrated. The cleavage of MeOH (20–33% of that originally present in the lignin) had already been observed in the bromination; as it occurs to the same extent whether lignin or methyllignin is used, there is no doubt that it is the original MeO group in lignin that is split off. This cleavage of MeOH is explained on the basis of Wieland's theory that the substitution of NO_2 is preceded by an addn. Assuming, arbitrarily, that the NO_2 group enters the *p*-position to the MeO group it would be expected that the first product would be a di-NO_2 compd —O.C<CH——CH(NO_2)>C.C.C.C— / C(OMe)(NO_2).CH which for the most part would change normally, by loss of HNO_2, into I, but, to a small extent, the MeO group, reacting with the adjacent NO_2 group as if it were —O.NO, would split off as MeONO and the resulting quinol deriv. would change into the nitrophenol —O.C_6H_2(OH)(NO_2).C.C.C—. Dimethyldehydrovanillin, [5,2,3-OHC(MeO)$_2$$C_6H_2$]$_2$, in solid amorphous form, treated with NO_2 like lignin, is similarly nitrated, with elimination of 2.5 mols. MeOH. Veratrumic acid, both in solid form and in $PhNO_2$, is nitrated but splits off only traces of MeOH. Veratroylcellulose (18.6% MeO) takes up 12.5% NO_2 but almost without loss of MeOH. F. and D. feel that the results of bromination and nitration show that lignin is predominantly an aromatic substance and confirm the the formula —O.C_6H_3(OMe).C.C.C(—O.C_6H_3(OMe).C.C.C—)$_x$ —O.C_6H_3(OMe).C.C.C— previously suggested. These new results show again that all the reactive groups are free since the lignin reacts with the completeness of a permutoid. A further example (the mercuration of lignin) is to be described shortly. Lignin differs from a directed permutoid like siloxene in that the structural elements apparently extend in 3 dimensions entirely without any order, resulting in an extraordinary development of surface, as indicated by the strong adsorbing power. A further peculiarity is that the structural elements are apparently not all entirely identical, although derived from a basic form closely related to coniferyl alc. or guaiacylglycerol; presumably there are differences in the aliphatic chains, and furthermore a small part of the aromatic nuclei are present in the form of the piperonyl residue. The size of the particles formed by condensation also seems to vary widely in one and the same prepn. As a result, the reactions of lignin are by far not nearly so homogeneous as those of permutoids of regular structure. C. A. R.

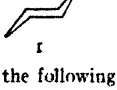


Constitution of cellulose xanthate. III. Th. Lieser. *Ann.* **483**, 132–43(1930); cf. *C. A.* **23**, 3672.—Treatment of methylcellulose with a mixt. of AcOH and Ac_2O contg. H_2SO_4 at 25–30° for 7–20 days gives about 50% of cellobiose octaacetate, indicating that some of the glucose anhydride units in the original product are not methylated. No methylcellobiose acetate could be detected; it is probably decompd. during acetolysis. C. J. West

Action of mercury salts on acetohalogenosugars. IV. Direct preparation of alkyl biosides of the α-series. Géza Zemplén and Arpád Gerecs. *Ber.* **63B**, 2720–4 (1930); cf. *C. A.* **24**, 5730.—It had been found that heptaacetyl-α-alkylcellobiosides can be obtained in faultlessly pure condition by the action of $Hg(OAc)_2$ on acetobromocellobiose (I) in the presence of the appropriate alc., but the results were not always reproducible, especially with the Et compd., and the quality of the product varied

widely with the amt. of the alc. used. Systematic expts. were therefore carried out in which only the quantity of abs. alc. used was varied: the mixt. of I (10 g.), $Hg(OAc)_2$ (2 g.) and EtOH was boiled 2 hrs. in 60 cc. C_6H_6, the cooled reaction mixt. washed 4 times with H_2O, the C_6H_6 soln. dried with $CaCl_2$, evapd. *in vacuo*, then twice with EtOH and the residue dissolved in 50 cc. hot alc. and allowed to stand 6 hrs. at room temp. The product, recrystd. once more from alc., was then tested for reducing power, rotation in $CHCl_3$ and m. p. The results showed that whether the product isolated shall be the α- or the β-form can be controlled by the proper choice of the quantity of alc. used. The α-Et deriv. can be obtained with certainty with an excess in the neighborhood of 100% of EtOH; even with a 200% excess the product is still a quite pure α-deriv. but the yield is no longer satisfactory (with a 100% excess the purity and the yield are as good as in the isomerization of the β-compd. with $TiCl_4$ and the procedure is materially simpler). When the excess of alc. exceeds 300%, however, the reducing power of the product again increases and between a 300 and 400% excess of alc. there is a sharp transition in favor of the β-form. With 10 g. I, a difference of 0.74 g. in the quantity of EtOH used sufficed to change the rotation of the product from 50.86° to —18.26°. With iso-PrOH the α-deriv. can be obtained more easily than with EtOH, a 40–200% excess of the iso-PrOH giving an optically very pure product in good yields; the transition in favor of the β-form with a further increase in the quantity of alc., however, is even more marked than with EtOH. With Pr, Bu, iso-Bu, *sec*-Bu, *sec*-Am, hexyl and $PhCH_2CH_2$ alcs., a 100% excess of the alc. often gave the α-deriv. of highest rotation. To obtain the β-forms, a large excess of the alc. must be used. With the lower alcs., it is advantageous to use the alc. itself as the reaction medium. The β-derivs. can often also be obtained readily with $Hg(CN)_2$ instead of $Hg(OAc)_2$ but attempts to prep. the α-compds. in this way met with but little success. The highest $[\alpha]_D$ in $CHCl_3$ observed for the α- and β-forms, resp., of the *heptaacetylalkylcellobiosides* were: *Me* ——, —25.0°; *Et* 57.23°, ——; *Pr* 58 79°, ; *iso-Pr* 59.29°, —22.7°; *Bu* (m. 172°) 52.40°, —24.60°; *iso-Bu* (m. 174°) 45.51°, 23.04°; *sec-Bu* (m. 193°) 55.76°, —23.20°; *sec-Am* (m. 193°) 52.23, ——; *hexyl* (m. 182°) 53.42°, —24.37°; *β-phenylethyl* (m. 207°) 54.16°, —25.28°. C. A. R.

New substances formed by molds. NADINE WIJKMAN. *Ann.* **485**, 61–73(1931).—The action of *Penicillium glaucum* on sucrose in new glass vessels gives a mixt. of *glauconic acids 1* (I) and *2* (II), sepd. by crystn. from EtOH. I, $C_{18}H_{28}O_{17}$, m. 202°, is optically inactive, contains no MeO group, gives no color with $FeCl_3$ and from its behavior on titration appears to contain 1 or more lactone groups. I is not esterified with MeOH-HCl; with CH_2N_2 N is evolved, giving a product boiling at 210° in high vacuum; it could not be crystd. *Ac deriv.*, m. 175°; *Bz deriv.*, m 170°; *NO_2 deriv.*, m. 159°. Reduction of I with Zn and AcOH gives the *compd.* $C_{18}H_{32}O_{17}$, m. 237°. Distn. of I in N at 215° gives the unsatd. *ketone* (III), $C_7H_{12}O$, b_{146} 120°, which absorbs 2 Br and 2 H (*dinitrophenylhydrazone*, red, m. 173°; *semicarbazone*, m. 183°) and the *compd.*, $C_{11}H_8O_6$, m. 171°. Oxidation of III gives the *compd.* $C_3H_6O_2$, analyzed as the *Ag salt*. II, $C_{18}H_{30}O_{18}$, m. 186°, distd. undecompd. in a high vacuum and titrates as a 4-basic acid. I is probably a HO deriv. of II. C. J. WEST



Xylan. J. REILLY, P. P. DONOVAN AND MISS K. BURNS. *Proc. Roy. Irish Acad.* **39B**, 505–14(1930); cf. *C. A.* **23**, 337; **24**, 831, 3996.—The work on the effect of soln. of polysaccharides in $AcNH_2$ (I) and $HCONH_2$ (II) was extended to the pentosans. Abs. EtOH pptd. from a 0.5% soln. of xylan (III) in I a substance which was sol. in cold H_2O while moist but which on drying became horny and insol. in cold H_2O but sol. on short heating to 50°. This ppt. (called *xylanan*) (IV) possessed the same rotatory power as the original III, ($[\alpha]_D^{20}$ —111.1° to —113°), and analysis showed its empirical formula to be $(C_5H_8O_4)_n$. F.-p. detns. of the mol. wt. on III in I at 0.451% concn. gave the values 146 and 147; at 0.95%, 195 and at 1.1%, 231. These values point definitely to depolymerization with formation of the mols. $C_5H_8O_4$ and $(C_5H_8O_4)_2$. Mol.-wt. detns. in H_2O on dried IV from I gave the values 340, 388 and 485 at 0.73% concn. and 353, 412 and 480 at 0.93% concn. Similar detns. on IV from II gave 344, 383 and 453 at 0.926% concn. and 369, 415 and 513 at 1.049% concn. The values indicate the formula $(C_5H_8O_4)_3$ for IV with increasing assocn. on standing. I and II may act as imino acids to produce depolymerization or it may be that the fundamental units of III are assocd. through their residual valences and that these valences are altered when the III is dissolved in I or II. If the units of III are linked through auxiliary valences, the structure of the unit should be:

Resolution of some ester acids of the γ-truxillic acids into the optical components. FRIEDRICH SCHENCK. *Ber.* **63B**, 2706–12(1930).—It has thus far not been possible to resolve the mono esters of α-truxillic and β-truxinic acids into their optical components. Stoermer and Fretwurst showed, however, that the γ-truxillamidic acids are readily resolved with morphine. The present work was undertaken to det. whether the mono-esters of γ-truxillic acid are also resolvable. To obtain the active monoesters, the following active amidic acids, some of which had already been described by Fretwurst, were prepd.: *d*-Me (+)γ-truxill-*l*-amidate (I), *l-Me* (−)*d-amidate* (II), *l-Et* (−)*d-amidate* (III), *l-Pr* (−)*d-amidate* (IV), *d-Bu* (+)*l-amidate* (V). These were converted with N_2O_3 in AcOH into the following truxillic monoesters: *Me* (+)*d-γ-truxillate* (VI), *Me* (−)*l-truxillate* (VII), *Et* (−)*l-truxillate* (VIII), *Pr* (−)*l-truxillate* (IX), *Bu* (+)*d-truxillate* (X). As standards of reference were taken Fretwurst's active amidic acids. The *l*-form corresponds to the negative, the *d*-form to the positive rotation. When such an acid (*e. g.*, the *d*-amidic acid) is esterified it becomes, as regards the ester group, the *l*-form, *i. e.*, the *d*-amidic *l*-ester, for if the amide group should be sapond. and the remaining ester group replaced by NH_2, the *l*-amidic acid should result. Attempts to effect such a replacement have hitherto failed. As with the amidic acids, the *d*-forms of the monoesters have a pos., the *l*-forms a neg. rotation. The direction of the rotation of VII and VIII, which was not detd. directly, was deduced from the m. ps with the active compds obtained by resolution (see below). The inversion of the rotation on esterification of the amidic acids noted by Fretwurst was again observed, as was also the increase in the magnitude of the rotation. To obtain the *dl*-monoesters, γ-truxillic anhydride was boiled with an excess of alc. and about 0.5 mol. Na_2CO_3, and the resolution was effected by bringing together hot satd. alc. solns. of 1 mol. each of the monoester and morphine, the salts of the (−)*l-Me*, (−)*l-Et*, (−)*l-Bu* and (+)*l Pr esters* crystg. out while the antipodes remained in soln. and sepd. only on cautious evapn. With brucine, the antipodes formed the difficultly sol. salts (the Bu ester could not be resolved with this alkaloid). The magnitude of the rotation increases with increasing mol. wt. of the alc., and the m. ps. of the *d* esters decrease while those of the active esters increase with increasing mol. wt., with the exception of the Me ester. *dl-Monoesters: Me*, m. 183.5–4°; *Et*, m. 173–4.5°; *Pr*, m. 170–1°, does not depress the m. p. of the Et ester; *Bu*, m. 142–3°, seps. from H_2O as a *hydrate*, m. 62–3°. II, m. 153–4°. III, m. 153–4. IV, m. 159–60°, $[\alpha]_D^{20}$ −17.7° (all rotations measured in Me_2CO). V, m. 141.5–3°, $[\alpha]_D^{20}$ 18.33°. *Di Bu truxillate* from the acid with BuOH-H_2SO_4, m. 85–6°. VII, from II with N_2O_3 or from the *d* ester with morphine, m. 145.5–7°, a mixt. with VI m. 178–83°. VI, from I and N_2O_3 or from the *dl*-ester with brucine, m. 145.5–7°, $[\alpha]_D^{18}$ 6.48° (prepd. by 1st method) $[\alpha]_D^{20}$ 4.37° (prepd. by 2nd method). VIII, m. 142.5–3°, $[\alpha]_D^{18}$ −16.48°, m. 67–8° when mixed with the (+)*d ester* (from the *dl*-ester with morphine), m. 142.5–3°, $[\alpha]_D^{20}$ 19.14°. IX, m. 148–9°, $[\alpha]_D^{21}$ −21.35° when prepd. from IV with N_2O_3, $[\alpha]_D^{19.5}$ −22.1° when prepd. from the *dl*-ester with brucine, m. 168–70° with the (+)*dl-ester* (from the *dl*-ester with morphine), m. 148–9°, *Bu* (−)*l-γ-truxillate*, from the *dl*-ester with morphine, m. 151–2°, $[\alpha]_D^{18.5}$ −25.70°. X, m. 151–2°, $[\alpha]_D^{21}$ 26.14°. C. A. R.

The structure of the cyclohexane molecule. O. HASSEL AND H. KRINGSTAD. *Tids. Kemi Bergvesen* **10**, 128–30(1930).—Since satd. hydrocarbons have practically 0 dipole moment, a distinction between the possibilities I and II for cyclohexane by dipole measurement is not possible. X ray investigation, with a Debye camera, C_6H_{12} frozen with solid CO_2 acetone mixt., and Fe radiation gave the following data. Lattice, cubic; a = 8.41 ± 0.02 A. U.; 4 mols. per unit cell; d 0.933. The space group is probably T_h^2 or O_h^4. These results indicate the form of the cyclohexane mol. to be I.

Two syntheses of heptamethylenimine. ADOLF MÜLLER AND PAUL BLEIBR. *Monatsh.* **56**, 391–406(1930). Reduction of suberone isoxime (α-ketoheptamethylenimine) with Na and EtOH gives 1.5% slightly impure heptamethylenimine (I), b. 162–4°, d_4^{17} 0.869, n_D^{17} 1.5262 (*chloroaurate*, sinters 173°, m. 188°; *picrate*, m. 147–8°; *N*-Bz deriv., b_{13} 196–7°). Oxidation of the *N*-Bz deriv. with $KMnO_4$ at 65° gives 41.3% of ζ-benzamidoheptoic acid, dimorphous, m. 86° and 90°; this also results by benzoylating the amino acid, obtained by heating suberone isoxime with 20% HCl at 150°. Hydrolysis of the reaction product of α,η-dibromoheptane and *p*-$MeC_6H_4SO_2NH_2$ with EtOH-KOH by HCl at 160° yields 0.8% of slightly impure I and α,η-diamino

heptane. Improved methods are given for the prepn. of suberic acid, suberone and its isoxime. C. J. West

Migration of amino groups from one to three in arylamine derivatives of diarylarylethinylcarbinols. Constitution of resulting products. Joseph Robin. *Compt. rend.* **191**, 790–2(1930); cf. *C. A.* **24**, 78.—$PhNH_2$ with *diphenylphenylethinylcarbinyl chloride* ($Ph_2CClC:CPh$) (I) gives a yellow product, *$Ph_2C:CHCPh:NPh$* (II), m. 199–200° A colorless intermediate product, *$C_{27}H_{21}N$* (III), m. 87–8°, has been isolated. III isomerizes easily into II by the action of heat in the presence of $PhNH_2.HCl$, but not in the presence of $PhNH_2$. II has not been converted into III. III is more basic than II, forming an isolable *HCl salt*. With MeOH in dil. H_2SO_4, II gives *β-phenylbenzalacetophenone*, while III gives *diphenylethinylcarbinyl Me ether*. III is probably $Ph_2C(NHPh)C:CPh$. These relationships hold in a variety of similar cases where an arylamine with a diarylarylethinylcarbinyl chloride gives 2 isomers, the unstable product (*a*) of the type of formula II being white, and the stable product (*b*) of the type of formula III being yellow. I with *o-toluidine* gives (*a*), m. 139–40°, and (*b*), m. 192–3°; with *m-toluidine* (*a*), m. 117–8° (*b*), m. 139–40°; with *p-toluidine* (*a*), m. 115–6° (*b*), m. 174–5°; with *o-anisidine* (*a*), m. 140–1° (*b*) not crystd; with *p-anisidine* (*a*) not crystd., (*b*) m. 148–9°. *Diphenyl-p-tolylethinylcarbinyl chloride* with $PhNH_2$ gave (*a*), m. 118–9°, (*b*), m. 162–3°. *Diphenyl-β-naphthylethinylcarbinyl chloride* with $PhNH_2$ gave (*a*), m. 140–7°, (*b*), m. 149–50°. *Diphenyl-p-bromophenylethinylcarbinyl chloride* with $PhNH_2$ gave (*a*), m. 151–2°, (*b*), m. 138–9° T. H. Rider

The action of hexahalogenated benzenes on Grignards. J. F. Durand and Lai-Wai Hsun. *Compt. rend.* **191**, 1460–3(1930).—C_6Cl_6 reacts with neither MeMgI nor PhMgBr. C_6Br_6 or C_6I_6 with MeMgI gives C_6Me_6, m. 157.8°, and with PhMgBr C_6Ph_6, m. 266°, b. 418–20°. V. F. Harrington

Chlorination of *o-* and *p*-nitrotoluene. 3,4,6-Trichloro-2-nitrotoluene and 2,6-dichloro-4-nitrotoluene. Leopold F. Levy and Henry Stephen. *J. Chem. Soc.* **1931**, 76–9.—*o*-$O_2NC_6H_4Me$ (27.4 g.) and 5 g. $SbCl_5$, satd. with Cl, give 5 g. of the *3,4,6-Cl_3 deriv.*, pale yellow, m. 93–4°; further nitration gives the 2,5-di-NO_2 deriv., m. 220.5° (cor.). Reduction with $SnCl_2$ and HCl gives *3,4,6-trichloro-o-toluidine*, m. 89°; *Ac deriv.*, m. 199°; *Bz deriv.*, m. 230°. *p*-$O_2NC_6H_4Me$, chlorinated as above, gives the *2,6-Cl_2 deriv.*, m. 63–4°; HNO_3 and H_2SO_4 give the *3,4-di-NO_2 deriv.*, m. 130°. *2,6-Dichloro-p-toluidine*, m. 55°; *Ac deriv.*, m. 215°, *Bz deriv.*, m. 179° Both of the new Cl derivs. resist oxidation after heating with $KMnO_4$ for 6 days on the water bath. C. J. West

A new color reaction of aromatic amines. I. De Paolini *Gazz. chim. ital.* **60**, 859–62(1930).—Bz_2O_2 (I) is an extremely sensitive reagent for detecting aromatic amines, for it will give a brown-red or violet color reaction with the smallest trace of the amine. This color results from the oxidation of the amine to a quinone, and the reaction has the great advantage over previous color reactions (cf. *Ann.* **27**, 376(1853); *Compt. rend.* **111**, 975(1890); *Ber.* **27**, 3264(1894)) that the oxidation takes place in neutral alc. soln. The reaction of I with aliphatic amines has been studied by Gambarjan (cf. *C. A.* **20**, 372), who found the reaction to be: $I + R_1R_2NH \longrightarrow BzOH + R_1R_2NOBz$. P. has, however, found that with primary amines another aminolysis takes place, thus: $I + RNH_2 \longrightarrow BzO_2H$ (II) + $RNHBz$. II oxidizes in turn a 2nd mol of RNH_2. *E. g.*, $PhCH_2NH_2$ (III) and I yield $PhCH_2NHBz$ (IV), BzH (from the subsequent oxidation of III by II) and $BzONH_2CH_2Ph$ (from combination of III and BzOH, the latter the reduction product of II). Practically, I is added to alc. III until no more is dissolved, and the soln. is dild. with water, which causes pptn. first of BzOH and then of IV. I reacts with other RNH_2 compds., *e. g.*, with alc. NH_2OH or $H_2NNH_2.H_2O$ it forms BzNHOH and $[BzNH]_2$, resp. Gas is evolved in these reactions, because II (which is formed in each case) oxidizes the excess NH_2OH and $H_2NNH_2.H_2O$ to the extent that the mols. are destroyed. In the presence of water and of oxidizable substances, II is formed by the action not only of primary amines, but also of secondary and tertiary amines, as a result of a hydrolysis similar to that with alk. hydroxides, *i. e.*, $I + NaOH \longrightarrow BzONa + II$, as was shown in the present work by using dil. alc. solns. contg. indigo. The great ease of oxidation of aromatic amines to quinones by I probably results from the intermediate formation of II, which in the nascent state is extremely active; in fact the reaction is only feeble in anhyd solvents, *e. g.*, Et_2O or AcMe. The color reaction was obtained with $PhNH_2$, *o-*, *m-* and *p*-$MeC_6H_4NH_2$, asym. *o*-xylidine, *p*-xylidine, *p*-anisidine, *o-* and *p*-$H_2NC_6H_4OEt$, *o-*, *m-* and *p*-$C_6H_4(NH_2)_2$, benzidine, $PhNHCH_2Ph$, PhNHEt, PhNHMe, $PhNMe_2$, $PhNEt_2$, *o-* and *p*-$MeC_6H_4NMe_2$, $PhNEtCH_2Ph$, $MeNPh_2$, *p*-$HOC_6H_4NH_2$, *α-* and *β*-$C_{10}H_7NH_2$, *β*-$C_{10}H_7NHPh$, $Ph_2C(NMe_2)_2$, *o-*, *m-* and *p*-$H_2NC_6H_4CO_2H$, 4,3-Me-

$(H_2N)C_6H_3CO_2H$, 3-bromo-6-aminocuminic acid, 3-aminocuminic acid, 2,4,5-BrMe-$(H_2N)C_6H_3CO_2H$, *o*-, *m*- and *p*-$ClC_6H_4NH_2$, 2,4-$Cl_2C_6H_3NH_2$, *o*-, *m*- and *p*-$BrC_6H_4NH_2$, and *p*-$IC_6H_4NH_2$. In all cases it is best to add the amine to a suspension of I in EtOH, under which conditions a brown-red or violet color appears even when cold, but more rapidly when hot. The reaction is being studied further. C. C. Davis

Asymmetric nitrogen atom. LVIII. Decomposition of active and inactive quaternary ammonium nitrates under the influence of amines; also a contribution to the knowledge of solvate formation by ammonium salts. E. Wedekind and F. Feistel. *Ber.* **63B**, 2743–53(1930); cf. *C. A.* **23**, 5171.—It had been shown that the decompn. of $MePh(PhCH_2)(PhMeNCH_2CH_2)NNO_3$ (I) in $CHCl_3$ is greatly accelerated by amines, secondary bases having a greater influence than primary bases and tertiary bases having little or no effect, whether the I is dissolved directly in the amines or treated in $CHCl_3$ with small quantities of the bases. The reaction was explained as consisting in a primary formation of a solvate (indicated by an increase of the sp. rotation, among other things) which, because of its relative instability, brings about a decompn. of the nitrate into a ditertiary base and $PhCH_2NO_3$ and the latter finally combines with the excess of amine to form a new salt in which an amine H atom is replaced by $PhCH_2$. The renewed salt formation as the result of solvolysis is indicated by a renewed increase in elec. cond. which during the preceding phases decreases along with the rotation. As these expts. were made with a salt (I) which was not completely stable, optically, in $CHCl_3$, they have been repeated with simple active NH_4 nitrates (especially $MePh(PhCH_2)(CH_2{:}CHCH_2)NNO_3$ (II)) and a perchlorate, $Me_2EtPhNClO_4$ (III) (the nitrate is not cryst.), as also with a no. of other amines. To obtain an idea of the qual. decompn. tendency of the halides and nitrates of these NH_4 compds. they were tested for a change in cond. with time. The results in $CHCl_3$ and on addn. of $PhNH_2$, resp., were as follows: (+ indicates decompn., − no decompn., n.t. not tested): $MePh(PhCH_2)(CH_2{:}CHCH_2)NI$ +, n.t.; nitrate (II) −, +. $MePh(PhCH_2)(iso\text{-}Bu)NI$ +, n.t.; nitrate −, +. $MeEtPh(PhCH_2)NI$ +, n.t.; nitrate −, +. $MePrPh(PhCH_2)NI$ +, n.t.; nitrate −, +. *p*-$CH_2[C_6H_4NMeEt(CH_2CH{:}CH_2)]_2Br_2$ (IV) −, −; dinitrate −, −. $Me_2EtPhNI$ (V) −, −; perchlorate (III) −, −. The halides which do not decomp. in $CHCl_3$ (IV, V) also do not react on addn. of $PhNH_2$ and the same is true for the corresponding nitrate and perchlorate. Only those halides decomp. which contain certain groups (Ph and $PhCH_2$ or $CH_2{:}CHCH_2$). Since the nitrates which decomp. on addn. of $PhNH_2$ react essentially alike, kinetic measurements were made first on $MePh(CH_2{:}CHCH_2)NHNO_3$ (VI) and various amines by the method used before (measurement of the decrease in rotation and cond. with time). With 0.1 g. VI and 50 mols. amine in 10 cc. $CHCl_3$ the following half-time values (min.) and av. velocity consts., resp., were obtained. Primary amines: iso-Am 25, 0.0182; iso-Bu 45, 0.0072; Pr 47, 0.0065; Bu 88, 0.0064; $PhCH_2$ 90, 0.0037; Ph 250, 0.0032. Secondary amines: Et_2 26, 0.0259; $Et(PhCH_2)$ 42, 0.0176; $(PhCH_2)_2$ 80, 0.0077; MePh 90, 0.0077; EtPh 150, 0.0055; $Ph(PhCH_2)$ 195, 0.0014; Ph_2 ∞, ——. The tertiary $PhNMe_2$ produced no measurable change in 18 hrs. The relationships between basicity and reaction velocity thus brought out will be discussed elsewhere in connection with further exptl. data. As regards the mechanism of the reaction, and especially the differing behavior of primary and secondary amines on the 1 hand and tertiary amines on the other, it is to be remembered that, according to the hypothesis suggested in connection with the observations on I, the presence of at least one H on the N of the added amine is necessary for the reaction to take place, for it is assumed that a H atom combines with the NO_3 ion to form HNO_3 and is replaced by one of the hydrocarbon residues, leaving a tertiary base: $NR^1R^2R^3R^4NO_3 + H_2NR^5 = NR^1R^2R^3 + R^4NHR^5 + HNO_3$. The HNO_3 may be bound to 1 or both of the bases; it was found that when VI is dissolved in fused *p*-toluidine the cooled solidified mass yields $MeC_6H_4NH_2.HNO_3$, decomps. 199°. The work on I had also led to the conclusion that solvates are formed primarily in the action of amines on the nitrates; the simple method then used for showing their formation (placing the nitrate alone, the amine alone and a mixt. of nitrate and amine in weighed boats and heating them in a high vacuum at gradually increasing temps. up to 111°) was employed in the present work. With those nitrates which decomp. on addn. of the amine, the pure nitrate remained unchanged while the mixt. of nitrate and amine lost wt. until the residue weighed less than the original nitrate, although the presence of amine ($PhNH_2$) could still be detected by the isonitrile reaction. With III and the nitrate corresponding to IV, the wt. of the residue never fell as low as that of the original nitrate or III in the mixt.; there is nothing to prove, however, that these compds. do not also form solvates which are relatively stable as compared with those of the other

nitrates. With tertiary bases ($PhNMe_2$, PhNMeEt) there is no further loss in wt. after the residue has reached the wt. of the original nitrate. No solvate formation between VI and $CHCl_3$ could be detected by this method. The $[\alpha]_D$ of VI in various solvents (Me_2CO 56°, abs. alc. 67°, PhNHMe 73°, $PhNH_2$ 75°, $CHCl_3$ 80°) is smallest in those solvents which are indifferent as regards their influence on the decompn. (Me_2CO, alc.) and highest in those which are known to effect the decompn. In $CHCl_3$, which according to the heating method forms no solvate, the rotation, although higher than in PhNHMe and $PhNH_2$, is independent of the concn., whereas in PhNHMe and $PhNH_2$ it increases with increasing concn. That no solvation occurs in $CHCl_3$ in the absence of an added base was confirmed by f.-p. measurements on II in $CHBr_3$; the mol. wts. found (674.6, 583, at concns. of 2.75, 180) indicated the usual assocn. of NH_4 salts in $CHBr_3$ but gave no evidence whatever of simultaneous solvation. In *p*-toluidine, which causes the decompn. of II in $CHCl_3$, the mol. wt. of II decreases with the length of time it is kept in the molten toluidine until a const. value of 73.40 (calcd. 300.3) is reached, while III, which is not decompd. by the toluidine in $CHCl_3$, gives mol. wts. greater than the calcd. but *decreasing* with increasing concn., indicating the presence of solvates. C. A. R.

Diphenylamine derivatives. K. Dziewoński and M. Russocki. *Bull. intern. acad. polonaise* **1929A**, 506–27.—The conclusions of Merz and Weith (*Ber.* **5**, 283) concerning the proportion of mono- and di-SO_3H acids formed by the action of concd. H_2SO_4 on Ph_2NH are confirmed. With $ClSO_3H$ in $PhNO_2$ below 90°, however, the initial product is the unstable, cryst., $ClSO_3H.NHPh_2$, which at higher temps. readily decomposes, giving nuclear substitution products in accordance with the scheme $Ph_2NHSO_3Cl \longrightarrow Ph_2NSO_3H \longrightarrow PhHNC_6H_4SO_3H$, the proportion of mono- and di-SO_3H acids produced depending on the mol. proportion of $ClSO_3H$ used. Thus with 0.5, 1.0, 1.5 and 2.0 mols. of $ClSO_3H$ for each mol. of Ph_2NH the proportions of mono- and di-SO_3H acids and of unchanged Ph_2NH are, resp., 25, 5, 70, 38, 22, 40; 34, 50, 16; and 0, 99–100, 0 mols. %. Hence with 0.5 mol. of the reagent, diphenylamine-4-sulfonic acid (*aniline salt*, m. 206.5°) is readily sepd. from the reaction mixt. as its Mg salt. Nitration of 4-$PhNHC_6H_4SO_3Na$ with 1 mol. of HNO_3 (d. 1.48) in AcOH gives the *4-nitro-deriv.* (*Mg salt*) converted by hydrolysis with concd. HCl in a sealed tube at 190° into 4-$PhHNC_6H_4NO_2$ (Goldberg, Ger. pat. 185,663(1907)), and further nitrated to *Na 2,4-dinitrodiphenylamine-4'-sulfonate*. Excess of HNO_3 converts 4-$PhNHC_6H_4SO_3Na$ into the 2,4,6-trinitro deriv. identical with a specimen obtained by the condensation of 2,4,6-$Cl_3C_6H_2NO_2$ and sulfanilic acid (Turpin, *J. Chem. Soc.* **59**, 717(1891)) and hydrolyzed by concd. HCl at 180–200° to 2,4,6-$(O_2N)_3C_6H_2NHPh$. The action of Br (2 mols.) on a suspension of 4-$PhNHC_6H_4SO_3Na$ in CCl_4 at 45–50° converts it into its *4-Br deriv.*, while with 6 mols. of Br at 60–70° the product is *Na 2,4,2'-tribromodiphenylamine-4-sulfonate* (*Mg salt*), converted by excess of HBr at 60° into $(2,4\text{-}Br_2C_6H_3)_2NH$ and by dil. HCl at 190° into *2,4,2'-tribromodiphenylamine*, m. 94°, while the action of HNO_3 (d. 1.48) in AcOH at 165 90° yields *2,4,2'-tribromo-6'-nitrodiphenylamine*, m. 215°, together with the corresponding *4',6'-di-nitro deriv.*, m. 179°, and *Na 2,4,2'-tribromo-6'-nitrodiphenylamine-4-sulfonate*. Diphenylamine-4,4'-disulfonic acid (*Mg salt* + $2.5H_2O$, and *aniline salt*, m. 239°) is best obtained by the action of an excess of $ClSO_3H$ on Ph_2NH in $PhNO_2$ at 110–15°. By reactions similar to those described in the case of the mono-SO_3H acid, its Na salt is converted into the *2-nitro-* and *2,2'-dinitrodiphenylamine-disulfonic acids* (converted into $(2\text{-}O_2NC_6H_4)_2NH$, *2,4,2'-trinitrodiphenylaminesulfonic acid*), and $[2,4\text{-}(O_2N)_2C_6H_3]_2NH$, small quantities of the 2,4,6,2',4'-pentanitro- and 2,4,6,2',4',6'-hexanitro derivs. being formed as by-products of the nitrations. Similarly, bromination of 4,4'-$NH(C_6H_4SO_3)_2Ba$ converts it into the *2,2'-di-Br deriv.*, $+0.5H_2O$, together with some *2-Br derivs.*, and, ultimately, into $(2,4\text{-}Br_2C_6H_3)_2NH$. B. C. A.

An improved method of preparation of substituted amides and hydrazides. Sohrab M. Mistry and Praphulla C. Guha. *J. Indian Chem. Soc.* **7**, 793–7(1930).—The condensation between divers types of amines, diamines, hydrazines, thiosemicarbazides, etc., on the one hand and amides such as $CO(NH_2)_2$, $CS(NH_2)_2$, $PhCONH_2$, $C_6H_4(CO)_2NH$ on the other, can be brought about, with excellent yields, by refluxing a mixt. of 1 mol. of the amide and 2 mols. of the amine with sufficient AmOH until the evolution of NH_3 is negligible. With $NH_2NH_2.H_2O$ and $(NH_2)_2CO$ (I), $NH_2NHCONH_2$ is obtained to the exclusion of the expected $(NH_2NH)_2CO$. From I and the requisite amine the following known compds. were prepd.: $(PhNH)_2CO$, $(m\text{-}MeC_6H_4NH)_2CO$, $(p\text{-}MeC_6H_4NH)_2CO$, $(m\text{-}NO_2C_6H_4NH)_2CO$, $(p\text{-}NO_2C_6H_4NH)_2CO$, $(\beta\text{-}C_{10}H_7NH)_2CO$, $(\alpha\text{-}C_{10}H_7NH)_2CO$, $(p\text{-}NHAcC_6H_4NH)_2CO$, $(PhCH_2NH)_2CO$, *o-* and *p*-phenyleneurea

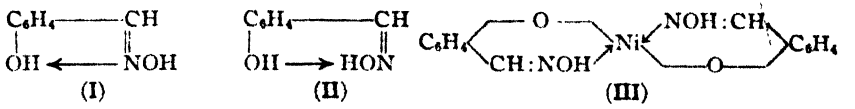
NH.C_6H_4.C_6H_4.NH.CO (from benzidine)(PhNHNH)$_2$CO. With I, *m*-$NH_2C_6H_4OH$ gave (*m*-$HOC_6H_4NH)_2CO$, m. 215°, and *p*-$NH_2C_6H_4OH$ similarly yielded *di-p-hydroxyphenyl urea*, m. 288°. The condensation with I converted *o*-$NH_2C_6H_4COOH$ into *2,4-dihydroxy-tetrahydro-1,2,3,4-quinazoline*, C_6H_4.CH(OH).NH.CH(OH).NH, m. 353° (decompn.). *Di-p-nitrophenylcarbohydrazide*, (*p*-$NO_2C_6H_4NHNH)_2CO$, m. 361° and *di-p-bromophenyl carbohydrazide* were made from *p*-$NO_2C_6H_4NHNH_2$ and *p*-$BrC_6H_4NHNH_2$, resp. The treatment of $NH_2NHCSNHPh$ with I by this method gave 3 compds.: *1-phenyl-2-phenylamino-5-thiol-1,3,4-triazole*, PhN.C(NHPh):N.N:CSH, m. 210°, *2,5-endoxy-1,3,4-triazole*, NH C:N.N:C.O, 250° and *2-keto-5-phenylamino-2,3-dihydro-1,3,4-thiodiazole*, S.CO.NH N:CNHPh, m. 246°. *p*-$AcNHC_6H_4NH_2$ (II) formed $AcNHC_6H_4NHCONHPh$ with $NH_2CONHPh$ and $(AcNHC_6H_4NH)_2CS$ with $(NH_2)_2CS$ (III). III gave $(PhNH)_2CS$ with $PhNH_2$ (IV) but formed $NH_2NHCSNHPh$ with PhNHNH$_2$ (V). $(NH_2CO)_2$ condensed with II, IV and V to yield (*p-AcNHC$_6$H$_4$NHCO*)$_2$, m. above 370°, (*PhNHCO*)$_2$ and (*PhNHNHCO*)$_2$. II, IV and V gave (*p*-$AcNHC_6H_4NHCO)_2CH_2$, m. 235°; $CH_2(CONHPh)_2$ and $CH_2(CONHNHPh)_2$ with $CH_2(CONH_2)_2$ and when condensed with $(CH_2CONH_2)_2$ yielded (*p-AcNHC$_6$H$_4$NHCOCH$_2$*)$_2$, m. 317° (decompn.), $(PhNHCOCH_2)_2$ and $PhNHNHCOCH_2)_2$. AcNHPh was obtained in 80% yield from $AcNH_2$ and IV, on complete removal of AmOH and crystn. of the residue from hot H_2O. C. R. ADDINALL

Chlorination of iodophenols. III. Chlorination of *o*-iodophenol. SAMUEL BUCHANAN AND HAMILTON MCCOMBIE. *J. Chem. Soc.* **1931**, 137-44; cf. *C. A.* **7**, 1706.—o-IC_6H_4OH (I) in CCl_4 gives on chlorination a sequence of unstable iododichlorides and decompn. products very similar to those obtained from the *p* isomer. I *acetate*, oil; dichloride, m. 92-3° (decompn.), unstable. I *benzyl ether*, oil; the dichloride unstable. I *benzoate*, m. 34°; *dichloride*, m. 98-101° (decompn.), stable. I *phenyl carbamate*, m. 121-2°; Cl in $CHCl_3$ gives the *dichloride*, m. 125° (decompn.) of *2-iodophenyl 2,4-dichlorophenylcarbamate*, m. 145°; its constitution was proved by its synthesis from the 2 components. A 10% soln. of I in CCl_4, satd. with dry Cl at 0°, gave *4-chloro-2-iodophenol* (II), m. 78°; its constitution was established by synthesis from 4,2-Cl(O$_2$N)C$_6$H$_3$OH; whose *benzyl deriv.*, m. 84-5°. II *acetate*, oil; the dichloride decomps. rapidly. II *benzyl ether*, m. 60°; dichloride, decomps. 95-7°, decomps slowly over 4-5 days. II *benzoate*, m. 88°; *dichloride*, stable, m. 103-4° (decompn.). II *phenylcarbamate*, m. 128°; Cl in $CHCl_3$ gives the *compd* $C_{13}H_7O_2NCl_3I$, m. 146°. Further chlorination of II in CCl_4 gives *4,6-dichloro-2-iodophenol* (III), m. 62°; this is more easily obtained by rapid chlorination of I. III *acetate*, m. 59°, the dichloride decomps. in 5-6 days. III *benzyl ether*, m. 62°; the dichloride decomps. over several days. III *benzoate*, m. 89°; chlorination does not give the dichloride. III *phenyl carbamate*, m. 181°; no dichloride pptd. with Cl but HCl was evolved. Further chlorination of III gives a small amt. of the *tri-Cl deriv.*, m. 52-4°. *2-Iododiphenyl ether*, m. 55-6°, results from the NO_2 deriv. by reduction and the Sandmeyer reaction; the *dichloride*, m. 81-2° (decompn.), is unstable and decomps. in 2 days. *ω 2'-Iodophenoxyacetophenone*, m. 123°, from I and $BzCH_2Cl$; dichloride, m. 98° (decompn.), moderately stable. I and $COCl_2$ in pyridine give *di-2-iodophenyl carbonate*, m. 88°; *dichloride*, m. 108° (decompn.), stable. I *p-toluenesulfonate*, m. 80°; *dichloride*, m. 95-7° (decompn.), stable. I *allyl ether*, oil; Cl gives the *compd*. $C_9H_9OCl_4I$, m. 81° (decompn.), slowly decomps. in the air. I *dibromopropyl ether*, oil; the *dichloride*, m. 118° (decompn.), decomps. slowly in 4 weeks, giving *4-chloro-2-iodophenyl dibromopropyl ether*, m. 52°. I *Et carbonate*, oil; a dichloride could not be prepd. Chlorination of I in CCl_4 at 60-70° gives chloranil and hexachlorocyclohexadienone. *p*-ClC_6H_4OH and ICl give *4-chloro-2,6-diiodophenol*, m. 106-7°; the dichloride is unstable. Chlorination of a 10% soln. of $PhNHCO_2Ph$ in $CHCl_3$ at 0° gives *4-chlorophenyl 2,4-dichlorophenylcarbamate*, m. 157°; its structure was established by condensing *p*-ClC_6H_4OH with *2,4-dichlorophenylcarbimide*, m. 61°. C. J. WEST

Chlorination and nitration in methanol as a medium. E. PLAZEK. *Roczniki Chem.* **10**, 761-76(776 German)(1930).—In order to investigate the possibility of introducing MeOH as a solvent and diluent in the chlorination and bromination of various compds., PhOH, *m*-cresol, PhOMe, 2- and 3-$HOC_6H_4CO_2H$, benzoic acid, 4-$NO_2C_6H_4OH$, 1,2-acetylphenylenediamine, 4-sulfophenol, 4-$NO_2C_6H_4NH_2$, 2-$NO_2C_6H_4NH_2$

2- and 4-$H_2NC_6H_4CO_2H$ were chlorinated and PhOH, *m*-cresol, 4-ClC_6H_4OH, 2-ClC_6H_4OH, veratrole and *p*-$C_6H_4(OMe)_2$ nitrated in MeOH as a medium. MeOH was found to be a good solvent in chlorinations, equal in value to AcOH; it possesses the advantage of greater volatility and can be more easily regenerated. In some cases the influence of temp. and diln. on the course of chlorination was investigated and found to be insignificant. Analogous expts. with EtOH showed that this solvent is much inferior to MeOH in chlorination and quite unsuitable in nitration. Nitration in MeOH could be performed with success only in the case of PhOH and its derivs., especially 2- and 4-ClC_6H_4OH, veratrole and *p*-$C_6H_4(OMe)_2$. J. KUČERA

New method of reducing aromatic nitro compounds. THEODORA E. DE KIEWIET AND HENRY STEPHEN. *J. Chem. Soc.* **1931**, 82–4.—Cryst. $SnCl_2$ is dehydrated with Ac_2O and the nitro compd. added and heated until soln. results; in this way, *e. g.*, $PhNO_2$ gives nearly quant. *p*-ClC_6H_4NHAc. Difficulty was experienced in the isolation of the anilides resulting from the reduction of *m*-substituted NO_2 compds. and it was found necessary to isolate the free bases by steam distn. in alk. soln. A 30% yield of the anilides may be obtained if the residue after removal of the AcOH is extd. with hot C_6H_6. *3-Chloro-6-acetamidophenol*, m. 186°, and *3-chloro-4-acetamidophenyl acetate*, m. 127°, result by the reduction of 3,6- and 3,4-$Cl(O_2N)C_6H_3OH$. In *p*-substituted NO_2 compds. no chlorination takes place except in the case of *p*-$ClC_6H_4NO_2$ which, only if HCl is present during the reduction, gives 2,4-$Cl_2C_6H_3NHAc$. The reduction of *o*-$O_2NC_6H_4OH$ and certain of its derivs. yielded in each case a *N*-Ac deriv., although sufficient Ac_2O was present to acetylate the HO group. α-Methylbenzoxazoles may be intermediate products in their reduction The reduction products isolated from a no. of compds are listed C. J. WEST



The production of *p*-aminophenol. JULIUS ALTPETER. *Metallborse* **20**, 2803–4 (1930); **21**, 27–8 (1931).—A review is given of the various methods devised for the production of *p*-$NH_2C_6H_4OH$ (I), and of the reactions in which I is a product. Short descriptions are given of the reduction of *p*-$NO_2C_6H_4OH$ by means of metal and acid combinations, by P, I and HCl, by the use of Na_2S, and by catalytic hydrogenation, and of the employment of metal-acid combinations and of Na_2S in the reduction of *p*-NOC_6H_4OH. Prepns. depending on the cleavage of azo compds. include the reduction of *p-dihydroxyazobenzene* by $SnCl_2$ in acid soln., Zn and NaOH and alk. Na_2S. *Benzeneazophenol* (II) in Na_2CO_3, treated with H_2S, gives a mixt. of $PhNH_2$ and I. Other methods for the cleavage of II include treatment with alc. NH_3 satd with H_2S, reduction with metal-acid combinations and fusion with NH_2NHPh. By the reduction of 4,4'-$HOC_6H_4N{:}NC_6H_4SO_3Na$ with Fe and H_2SO_4 80% of I and 95% of $NH_2C_6H_4SO_3H$ are obtained The reduction can also be carried out with Fe and NaCl The *disazo dye* formed by coupling 2 mols of PhOH with tetraazodiphenyl can be cleaved by catalytic hydrogenation into $(C_6H_4NH_2)_2$ and I. Under the heading of various methods of prepn. and formation of I are listed the change of *p*-ClC_6H_4OH into I by NH_4OH and $CuSO_4$; the conversion of PhN_2 by the action of H_2SO_4 in the presence of AcOH; the oxidation of PhNH by $K_2Cr_2O_7$ and of $HO_3SC_6H_4NH_2$ by MnO_2 and H_2SO_4; the transformation of PhNHOH on heating with acid, and a similar transformation following the soln. of $PhNO_2$ in a soln. of S in 35–40% oleum at 20°; the reaction of NOCl with C_6H_6 in the presence of $AlCl_3$; the action of H_2O_2 on $PhNHMgBr$ in Et_2O; the hydrolyses of *N*-phenyl-α-indole oxime and phenolphthalein oxime by 25% H_2SO_4; the cleavage of nitrones and the distn. of 5,2-$H_2N(HO)C_6H_3CO_2H$. The original method of Gattermann for the prepn. of I by the electrolysis of a soln. of NO_2Ph in H_2SO_4 has been modified in many ways. The various changes involving cell construction, electrodes, solns., temp., agitation, c. d., time, by-products of the reaction, etc., are summarized. C. R. A.

Reaction of *p*-anisidine and ethyl methylacetoacetate. WM. O. KERMACK AND JAMES F. SMITH. *J. Chem. Soc.* **1931**, 221–2.—*p*-$MeOC_6H_4NH_2$ (I) and $AcCHMeCO_2Et$ (II) appear to give a *compd.*, $C_{21}H_{28}O_4N_2$, formed from 2 mols. I and 1 mol. II, m. 51°; this is confirmed by analysis, its gradual decompn. in a stoppered bottle, its behavior with Ac_2O and mol.-wt. detn. C. J. WEST

Preparation of an *o*-aminothiophenolsulfonic acid. JAKOB POLLAK AND KARL DEUTSCHER. *Monatsh.* **56**, 365–80 (1930).—$(2\text{-}H_2NC_6H_4)_2S_2$ is decompd. by $ClSO_3H$ at −20° and by fuming H_2SO_4 under various conditions. Phenylenediazosulfide is unaffected by fuming H_2SO_4 (25–70% SO_3) at 160–70°. *o*-$H_2NC_6H_4SH$ could not be sulfonated. 4,3-$Cl(O_2N)C_6H_3SO_2K$ and Na_2S_2 in 96% EtOH give *K 2,2'-dinitrodiphenyl disulfide-4,4'-disulfonate;* in H_2O reduction occurs with either Na_2S or Na_2S_2. The Ba salt of 4,3-$Cl(O_2N)C_6H_3SO_2H$ and K xanthate in H_2O give EtOH, Et xanthate, CS_2 and the *Ba salt* (I) of 2,2'-dinitrodiphenyl sulfide-4,4'-disulfonic acid (II), crystg. with 5 mols. H_2O; with $AcONH_4$ only a small amount of the sulfide is produced. II

and PCl_5 give the *dichloride* of II, orange-yellow, m. 195°, crystg. with 0.5 mol. C_6H_6; oxidation of the chloride with fuming HNO_3 gives *2,2'-dinitrodiphenyl sulfone-4,4'-disulfonic acid*, whose *Pb salt* crystallizes with 3 mols. H_2O and whose *Ba salt* also crystallizes with 3 mols. H_2O; this also results by the oxidation of I. Reduction of I with Sn and HCl gives *2,2'-diaminodiphenyl sulfide-4,4'-disulfonic acid*, crystallizes with 3 mols. H_2O and readily oxidizes in the air. The diazo compd. gives a red disazo dye with β-$C_{10}H_7OH$. Treatment of the reaction product from 4,3-$Cl(O_2N)C_6H_3SO_2Na$ and $Na_2S_2O_3$ with PCl_5 also gives the chloride; when the K sulfonate is treated similarly *Na 2,2'-dinitrodiphenyl sulfide-4,4'-disulfonate* is obtained. 4,3-$Cl(O_2N)C_6H_3SO_2K$ and KHS, heated in H_2O, the soln. evapd. to dryness and the residue reduced with Sn and HCl, give 75% of *2-aminothiophenyl-4-sulfonic acid;* $NaNO_2$ gives a diazo compd. which does not couple with β-$C_{10}H_7OH$. With the K sulfonate there results *K 5-nitrophenothiazine-3,8-disulfonate*, crystg. with 2 mols. H_2O. Numerous attempts to prep. the acid with other S-contg. salts were unsuccessful. C. J. West

Coördination compounds of oximes. II. Nickel and cobalt compounds of *o*-hydroxybenzaldoxime. Oscar L. Brady. *J. Chem. Soc.* 1931, 105–7; cf. *C. A.* **24**, 5296.—*o*-$HOC_6H_4CH:NOH$ (I) has all the properties of a coördination compd. and probably should be formulated as I, rather than II, because it yields a NOAc deriv.

(I) (II) (III)

with Ac_2O at room temp. The *Ni salt*, dark green needles, and the *Co salt*, dark brown powder, are of the the type III. No evidence of the β-isomers could be obtained. Under the conditions specified by Ephraim (*C. A.* **24**, 5665) for the detn. of Cu by I, Ni salts give some ppt.; the presence of salts of weak acids in any quantity would also invalidate the method. C. J. West

Action of mustard oils on oximes. An. Obregia and C. V. Ghrorghiu. *J. prakt Chem.* **128**, 239–319(1930).—α-PhCH:NOH (I) and PhNCS (II) at room temp. in a sealed tube give COS, PhCN and $(PhNH)_2CS$; in boiling C_6H_6 the reaction products are the same, while if the 2 compds. are heated without a solvent to 80°, COS is evolved and S and $(PhNH)_2CO$ are isolated; in EtOH-KOH, $(PhNH)_2CO$, $(PhNH)_2CS$ and $PhNHCO_2N:CHPh$ are the products. The β-oxime and II, heated to 120°, evolve COS and give $(PhNH)_2CO$. In a sealed tube at room temp., there results COS and $(PhNH)_2CS$. In alk. medium, the products are S, PhCN and $(PhNH)_2CS$. I and *o*-MeC_6H_4NCS in C_6H_6 at room temp. give $(o\text{-}MeC_6H_4NH)_2CS$ (III), m. 158°. In a sealed tube, COS, III and PhCN were obtained, while in alk. reaction the products are *carbo-o-toluido-α-benzaldioxime*, m. 124°, and $(o\text{-}MeC_6H_4NH)_2CO$, m. 158°. I and *p*-$MeC_6H_4NCS$ behave similarly. MeCH:NOH and II give COS and $(PhNH)_2CS$ in a sealed tube or in an open vessel; in EtOH or C_6H_6, autoxidation and decompn take place. *o*-MeC_6H_4NCS give S and III. In *o*-$HOC_6H_4CH:NOH$ only the oxime group reacts with II; in alk. soln. the products are the nitrile and $(PhNH)_2CS$; the possible reactions involved in the formation of the nitrile are discussed. *p*-$MeOC_6H_4CH:NOH$ and II in EtOH at room temp. give the nitrile and $(PhNH)_2CS$; the β isomer behaves in the same manner. Furfur-*syn*-aldoxime and II in EtOH-KOH give $(PhNH)_2CS$, $(PhNH)_2CO$, S and the nitrile; the *anti*-oxime behaves similarly in EtOH, while with alkali there results the carbanilino deriv., m. 138°, identical with that obtained by the use of PhNCO. *o*-MeC_6H_4NCS gives only $(o\text{-}MeC_6H_4NH)_2CO$. $Me_2C:NOH$ and II in EtOH at room temp. give $Me_2C:NOCONHPh$, m. 108°, and S. *o*-MeC_6H_4NCS gives *carbo-o-toluidoacetoxime*, m. 81–2°; the *p-deriv.* m. 105–6°. MeEtC:NOH and II, without a solvent, give the *carbanilino deriv.*, $MeEtC:NOCONHPh$, m. 135°; this also results in Me_2CO soln.; in alk. soln. there is also formed $H_2S_2O_3$ or its decompn. products, H_2SO_3 and S. If the reacting compds. are heated, there results the carbanilino deriv. and $(PhNH)_2CS$. *o*-MeC_6H_4NCS gives *carbo-o-toluido methyl Et ketoxime*, m. 80°; the *p-isomer* m. 146–7°. *Carbanilinodiethyl ketoxime*, m. 96–8° (25% yield); *methylpropyl deriv.*, m. 146° (13% yield). Me iso-Bu ketoxime, b. 175°, d_4^{17} 0.8935, n_D^{14} 1.456; *carbanilino deriv.*, m. 117° (20% yield); *carbo-o-toluido deriv.*, m. 184°. MePhC:NOH gives a carbanilino deriv., m. 131.5°; *carbo-o-toluido deriv.*, m. 109°; *p-isomer*, m. 126°. *Carbanilinoresacetophenoxime*, pale yellow, m. 118–20°; *o*-MeC_6H_4NCS did not react. $Ph_2C:NOH$ gives $Ph_2C:NOCONHPh$, m. 176°. $(Me_2NC_6H_4)_2C:NOH$ did not react with II or the *o*-Me deriv. *Carbanilino methyl p-tolyl ketoxime*, m. 112°. Monoximes of diketones do not react with II; α

isonitroso acids, such as $AcC(:NOH)CH_2CO_2H$ or $PhC(:NOH)OH$, also do not react with II. C. J. WEST

The constitution of certain compounds formed by the action of alcoholic hydrochloric acid on unsaturated ketones. BRIAN COFFEY AND HUGH RYAN. *Proc. Roy. Irish Acad.* **B39**, 434–9(1930); cf. *C. A.* **23**, 3213; **24**, 5293.—The dimer formed by the action of alc. HCl on $PhCH:CHCOEt$ (I) yields a monoxime (II), m. 242–3°. II is reconverted into I by treatment with concd. H_2SO_4 or by boiling with alc. HCl and is unchanged by further treatment with $NH_2OH.HCl$ (III), hence it is assumed that I is $CHPh.CHPh.CH(COEt).CHCOEt$ instead of the sym. $EtCOCH.CHPh.CH(COEt).CHPh$. The compd. formed by treating II with P_2O_5 appears to be $EtCOCH.CHPh.CHPh.CHCONHEt$ (IV). IV does not absorb Br_2 nor react with III. Heated with dil. H_2SO_4, extd. with Et_2O, PhH and $CHCl_3$, neutralized with KOH, distd. and the distillate tested with I_2 in NaOH, IV gave the CHI_3 test but none of the exts. left any residue. C. H. PEET

2-Hydroxy-4-methoxy- and 4-hydroxy-2-methoxybenzaldehyde. THEODORA ELIZABETH DE KIEWIET AND HENRY STEPHEN. *J. Chem. Soc.* 1931, 84–5.—*m*-$MeOC_6H_4OH$ (20 g.) in 70 cc. abs. Et_2O and 20 g. HCN, satd. with dry HCl and kept in a refrigerator for not more than 24 hrs. and the pptd. aldimine-HCl dissolved in 2 l. cold H_2O and heated to boiling, give 9.5 g. 2,4-$HO(MeO)C_6H_3CHO$ (I), removed in a current of steam, and 10 g. of 4,2-$HO(MeO)C_6H_3CHO$ (II). II *phenylhydrazone*, yellow, m. 158°; *p-nitrophenylhydrazone*, dark red, m. 255° (decompn.); *semioxamazone*, m. 242°. I *p-nitrophenylhdrazone*, bright red, m. 226.5°; *semioxamazone*, lemon-yellow, m. 247°; *semicarbazone*, m. 230°. C. J. WEST

Condensation of aldehydes with hydrazones. II. Condensation of anisaldehyde and of salicylaldehyde with their respective phenylhydrazones. ANTONINO GIACALONE. *Gazz. chim. ital.* **60**, 818–21(1930).—The expts. are in continuation of the previous ones (cf. *C. A.* **24**, 837) and employ the same method. Each aldehyde can condense with its own phenylhydrazone or with the phenylhydrazone of another aldehyde, so that from BzH, *p*-$MeOC_6H_4CHO$ (I), *o*-HOC_6H_4CHO (II) and phenylhydrazine, 9 condensation products can be obtained. The earlier paper and present paper describe 3 of these; the remainder will be described in later papers. I (3 mols.), mixed with $PhHNNH_2$ (III) (2 mols.), when the reaction is completed $ZnCl_2$ (10 g.) added, heated on a water bath until the mixt. becomes thoroughly hard, finely ground, washed with steam (to remove I), dried in the air, extd. with boiling C_6H_6 and the residue recrystd. from boiling PhMe, yields *p,p'-dimethoxydibenzal-p,p'-dihydrazino-p''-methoxytriphenylmethane*, $MeOC_6H_4CH(C_6H_4NHN:CHC_6H_4OMe)_2$, pale violet, m. 215–6°. Following the same procedure except that the hardened mass is washed with boiling EtOH instead of C_6H_6 before recrystn. from boiling PhMe, II (3 mols.) and III (2 mols.) yield *o,o'-dihydroxydibenzal-p,p'-dihydrazino-o-hydroxytriphenylmethane*, $HOC_6H_4CH(C_6H_4NHN:CHC_6H_4OH)_2$, yellow, blackens 235°, m. 240°, sol. in dil. aq. NaOH from which solns. it is repptd. by acids. **III. Condensation of salicylaldehyde, of anisaldehyde and of *p*-nitrobenzaldehyde with benzalphenylhydrazine.** *Ibid* 821–4.—*o*-HOC_6H_4CHO (5 g.) and $PhCH:NNHPh$ (I) (16 g.) treated with $ZnCl_2$ (5 g.) and a little PhMe to make a uniform paste, heated on a water bath, with agitation until the fused reaction mixt. becomes green and solidifies, a little water added, heated further, finely ground, washed with steam, dried in the air, dissolved in hot C_6H_6, filtered and cooled, ppts. *p,p'-dibenzaldihydrazino-o-hydroxytriphenylmethane*, $HOC_6H_4CH(C_6H_4NHN:CHPh)_2$ (II), m. 185°, insol. in dil. aq. NaOH (suggesting that the OH has taken part in the reaction, but this is disproved by the formation of an Ac deriv.). II, Ac_2O and fused AcONa refluxed 3 hrs., poured into water, let stand until solidified, dried, pulverized, dissolved in AcOH, poured into water and dried in air and then over H_2SO_4 in a desiccator, yield the *Ac deriv.*, $AcOC_6H_4CH(C_6H_4NAcN:CHPh)_2$, m. 109–10°. Similarly anisaldehyde (5 g.), phenylhydrazine (14.5 g.) and $ZnCl_2$ (5 g.), heated until hard, steam-distd., the residue washed with EtOH, dissolved in C_6H_6 and poured into ligroin, ppts. *p,p'-dibenzaldihydrazino-p''-methoxytriphenylmethane*, $MeOC_6H_4CHC_6H_4NHN:CHPh)_2$, yellow, amorphous, m. around 125°, could not be crystd. from any solvent. *p*-$O_2NC_6H_4CHO$ (2 g.), I (5.2 g.) and $ZnCl_2$ (2 g.), heated as before until hard, pulverized, boiled with water and then with EtOH, the residue purified by soln. in hot PhMe, yield *p,p'-dibenzaldihydrazino-p''-nitrotriphenylmethane*, $O_2NC_6H_4CH(C_6H_4NHN:CHPh)_2$, orange-yellow, m. 213–4°. C. C. DAVIS

A simple method for the preparation of phenylglyoxal. CARL NEUBERG AND EDUARD HOFMANN. *Biochem. Z.* **229**, 443–5(1930).—The following reaction is utilized

for the prepn. of phenylglyoxal: $PhCOCH{:}NOH + ONO.SO_3H = PhCOCHO + N_2O + H_2SO_4$. Ten g. of PhCOCH:NOH is dissolved in 35 cc. dioxane, dild. with 10 cc. H_2O and cooled to 0°. With const. shaking 8.5 g. of $NO_2.SO_3H$ crystals is added while the temp. is kept below 5°. Then the mixt. is warmed up to 40°, whereupon a vigorous reaction and evolution of gas occur. The flask must be kept in cold water to prevent the temp. from rising above 60°. This is now transferred with about 100 cc. H_2O to a Claisen flask and evapd. to 70 cc. *in vacuo*. The oily residue is extd. 3 times with 50 cc. ether, and the combined ether exts. are washed several times with small quantities of H_2O. After removing the ether the PhCOCHO is extd. from the oil by boiling twice with 40-cc. quantities of H_2O. The hot soln. is filtered and evapd. *in vacuo* to 30 cc., and on cooling with ice massive crystallization occurs. S. MORGULIS

Dimethylallylbenzylacetic acid and isopropylbenzylvalerolactone. G. DARZENS AND A. LÉVY. *Compt. rend.* **191**, 1455-7(1930); cf. *C. A.* **21**, 581.—$Me_2C{:}CHCH_2OH$ with HBr gas gives $Me_2C{:}CHCH_2Br$, b 120°, which with $PhCH_2CNa(CO_2Et)_2$ gives $Me_2C{:}CHCH_2C(CH_2Ph)(CO_2Et)_2$, b_9 184-7°. This ester on saponn. and heating *in vacuo* to 160° gives 80% $Me_2C{:}CHCH_2C(CH_2Ph)CO_2H$, b_7 157-60°, m. 49.5°, and 20% lactone, m. 25° and b_8 148-50°. This does not condense to give a hydronaphthalene deriv. V. F. HARRINGTON

Spectrochemical study of amino acid anhydrides. IV. Light absorption of derivatives of azlactones, diketopiperazine, hydantoin and thiohydantoin. TIE-ICHI ASAHINA. *Bull. Chem. Soc. Japan* **5**, 354-65(1930); cf. *C. A.* **24**, 298.—The ultraviolet absorption of azlactones of substituted hippuric acids, RCH:C(CO)O(CPh)N where R is *o*- (I), *m*- (II), or *p*-$AcOC_6H_4$ (III), *o*- (IV), *m*- (V), or *p*-$MeOC_6H_4$ (VI); of RCH:C(CO_2H)NHCOPh, where R is furyl (VII), Ph (VIII), *o*-, *m*- or *p*-HOC_6H_4 (XV), *o*-, *m*- or *p*-$MeOC_6H_4$ (XVI); dibenzal- (IX), and difuraldiketopiperazine (X); 4-benzal (XI), and 4-furalhydantoin (XII); 2-thiohydantoin and its following derivs.: 3-acetyl, 3-benzoyl, 3-acetyl-4-benzyl, 4-benzyl, 4-(*p*-hydroxybenzyl), 4-benzal (XIII) and 4-fural (XIV). VII, X, XII and XIV are more bathochromic and hyperchromic than VIII, IX, XI and XIII. I, II and III have an absorption max. near 3580 A. U. IV and VI have the same max. while V is less bathochromic. The azlactones are far more bathochromic than their hydrolysis products, XV and XVI. Absorption curves and methods of prepn. are given. V. F. HARRINGTON

Esterification of 3,5-diamino- and iodobenzoic acids with alcoholic hydrogen chloride. ANTON KAILAN AND ADOLF IRRESBERGER. *Monatsh.* **56**, 407-27(1930).—The unimol. velocity coeffs. of esterification of 3,5-$(H_2N)_2C_6H_3CO_2H$ (I) and *o*-, *m*- and *p*-$IC_6H_4CO_2H$ with EtOH-HCl in the presence and absence of H_2O have been detd. at 25°. With EtOH contg. little H_2O the coeffs. for all the acids are proportional to the concn. of the HCl; in moist EtOH the coeffs. increase much more rapidly. The values for I show that the introduction of a 2nd *m*-NH_2 group into BzOH has a much smaller effect than the first. The retarding action of the halogen atom is most marked with the *o*-I acid and least with the *m*-isomer. For the *o*-halogenobenzoic acids, the coeff. decreases with increasing at. wt. of the halogen atom. All the *m*-halogeno acids have approx. the same coeff., which is less than that for BzOH. C. J. WEST

Behavior of some condensation products of *p*-dimethylaminobenzaldehyde toward bromine and nitrous acid. K. H. BAUER AND MARIE SEYFARTH. *Ber.* **63B**, 2691-5 (1930).—It had been shown that the condensation products of BzH with $PhCH_2CN$, $NCCH_2CO_2Et$ and other compds. do not add Br normally but are unreactive toward it. To det. whether this behavior is influenced by introduction of a Me_2N group into the Ph nucleus, the condensation products of *p*-$Me_2NC_6H_4CHO$ with $PhCH_2CN$, $NCCH_2CO_2Et$, $CH_2(CN)_2$, MeCOPh and Me_2CO were treated with Br and HNO_2. With *p*-$Me_2NC_6H_4CH{:}CPhCN$ (I), *p*-$Me_2NC_6H_4CH{:}C(CN)CO_2Et$ (II), *p*-$Me_2NC_6H_4CH{:}C(CN)_2$ (III) and *p*-$Me_2NC_6H_4CH{:}CHCOPh$ (IV), for the most part no Br or N_2O_3 is added at the double bond but Br is substituted in the $Me_2NC_6H_4$ nucleus in the *o*-position to the Me_2N group, as was shown by synthesis of the products, and N_2O_3 gives the corresponding NO_2 derivs. The yields in all cases were 60-75%. When, however, the PhCO group in IV is replaced by MeCO, *i. e.*, with *p*-$Me_2NC_6H_4CH{:}CHCOMe$, there is formed, by primary addn. of Br at the double bond and subsequent elimination of HBr, ***α-p-dimethylaminophenyl-β-bromo-β-acetylethylene*** **(V)**, whose ***phenylhydrazone*** **(VI)** rearranges in AcOH on the H_2O bath into ***N-phenyl-3-methyl-5-p-dimethylaminophenylpyrazole*** **(VII)**, with loss of H_2O. ***α-Phenyl-p-dimethyl-m-bromocinnamonitrile***, from 3,4-$Br(Me_2N)C_6H_3CHO$ and $PhCH_2CN$ with a few drops KOH in alc. or from I with Br in $CHCl_3$, green-yellow, m. 102°. ***m-Nitro analog***, similarly prepd. from 3,4-$O_2N(Me_2N)C_6H_3CHO$ and $PhCH_2CN$ or from I with $NaNO_2$ in AcOH.

deep red, m. 128°. *Et α-cyano-β-dimethylamino-m-bromocinnamate*, light yellow, m. 107°; *m-nitro analog*, m. 172–3°. *(p-Dimethylamino-m-bromobenzal)malononitrile*, golden yellow, m. 123–4°; *m-nitro compd.*, orange-yellow, m. 147–8°. *(p-Dimethylamino-m-bromobenzal)acetophenone*, pale green-yellow, m. 82°. V, light yellow, m. 92°. VI, green, m. 127°. VII, m. 148–50°, gives the Knorr pyrazoline reaction after reduction with Na and alc. C. A. R.

The mechanism of the action of organomagnesium compounds on the *N*-disubstituted amides of α,β-unsaturated acids. COSTIN D. NENITZESCU. *Bul. soc. chim. Romania* **12**, 48–57(1930).—N. shows errors in the work of Maxim and Ioanid (cf. *C. A.* **23**, 2697; **22**, 4114). M. and I. condensed PhCH:CHCONEtPh with PhMgBr and added AcCl and reported that they obtained the unsatd. ester 3,3-diphenyl-1-ethylphenylamino-Δ¹-1-propenol acetate (I). N. repeated this work and finds that the product is not unsatd. since it does not decolorize Br water or alk. $KMnO_4$ but does yield with $PhNHNH_2$ a hydrazone, m. 178°, which shows that the compd. possesses a ketone group and must be $Ph_2CHCHAcCONEtPh$ (II). Synthesis of II as indicated by the scheme: $Ph_2CHBr + NaOC(Me):CHCO_2Et \longrightarrow Ph_2CHCHAcCO_2Et + PhNHMe \longrightarrow$ II, a compd. which melts at the same point as M. and I.'s compd. to which they give formula I, but yields a hydrazone m. 178° and identical with the hydrazone from II. In the same way M. and I. have erred in the constitution of the products of methyl- and phenylanilides of cinnamic acid with PhMgBr and AcCl. N. also points out that the work of M. and I. is almost an identical repetition of the earlier work of Köhler and Heritage [*Am. Chem. J.* **33**, 21(1905)] and that M and I. apparently did not know of the work of Claisen (*Ann.* **277**, 171) and others showing that AcCl gives a *C*-deriv. instead of an *O*-deriv. or they would not have fallen into this error. N. attempted to prep. the *O*-deriv. by treating the condensation product of PhCH:CHCONEtPh and PhMgBr with $ClCO_2Et$ but obtained a yellow oil which he did not succeed in crystg. but which decolorized Br water and is probably an enol *O*-deriv. Maxim (cf. *C. A.* **24**, 2427) condensed MeCH:CHCONPh₂ with MeMgI and obtained iso-BuCONPh₂ in 1.2 percent yield and a compd $C_{37}H_{34}O_2N_2$ (III) to which M. assigns the formula $MeCH(NPh_2)CH(CONPh_2)COCH_2CHMe_2$ (IV) in 80% yield. M. reports that hydrolysis of IV gives 2 compds. (one from acid hydrolysis and one from alk. hydrolysis) m. 158° and 153°, which are stereoisomers. N. repeated the work of M. but on hydrolysis of 1 g. of III with 10 cc. of 49% HBr obtained Ph_2NH and α-methyl-β-isopropylglutaric acid (V), m. 116–7°. (This name seems to be in error in the paper and should be β-methyl-α-isopropylglutaric acid.) On alk. hydrolysis of III N. obtained a compd. VI, m. 156° which is probably a mixt. of III and III partially hydrolyzed, *e. g.*, at one of the CO_2H groups. Treatment of VI with 15 cc. 49% HBr yielded V. N. attributes the errors of M. to incomplete hydrolysis of III. N. explains the formation of III by the following scheme and shows its constitution to be represented by VII rather than IV. $MeCH:CHCONPh_2 + MeMgI \longrightarrow Me_2CHCH:C(OMgI)NPh_2$ (VIII) + $MeCH:CHCONPh_2 \longrightarrow Me_2CHC(CHMeCH_2CONPh_2):C(OMgI)NPh_2 + H_2O \longrightarrow Me_2CHCH(CHMeCH_2CONPh_2)CONPh_2$ (VII) + MgIOH. VIII possesses enolic properties and adds on to a 2nd mol. of $MeCH:CHCONPh_2$. The mechanism of addn. of organomagnesium compds. to *N*-disubstituted amides of both cinnamic and crotonic acids is at the ends of the conjugated system C:C.C:O and in accord with the work of Köhler and Heritage. ODEN E. SHEPPARD

Two modifications of *p*-hydroxybenzoic acid methyl ester. LUDWIG KOFLER AND ADELHEID KOFLER. *Mikrochemie* **3**, 44–51(1931).—If the ester is sublimed and cooled, crystals are obtained which m. 110° in the micro m.-p. app., but if the sublimation takes place without cooling the vapors (by a piece of wet paper on the cover glass), the crystals obtained m. 126°. By dissolving the lower-melting product and recrystg., the substance with the higher m. p. is obtained. The 2 forms of crystals are also distinguishable in the polarization microscope. W. T. H.

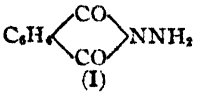
A relation between rotenone, deguelin and tephrosin. E. P. CLARK. *Science* **73**, 178(1931); cf. *C. A.* **24**, 2752; **25**, 1252.—The evidence shows that these substances, which together with toxicarol are the principal toxic constituents of derris and "cube" roots, are closely related chemically. Rotenone upon mild oxidation yields dehydrorotenone, $C_{23}H_{20}O_6$. This compd. when boiled with alc. KOH and Zn dust forms HO acid, $C_{23}H_{24}O_8$, which when oxidized with H_2O_2 yields derric acid, $C_{12}H_{14}O_7$. Deguelin, $C_{23}H_{22}O_6$, when oxidized with $K_3Fe(CN)_6$ gives dehydrodeguelin, $C_{23}H_{20}O_6$, which is analogous to dehydrorotenone. On boiling with alc. KOH dehydrodeguelin yields deguelic acid, $C_{23}H_{24}O_8$, which when oxidized with H_2O_2 also yields derric acid. Tephrosin, $C_{23}H_{22}O_7$, when treated with a mixt. of H_2SO_4 and AcOH forms dehydro-

deguelin. Derric acid thus constitutes one-half of the mol. of rotenone, deguelin and tephrosin. LAWRENCE P. MILLER

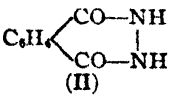
Rotenone, the effective constituent of derris root. VIII. The chemical constitution of derric acid and risic acid. SANKICHI TAKEI, SHIKIRO MIYAJIMA AND MINORU ONO. *Bull Inst. Phys. Chem. Research* (Tokyo) **9**, 1016–22(1930); *Abstracts* 95–9(in German) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, Nos. 278–81); cf. *C. A.* **24**, 4037.—Rotenone (20 g.) and 50 g. anhyd. AcONa in 500 cc. EtOH, treated with 16 g. I_2 in 130 cc. EtOH in 1.5 hrs., followed by boiling for an hr. and filtering off the AcONa, give 14 g. of *dehydrorotenone* (I), m. 216°; 4.3 g. more is obtained from the EtOH filtrate. No Ac deriv. of rotenolone occurs. I (20 g.) in 300 cc. EtOH and 7 g. KOH in 7 cc. H_2O give 16 g. of *derrisic acid*, $C_{21}H_{18}O_6(OMe)_2$ (II), m. 153°, which with $NH_2OH.HCl$ and AcONa gives 80% of *derrisic acid oxime*, $C_{23}H_{24}O_7$:NOH, m. 142°. It gives with $FeCl_3$ the purple color, proving the presence of a phenolic OH radical. Ten g. II in 200 cc. KOH (1%) with 75 g. $KMnO_4$ in 700 cc. H_2O gives 2.6 g. of *risic acid*, 2,5-$(MeO)_2C_6H_3C(OH)(CO_2H)_2$ (III), m. 225°, which is not changed by H_2O_2 oxidation in alk. soln., but entirely decompd. by prolonged heating with $KMnO_4$. III, methylated with CH_2N_2, gives quant. its *di-Me ester*, $C_8H_4O_2(OMe)_4$, colorless, m. 86°, insol. in $NaHCO_3$ but sol. in NaOH; with alkali it is converted into III. Three g. III, heated for 7 mins. at 255–60°, gives 1.3 g. of *decarboxyrisic acid*, $C_8H_6O_2(OMe)_2$ (IV), m. 116°, crystals from H_2O, m. 68–98° but m. 116° when the water of crystn. is lost. The oxidation of III and IV with *N* HNO_3 results in *dimethoxybenzoic acid* (V), yellow, m. 209°, which with CH_2N_2 is converted quant. into the *Me ester*, $C_{10}H_{11}O_6N$, faint yellow, m. 146°, being hydrolyzed by heating for 30 mins. with dil. NH_3-KOH to the original acid. The mixt. of 5 g. III and 20 g. KOH, moistened with a small portion of H_2O, heated for 3 hrs. at 270–300°, gives 0.01 g. of $C_6H_6O_2$, m. 167–8°, whose mixt. with hydroquinone m. 168–9°. It reduces vigorously Fehling soln. and the NH_3-$AgNO_3$. One g. III with 5 g. $KMnO_4$ gives 0.1 g. of *derric acid*, 2,5-$(MeO)_2$-$C_6H_3C(OH)(CO_2H)CH_2CO_2H$ (VI), colorless, m. 171°, which, on fusion, does not liberate CO_2 and is oxidized to III. Regarding the optical isomers of VI and III, another paper will follow. K. KONDA

Condensation products from aryldithioglycolic acids. ERICH GEBAUER-FÜLNEGG AND HELENE JARSCH. *Monatsh.* **56**, 317-21(1930).—Brief details are given of dyes obtained by heating the following compds. with $ClSO_3H$ at 50–60° for 2 hrs.: benzene-1,2-, 1,3- (I) and 1,4-dithioglycolic acids, the 4-Cl and 2,5-Cl_2 derivs. of I and 1,4-benzoquinone-2,3- and 2,5(2,6?)-dithioglycolic acids. The dyes are probably bisthionaphtheneindigo-*x*,*x*'-dithioglycolic acids. They are violet compds. which dye wool from acid baths blue-green tones. C. J. WEST

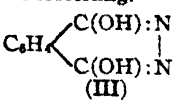
Synthesis of phenol ketones according to Hoesch. IV. W. BORSCHE AND K. DIACONT. *Ber.* **63B**, 2740–3(1930); cf. *C. A.* **24**, 95.—It was shown in Papers I and II that arylglyoxylic nitriles with multivalent phenols under the conditions of the Hoesch synthesis do not give hydroxylated benzils but lactone imines or ketones of polyhydroxytriphenylacetic acids; thus, PhCOCN and *m*-$C_6H_4(OH)_2$ (I) give the lactone, $HOC_6H_3.CPh[C_6H_3(OH)_2].CO.O$ (II). This reaction seems, however, to be limited to the arylglyoxylic nitriles and to depend on the linking of an aromatic acid radical with CN or CO, for on the one hand II has also been obtained (WITH NIEMANN) from $PhCOCO_2H$ and I in Et_2O with $ZnCl_2$-HCl, and on the other hand, the alkylglyoxylic nitriles thus far tested (MeCOCN and EtCOCN) give with I under the conditions of the Hoesch synthesis only the monoketimines of the diketones 2,4-$(HO)_2C_6H_3CO$-COR. Phloroglucinol unexpectedly reacts much less readily and the products have such unpromising properties that nothing definite can as yet be said as to their compn. and structure. *1-(2,4-Dihydroxyphenyl)propane-1,2-dione*, yellowish, m. 159°; *disemicarbazone*, yellowish, m. 243–5°; *bis(2,4-dinitrophenylhydrazone)*, red, m. 249–50°. *2-(2,4-Dihydroxyphenyl)butane-1,2-dione*, yellowish, m. 150° (the intermediate *monoketimine-HCl* forms brownish crystals); *disemicarbazone*, m. 205°; *bis(2,4-dinitrophenylhydrazone)*, red, m. 245°. C. A. R.



The condensation of catechol tannin. MAX BERGMANN AND GEORGI POJARLIEFF. *Naturwissenschaften* **18**, 1114(1930).—The condensation tendency of catechol is due to its structure of hydroxydihydropyran and by the simultaneous presence of a 2,3-double bond in the pyran ring with a hydroxyl in position 5. Tetramethylcatechol, with all phenol groups methylated, still is easily condensable (unpublished result). The benzene rings are not essential for the condensation, since glucal (Bergmann and Freudenberg, *C. A.* **24**, 1352–3) is condensed in a similar manner by acids; dihydroglucal (a tetrahydropyran) is, however, acid-resistant (Fischer, *C. A.* **8**, 1121). Not all HO groups



can be removed from catechol without destroying the condensability; anhydroacetobutyl alc. does not condense. B. J. C. VAN DER HOEVEN



The chemistry of quinic acid. KARL JOSEPHSON. *Svensk. Farm. Tids.* **34**, 649–54(1930).—A critical review on the constitution of $C_6H_7(OH)_4CO_2H$. A. R. R.

Preparation of 4-nitrophthalimide and derivatives. LEOPOLD F. LEVY AND HENRY STEPHEN. *J. Chem. Soc.* **1931**, 79–82.—Nitration of 20 g. $C_6H_4(CO)_2NH$, by adding it gradually to 24 cc. HNO_3 (d. 1.44) and 200 cc. H_2SO_4 (10% SO_3) and holding the mixt. at 80° for 30 min., then cooling and pouring into 400 g. ice, keeping the temp. below 20°, gives 78% of the 4-NO_2 deriv., m. 198°; use of ordinary concd. H_2SO_4 reduces the yield to 40%. Reduction of 20 g. of the NO_2 deriv. with 84 g. $SnCl_2$ and 450 cc. HCl and 450 cc. H_2O gives 15.3 g. of the 4-NH_2 deriv., m. 294°; *Ac deriv.*, pale straw, m. 331° (cor., decompn.); *Bz deriv.*, cream colored, m. 322° (cor., decompn.); $C_6H_4(CO)_2O$ at 180° for 1 hr. gives *4-phthalimidophthalimide*, yellow, m. 319° (cor., decompn.). The diazo compd. couples with PhOH and α- and β-$C_{10}H_7OH$, giving orange, maroon and light brown dyes, resp., and with $PhNH_2$ and α- and β-$C_{10}H_7NH_2$ in acid soln., giving deep red, red and yellow dyes, resp. With CuCl in HCl the diazo compd. gives the 4-Cl deriv., m. 210°; heating the diazo compd. gives the 4-HO deriv., m. 290°. C. J. WEST

The action of hydrazine acetate on 3-nitrophthalic anhydride. M. MIHAILESCU AND L. PROTOPOPESCU. *Bul. soc. chim. Romania* **12**, 95–102(1930).—M. and H. reply to the objections of Radulescu and Georgescu (cf. *C. A.* **20**, 184) to the formula (I) which Mihailescu and Florescu (cf. *C. A.* **18**, 3183) propose for the product of reaction of $N_2H_4.2AcOH$ on $C_6H_4(CO)_2O$ rather than the formula (II) of Forsterling.

(I)

(II)

(III)

M. and H. cite the following properties of this compd. which are not consistent with formula II and its enol (III) but are consistent with formula I and its hydrolysis product $HO_2CC_6H_4CONHNH_2$ (IV). (*1*) The substance is difficultly sol. in water but is hydrolyzed by water to give an acid reaction to litmus. (*2*) It dissolves completely in alkali hydroxides with red color and is pptd. unchanged by acids. (*3*) It dissolves in carbonates and bicarbonates with effervesence but it is not pptd. by an excess of CO_2 as R. and G. erroneously state (*4*) Only monometallic salts are formed. (*5*) Three properties indicate that the substance possesses an NH_2 group: (*a*) It is decompd. by HNO_2 and NaBrO; (*b*) it reacts with aromatic aldehydes to give condensation products; (*c*) its Ac and Me derivs. have properties more like those of *N*- than of *C*-derivs. Ten g. of 3-nitrophthalic anhydride in 150 cc. boiling glacial AcOH reacts with 15 g. $N_2H_4.H_2SO_4$ and 18 g. cryst. AcONa in H_2O to form $NO_2C_6H_4(CO)_2NNH_2$ (V). V does not m. 300°; NaBrO decomps. it; only mono-Ac derivs. are formed by Ac_2O and AcCl; alkali hydroxides, carbonates and bicarbonates dissolve it, producing a red coloration and needle-shaped, golden yellow crystals of only monometallic derivs. which do not m. 300° but above this temp. decomp. with explosion. Ac_2O reacts with V to form the mono-Ac deriv. as needles resembling cotton wool which m. 230°. V reacts with BzCl in hot pyridine to form a mono-Bz deriv. as a sandy powder m. 260°. V in hot NH_4OH reacts with $AgNO_3$ to form a deep yellow Ag salt which is a monometallic salt as indicated from N detns. Ag could not be detd. as explosions resulted in the attempts. The Ba salt of V was prepd. by decompn. of the K salt of V with $BaCl_2$ as yellow needles which analysis showed to be a monometallic salt. V reacts with Me_2SO_4 at 120° to form plates of a mono-Me deriv. m. 265°. H ating V with anisaldehyde and fused AcONa gives needles of $NO_2C_6H_4(CO)_2NN{:}CHC_6H_4OMe$ (VI) which m. 280° aud react with KOH soln. to form $MeOC_6H_4CHO$ and the K salt of V. These properties of V together with the arguments in regard to the structure of I (an analogous compd.) justify the structure assigned to V. ODEN E. SHEPPARD

Menthone series. IX. New optical resolution of *dl*-menthol and of *dl*-camphor-10-sulfonic acid. JOHN READ AND WM. J. GRUBB. *J. Chem. Soc.* **1931**, 188–95; cf. *C. A.* **25**, 1233.—Although the naturally occurring form, *l*-menthol (I), was fairly readily obtained by the optical resolution of the *dl*-form (II) by Pickard and Littlebury (*C. A.* **6**, 1284), the method does not appear to lend itself to the prepn. of *d*-menthol (III) in quantity. I and *d*-camphor-10-sulfonyl chloride (IV) in quinoline or pyridin give 85% of *l-menthyl d-camphor-10-sulfonate* (V), m. 125.5°, crystallizes from light petroleum in slender needles, 5–6 cm. long, from AcOEt in doubly-terminated prisms; the system is tetragonal, $c:a = 1.3788:1$, *a*(100), *m*(110), *p*(111); $[\alpha]_D^{18}$ —20.9° ($CHCl_3$,

c 1.9855). At 153°, V decomps. to *d*-camphor-10-sulfonic acid (VI) and partly racemized *d*-Δ^3-menthene (VII). When steam-distd., V undergoes extremely slow decompn., giving I, VI and VII. V is very stable toward hot EtOH-KOH; Na in hot EtOH gives I and VII. Prolonged boiling with 20% HCl or H_2SO_4 causes a gradual decompn. of the ester; the most satisfactory hydrolyzing agent is hot 50% $(CO_2H)_2$ the products being I, VI and VII. *l-Menthyl l-camphor-10-sulfonate* (VIII), m. 47°, $[\alpha]_D^{16}$ —77.6° ($CHCl_3$, *c* 1.9950); at 153° it decomps. into *l*-camphor-10-sulfonic acid and VII. It is somewhat less resistant to hydrolysis than is V. II and IV in quinoline give an ester with $[\alpha]_D^{15}$ 26.0° ($CHCl_3$, *c* 1.9); 2 crystns. from light petroleum and 2 from AcOEt give 45% of V; decompn. with 50% $(CO_2H)_2$ gives only 10% of pure I. II and *l*-camphor-10-sulfonyl chloride give 42% of *d-menthyl l-camphor-10-sulfonate* (IX), m. 125.5°, $[\alpha]_D^{15}$ 20.8° ($CHCl_3$, *c* 2.0740); decompn. with 50% $(CO_2H)_2$ gives 10% pure III. An equimol. mixt of VIII and IX melted indefinitely over a wide range of temp., and gave no indication of the formation of a partial racemate. Similar behavior was shown by a mixt. of IV and VIII. In both cases, the observed rotatory power in $CHCl_3$ was practically equal to the mean value of the 2 components. An equimol. mixt. of IV and IX appears to give mixed crystals when allowed to sep. slowly from AcOEt. Details are given of the resolution of *dl*-camphor-10-sulfonic acid with l.

C. J. West

Action of Beckmann's mixture on some monocyclic terpenes. II. Terpinolene and "origanene." Thomas A. Henry and Humphrey Paget *J. Chem. Soc.* **1931**, 25–32; cf. *C. A.* **22**, 1346.—Terpinolene (I) was prepd. by shaking *dl*-α-pinene with half its vol. of EtOH-H_2SO_4 (50% by wt.) and also from terpineol by boiling gently with 40% aq. $(CO_2H)_2$ for 30 min. or by keeping it at room temp. for 2–3 days with EtOH H_2SO_4. I was purified through the tetrabromide, which crystallizes in 2 forms; from 2 vols. EtOH, Me_2CO or AcOEt, m. 122°, monoclinic, $a:b:c$ = 0.7804:1:0.9668, β 114° 15′ (cf. Hintze, *Z. Kryst* **10**, 258(1885)), from 10 vols. Me_2CO, monoclinic, rectangular plates, m. 119°, $a:b:c$ = 2.5995:1:2.0333, β 118° 8.5′, $a(100)$, $m(110)$, $c(001)$, $p(101)$. The regenerated I b_{10} 121°, b_{764} 186°, d_{15}^{15} 0.8632, n_D^{26} 1.4886, the same product is obtained from the 2 tetrabromides and on bromination yields 86.8% of the first tetrabromide. I is not very readily attacked by Beckmann's mixt. The principal products of oxidation are levulic acid and AcOH. A small amt of an unsatd. keto lactone is obtained, which is regarded as *β-thujaketo-lactone* (*ε-keto-β-hydroxyisopropyl Δα-heptenolactone*) (II), $C_{10}H_{14}O_3$, m 48–50°; *semicarbazone*, m. 222.3° (cor., decompn.), reduction of II gives homoterpenyl Me ketone. Hydrolysis with warm alkali gives the *acid* $AcCH_2CH_2C(CMe:CH_2):CHCO_2H$, m 130°, which absorbs 4 H, giving *dl* ε-keto-β-isopropylheptoic acid. II is not readily attacked by Beckmann's mixt. but at 60° after 2 days there results terebilic acid in quant. yield. "Origanene" (Pickles, *C. A.* **2**, 2248, 2673) is generally regarded as α-terpinene; this suggestion ignores the fact that origanene yields a nitrosyl chloride, m. 91–4°, a nitrolpiperidide, m. 198°, and a nitrolbenzylamine, m. 104–5°, which have not been obtained from α-terpinene. Reëxamn of residues from the prepn. of carvacrol from *Cyprus origanum* oil shows that α-terpinene is present, but there is also about 1.4% of a terpene giving the above cryst. derivs. and for which the name origanene is again proposed until the constitution can be established.

C. J. West

Pinene and nopinene. Georges Brus. *Bull. Inst. pin* **1929**, 271–6, 293–300; **1930**, 7–16, 33–8, 63–8, 87–96, 109–12, 131–6, 151–4, 175–8, 199–205, 225–8, 244–7, 270–4; cf. *C. A* **17**, 3176, **19**, 487, 2653; **22**, 1347, 3157; **23**, 829.—After reviewing the origin and phys. and chem. properties of *d*- and *l*-pinene and *d*- and *l*-nopinene, a more detailed account is given of the previously published investigations.

A. P.-C.

Production of camphor. Willibald Rehdern. *Riechstoffind.* **5**, 105–8(1930).—The present and past methods for the distn. of camphor-producing material are described.

W. O. B.

Photopolymerization of piperitone. W. Treibs. *Ber.* **63B**, 2738–40(1930).—Piperitone (I) in aq. AcOH or alc. exposed to the light of a quartz Hg lamp begins after several hrs. (depending on the diam. of the containing quartz vessels) to deposit needles which are repeatedly filtered off until no more are formed; they are followed by the sepn. of a yellow oil. This oil, when dissolved in hot alc., gives more of the needles on cooling. The yield of cryst. product is the same whether the soln. is illuminated in an air or H atm., and small quantities of uranyl acetate have but a slight influence if the deposits formed on the walls of the vessel are removed; larger quantities, through their screening action, slow up the reaction. The needles seemed to be quite homogeneous, b. about 365° almost without decompn. and m. 112°, but by re-

peated crystn. from MeOH they were sepd. into 3 fractions having the compn. and mol. wt. (Rast) of a *dimeric piperitone:* (1) needles, m. 162°, form no semicarbazone; (2) silky needles, m. 142–4°, yielding a *semicarbazone*, $C_{20}H_{32}O_2N_6$, m. 228–35° (decompn.) depending on the rate of heating, that sepd. in 2 forms (needles and cubes) which did not depress each other's m. p.; (3) rhombic leaflets, m. 157–9°. (1) and (3) greatly depressed the m. p. of each other. The semicarbazone of (2) regenerates (2) with hot concd. aq. $(CO_2H)_2$. The dimerization in this case evidently has occurred through the double bond in I, probably with formation of a 4-membered ring, but the non-formation of a semicarbazone by (1) and (3) does not necessarily prove that the C:O group is involved in the formation of these dimers, for steric influences may prevent the formation of a semicarbazone even though the C:O group is still intact. In sunlight instead of the light of the Hg lamp, I yields only the dimer (1). Preliminary expts. indicate that carvone which, according to Ciamician and Silber, yields only 1 dimer in sunlight, also forms 2 dimers when exposed to the light of a Hg lamp.

C. A. R.

Correction [autoxidation of cedrene]. A. Blumann *Ber.* **63B**, 2680(1930); cf. *C. A.* **24**, 97. –The unsatd. terpene $C_{15}H_{22}$ (obtained by dehydration of the alc. resulting from the oxidation of cedrene with O and a Co siccative) was described as having $[\alpha]_D$ –125° when, as a matter of fact, it is *d*-rotatory. The prepn. used at the time was insufficiently purified and final values on the consts. of the compd. will be published shortly.

C. A. R.

Fokienol, a new monocyclic sesquiterpene alcohol. L. S. Glichitch. *Compt. rend.* **191**, 1457–60(1930). Distn. of stems of *Fokienia hodginii* gives an oil which is mostly a tertiary monocyclic alc., $C_{15}H_{26}O$, b_2 125.6°, d_{24} 0.9236, $n_D^{22.5}$ 1.4975, α_D 18°35′, mol. refraction 70.18, indicating 2 double bonds. Distn. causes ring closing and the compd. must be isolated through its formate. Acids cause dehydration to a bicyclic diene, $C_{15}H_{24}$, isofokienene. HPO_3 gives the monocyclic fokienene, b_7 112–4°, d_{16} 0.8802, α_{Di} +16°56′, n_D^{13} 1.49594. All 3 on dehydrogenation with S give 1,6,4-$C_6H_3Me_2CHMe_2$.

V. F. Harrington

Heteropolar carbon compounds. XII. New dyestuffs of the aniline blue series and perchlorates of several important triphenylmethane dyes. W. Dilthey and R. Dinklage. *J. prakt. Chem.* **129**, 24–30(1931); cf. *C. A.* **24**, 1855. –Parafuchsin base and *p* $H_2NC_6H_4Ph$, heated with BzOH 6 hrs. at 175–80°, give *tri(4-phenyl)aniline blue*, $(PhC_6H_3NHC_6H_4)_3CCl$, golden glistening crystals with a violet-blue basic color, decompg. about 225°; drying at 110° causes no noticeable decompn. Fuchsin base and *p* $H_2NC_6H_4OPh$ in the same way give *tri(4-phenoxy)aniline blue*, $(PhOC_6H_4NHC_6H_4)_3CCl$, violet, decomps. about 230°. *p* $H_2NC_6H_4SPh$ and parafuchsin base give *tri(4-phenthiol)aniline blue*, $(PhSC_6H_4HNC_6H_4)_3CCl$, blue or violet, decomps. 220–30°. Colors are given for the EtOH, H_2O and H_2SO_4 solns. Little difference is observed in the color of the 3 new dyes. The m. ps. for the following perchlorates are approx.: *Benzaldehyde green*, blue-green, 200°; *brilliant green*, blue-green, 183°; *rhodamin 3B*, red, 167°; *crystal violet*, violet, 239–40°, *methylene blue*, dark blue, 231–2°; *Victoria blue*, blue, in a bath at 320°, decomps. violently; *pararosaniline*, dark red, 317° (block).

C. J. West

Conjugated double bonds. XIV. Addition of maleic acid anhydride to polyenes. Richard Kuhn and Theodor Wagner-Jauregg. *Ber.* **63B**, 2662–79(1930); cf. *C. A.* **25**, 683. –The addn. of maleic anhydride (I) to dienes has often been used in the study of the structure of natural products such as cholesterol and muscarufin, and it seemed of theoretical and practical importance to det. whether the reaction could be extended to compds. with a large no. of conjugated double bonds such as the dyes of the bixin and carotene series. Preliminary expts. showed that all the polyene dyes tested are decolorized by I and an addn. product of Me bixin was isolated as a well-crystd. Na salt. Because of the no. of isomers possible, however, the structure of this product could not for the time being be established and it was to shed light on this question that the present study of the behavior of a series of synthetic diphenylpolyenes toward I was undertaken. Stilbene, although it has only 1 double bond, reacts very readily with I in hot xylene, forming an amorphous, approx. 1:1 addn. product of high mol. wt.; it is presumably cyclic and is to be described in detail elsewhere. $(PhCH:CH)_2$ takes up 1 mol. I, as has also since been found by Diels and Adler (*C. A.* **24**, 96) but the addn. products vary with the conditions of prepn. In xylene are obtained rhombs m. 198° to 203° from prepn. to prepn., which can be sepd., without change in the compn., $C_{20}H_{16}O_3$, into fractions differing in m. p. by at most 4° and which are probably mixts. of isomers. D. and A. carried out the addn. in a molten mixt. of the components and

obtained a compd. m. 207° (apparently uncor.). An isomer m. 212.5–4.5° (cor.) was obtained by rearrangement of the above mixt. with Cl_3CHCO_2H in $CHCl_3$, but its m. p. fell to 196–8° (cor.) on crystn. from C_6H_6. That the I has added at the 1,4-positions in every case is shown by the conversion of the addn. products into terphenyl by hydrolysis and oxidation with $K_3Fe(CN)_6$. The isomers probably differ in the position of the double bond. The isomer m. 198° with hot aq. NaOH gives a *3,6-diphenyltetrahydrophthalic acid* (II), rhombs with 1 H_2O from alc., which when heated loses H_2O and shows the high m. p. of D. and A.'s anhydride. An oily isomer (III) of II is obtained through the *dichloride*, m. 143–4° (cor.), from $(PhCH:CH)_2$ and fumaryl chloride. With HCl in Et_2O III changes into crystals, m. 230–1° (cor.). From its method of prepn., III contains the CO_2H groups in the *trans*-position. Assuming that the double bond occupies the same position in II and III, *cis-trans* isomerism can be explained only if the double bond is in the 3,4- or 4,5-position. The low-melting anhydride of II decomps. to a large extent, when distd. under 12–5 mm., into $(PhCH:CH)_2$ and I. $(PhCH:CHCH:)_2$ with I yields an addn. product $C_{22}H_{18}O_3$ (IV), m. 199.5–200° (cor.), confirming the observation of D. and A. That addn. takes place at the 1,6-positions is shown by simultaneous decarboxylation and dehydrogenation by distn. with anhyd. $Ba(OH)_2$ and Se, which yields *1-phenyl-2-biphenylylethylene* (V), m. 221–2° (cor.), identical with the product obtained by distn. of *p*-$PhC_6H_4COCH_2Ph$ with Zn dust in H. $(PhCH:CHCH:CH)_2$ likewise adds 1 mol. I in boiling xylene but the product (VI) is not identical with the *3-phenyl-6-styryltetrahydrophthalic anhydride*, (IV) above. It m. 192–3° (cor.) and is also obtained by distn. of IV *in vacuo;* it is probably also a 3-phenyl-6-styryltetrahydrophthalic anhydride, for with O_3 it yields BzOH in abundance, and hydrolysis gives an acid which, when dehydrogenated with $K_3Fe(CN)_6$ and decarboxylated or when distd. directly with soda lime, changes into V. The isomerism of IV and VI is probably due to a difference in the position of the double bond in the cyclohexene ring. On hydrolysis VI gives an *acid* m. 190–1° (cor.) with regeneration of VI. $(PhCH:CHCH:CH)_2$ adds 2 mols. I when the mixt. of the components is cautiously fused, forming *6,6'-bis(3-phenylcyclohexene-1,2-dicarboxylic anhydride)* (VII), m. 275° (cor., decompn.), and in boiling xylene is obtained an *isomer* (VIII), m. 264° (decompn.), along with VII. Crystn. from $(Cl_2CHCO)_2O$ raises the m. p. of VIII to 292° (decompn.) which again falls to 264° on crystn. from Ac_2O or *o*-$C_6H_4Cl_2$. On hydrolysis, dehydrogenation with $K_3Fe(CN)_6$ and distn. with soda lime, VIII gives $(p\text{-}PhC_6H_4)_2$, m. 313–4° (cor.); attempts to effect the degradation by direct distn. with soda lime gave a hydrocarbon, $C_{24}H_{18}$, m. 281–2°, whose structure has not been established. Hydrolysis of VIII with concd. NaOH gives an amorphous *dicarboxylic acid*, easily sol. in cold HCO_2H and soon sepg. in crystals, probably as the result of isomerization; the same change was observed when the amorphous acid was warmed in Et_2O with a few drops of HCO_2H. The isomer seps. from dil. alc. with 2 mols. H_2O and when heated to 140° in Cl_2CHCO_2H and pptd. with Et_2O it gives the anhydride m. 290° (see above). Attempts to condense $(PhCH:CHCH:CH)_2$ with only 1 mol. I gave always VII and the unchanged hydrocarbon. Toward fumaryl chloride the tetraene behaves as with I; the resulting *tetracarboxylyl chloride* m. 231.5–2.5° (cor.). $(PhCH:CHCH:CHCH:)_2$ in boiling xylene adds chiefly 2 mols. I; there are obtained 2 *isomers*, $C_{30}H_{24}O_6$, sepd. by fractional crystn. from Ac_2O into the more sol. chief product, m. 235.5°, and a less sol. isomer, m. 255.5° (both cor., decompn.). There is also formed an amorphous substance (apparently a 1:3 product), decomps. 276.5° (cor.). The 235.5° compd. is apparently formed by 1,4- and 7,10-addn.; dehydrogenation and decarboxylation gives a compd. m. 302–3°, apparently identical with a product obtained by dehydrogenation of $(p\text{-}PhC_6H_4CH_2)_2$ and assumed to be *di-p-biphenylylethylene*. $(PhCH:CHCH:CHCH:CH)_2$ reacts readily with I in boiling tetralin, forming a product difficultly sol. even in boiling Ac_2O, dioxane, $PhNO_2$ and BzOEt. Apparently 3 mols. I are in the main added. Simultaneous dehydrogenation and decarboxylation gives a hydrocarbon, begins to m. 320°, having the compn. of a *quinquiphenyl*. $(PhCH:CHCH:CHCH:CHCH:)_2$ behaves like the hexaene, yielding a difficultly sol. product which has not yet been obtained in homogeneous form. These results show that when a large no. of conjugated double bonds are present they each add 1 mol. I with formation of 6-membered rings. The reactive diene groups in the diphenylpolyenes are at the ends of the chains and the behavior of these compds. toward I is to be ascribed to the same cause as their behavior toward H in the formation of dibenzylpolyenes, *viz.*, the greater reactivity of the end methine groups adjacent to the Ph residues.

C. A. R.

2-Methylnaphthalenes. III. K. Dziewoński and A. Wulffsohn. *Bull. intern. acad. polonaise* **1929A**, 143–8.—Sulfonation of 2-$C_{10}H_7Me$ with an equimol. quantity

of $ClSO_3H$ in $PhNO_2$ at 30–40° gave *2-methylnaphthalene-8-sulfonic acid* (*Na salt; chloride*, m. 94–6°; *amide*, m. 172–4°; *anilide*, m. 162–4°). Its constitution was established by conversion into 7-methyl-α-naphthol, m. 109–11° (*acetate*, m. 39–41°; *azo deriv.* with *p*-nitroaniline, m. 250° (decompn.)), by fusion of the Na salt with KOH. B. C. A.

1, 4-Dibenzylnaphthalene and its corresponding keto derivatives. K. Dziewoński, J. Moszew, S. Lepiankewicz and L. Sucheri. *Bull. intern. acad. polonaise* **1929A**, 650–7.—The dibenzylnaphthalene, m. 88°, obtained as one of the products of the action of $PhCH_2Cl$ on $C_{10}H_8$ in presence of $AlCl_3$ or fused $ZnCl_2$ ("β-dibenzylnaphthalene" of Dziewoński and Moszew, *C. A.* **23**, 3220, 3923) is now shown to be *1,4-dibenzylnaphthalene* (picrate, m. 107°), also prepd. by the reduction of *4-benzoyl-1-benzylnaphthalene*, m. 113° (*phenylhydrazone*, m. 155–6°; *oxime*, m. 202–3°). The latter is obtained by the interaction of $1\text{-}C_{10}H_7CH_2Ph$ and BzCl in presence of fused $ZnCl_2$. The orientation of both compds. is established by their oxidation with HNO_3 to the known $1,4\text{-}C_{10}H_6Bz_2$, m. 106° (Scholl and Neumann, *C. A.* **16**, 2143) (*dioxime*, m. 261°). Treatment of $1,4\text{-}C_{10}H_6(CH_2Ph)_2$ with $ClSO_3H$ at the ordinary temp. affords *1,4-dibenzylnaphthalenesulfonic acid*, isolated as the Na salt. Nitration of $4,1\text{-}C_{10}H_6BzCH_2Ph$ yields a *mononitro deriv.*, m. 172–3°. A by-product of the reduction of the same compd. is *1,4-dibenzyltetrahydronaphthalene*, m. 92–3°. B. C. A.

***peri*-Benzoyl and -benzyl derivatives of naphthalene.** K. Dziewoński, J. Auerbach and J. Moszew. *Bull. intern. acad. polonaise* **1929A**, 658–63.—*1-Benzoyl-8-benzylnaphthalene*, m. 142° (*oxime*, m. 220–2°), is prepd. by the action of $PhCH_2Cl$ on $1\text{-}C_{10}H_7Bz$ in the presence of $AlCl_3$ at 160–70°. Oxidation of this with HNO_3 yields *1,8-*$C_{10}H_6Bz_2$ (*bisphenylhydrazone*, m. 270–1°; *dioxime*, m. 270°) (cf. *C. A.* **23**, 3220, 3923). B. C. A.

Synthesis of acetyl derivatives of 1-benzylnaphthalene. I. 4-Acetyl-1-benzylnaphthalene. K. Dziewoński and J. Moszew. *Bull. intern. acad. polonaise* **1930A**, 66–71.—$1\text{-}C_{10}H_7CH_2Ph$ reacts with AcCl in the presence of $AlCl_3$ in CS_2 at the ordinary temp. to give *4-acetyl-1-benzylnaphthalene*, b_{12} 240–5°, m. 75° (*picrate*, m. 113°) (60%), together with a *di-Ac deriv.*, b_{12} 265–70°, m. 135° (10%), as a by-product. The *oxime*, m. 240–1°, of $1,4\text{-}C_{10}H_6(CH_2Ph)Ac$ undergoes a Beckmann rearrangement when its soln. in AcOH and Ac_2O satd. with anhyd. HCl is heated at 100°, to give *4-acetamido-1-benzylnaphthalene*, m. 208–9°, hydrolyzed by boiling 6% HCl to $4,1\text{-}C_{10}H_6(CH_2Ph)NH_2$ identical with a specimen obtained by the action of NH_3 on $4,1\text{-}C_{10}H_6(CH_2Ph)OH$. (*C. A.* **22**, 2164). HNO_3 (d. 1.52) in AcOH at 10–15° converts $1,4\text{-}C_{10}H_6(CH_2Ph)Ac$ into its *5-nitro-deriv.*, m. 153°, while boiling 10% HNO_3 oxidizes it to *4-benzoyl-α-naphthoic acid*, m. 180–1°. B. C. A.

Bromination of 4-nitro-1-methylnaphthalene. John S. H. Davies and Albert E. Oxford. *J. Chem. Soc.* **1931**, 220–1.—$4,1\text{-}O_2NC_{10}H_6Me$ and Br in a quartz flask in ultra-violet light give a *mono-Br deriv.*, yellow, m. 137.5–8.5°, and a very small quantity of a *tetra-Br deriv.*, m. 189–90° (decompn.); the same mixt. was obtained in a sealed tube at 100–20° for 2 hrs. $\alpha\text{-}C_{10}H_7CH_2Cl$, b_{14-16} 146–58°, seps. from EtOH at −15° as silvery flakes, m. 29.5–30.5°; this was previously described as a liquid. $2,4\text{-}(O_2N)_2C_6H_3CH_2Cl$ and NaBr in MeOH, boiled 6 hrs., give the *bromide*, m. 46–7°. C. J. West

Naphthalene series. II. Diaryl- and triarylmethane derivatives of dimethyl-α-naphthylamine. Basker Gokhle and Frederick A. Mason. *J. Chem. Soc.* **1931**, 118–26; cf. *C. A.* **24**, 5296.—$(Me_2NC_{10}H_6)_2CH_2$, m. 181–2.5°, was obtained from $\alpha\text{-}C_{10}H_7NMe_2$ and HCHO in AcOH-HCl and methylal in AcOH-HCl or H_2SO_4; the base was surprisingly resistant to oxidizing agents; chloranil in glacial AcOH at 110° gives 2% of *4,4'-tetramethyldiamino-1,1'-dinaphthylcarbinol*, m. 184–6°; cold AcOH gives a faintly green soln., becoming blue-violet on warming; concd. HCl or H_2SO_4 gives a deep yellow soln. *4-Dimethylamino-1-naphthoyl chloride* and *anilide* were prepd. from the acid. Attempts to prep. the ketone $(Me_2NC_{10}H_6)_2CO$ from this chloride and $\alpha\text{-}C_{10}H_7NMe_2$ in $C_2H_2Cl_4$ gave only tarry products. *4,4',4"-Hexamethyltriaminotrinaphthylmethane*, m. 266–7.5°, is formed from $\alpha\text{-}C_{10}H_7NMe_2$ and $HC(OEt)_3$ with $AlCl_3$ at 70°. $Me_2NC_{10}H_6COCl$ and $PhNMe_2$ with $AlCl_3$ in $C_2H_2Cl_4$ give *4,4'-tetramethyldiaminophenyl-1-naphthyl ketone*, m. 128.5–9°; Et_2O, EtOH and dil. mineral acids give light greenish yellow solns. With $POCl_3$ the ketone condenses with $PhNMe_2$, yielding a deep blue dye, probably identical with "Naphthoblau." Reduction with Na-Hg in EtOH gives the corresponding *carbinol*, pale yellow, m. 62–3°; the AcOH soln. is a brilliant blue. $4\text{-}H_2NC_{10}H_6NMe_2$; obtained by reduction of the 4-NO deriv., yields an *Ac deriv.*, m. 185°. Attempts to prep. the analog of methylene-blue B failed. Ab-

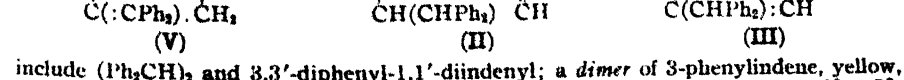
sorption curves of the carbinols in AcOH are given; values calcd. according to Moir's theory agree with the observed maxima. C. J. WEST

Naphthalene-1,5-disulfonic acid as a by-product in the monosulfonation of naphthalene. CEDRIC B. RADCLIFFE AND WALLACE F. SHORT. *J. Chem. Soc.* **1931**, 220.—In the prepn. of 1-$C_{10}H_7CN$ from $C_{10}H_7SO_3Na$ and KCN, there is obtained 1.4 g. 1,5-$C_{10}H_6(CN)_2$ from 100 g. $C_{10}H_8$ employed in the sulfonation; because of the sparing soly. of $C_{10}H_6(SO_3H)_2$ as the Ba salt and the incomplete conversion into the dicyanide, this est. of the degree of disulfonation is a conservative one. C. J. WEST

Theory of halogen substitution. II. PAUL PFEIFFER AND PAUL SCHNEIDER. *J. prakt. Chem.* **129**, 129-44(1931); cf. *C. A.* **24**, 1858.—Previous work showed that certain ethylenes give colored bromides. In order to study the constitution of these the following work was carried out. $Ph_2C:CH_2$ and $(p\text{-}MeC_6H_4)_2C:CH_2$ gave absolutely no color with Br. α-$C_{10}H_7MgBr$ and AcOEt give *α,α-dinaphthylmethylcarbinol*, m. 146°, giving an intense malachite green color with concd. H_2SO_4 and a brick-red color with Br. With concd. HCl there results *α,α-dinaphthylethylene*, m. 107°; concd H_2SO_4 gives the same color as with the carbinol; the ethylene does not show a characteristic behavior with Br; in CCl_4 Br gives a *mono-Br deriv.*, m. 148°; excess of Br gives a *tetra-Br deriv.*, m. 69-70°, sol. in 30% oleum with a grass-green color. Attempts to prep. $(C_{10}H_7)_2C:CHPh$ by the action of $PhCH_2CO_2Et$ upon α-$C_{10}H_7MgBr$ gave only $PhCH_2COCHPhCO_2Et$. *Biphenylphenylethylene*, $PhC_6H_4CPh:CH_2$, m. 94.5°; concd H_2SO_4 gives a brick-red color; Br vapor colors the compd. greenish gray; *Br deriv.*, m. 162°; warming with concd. H_2SO_4 gives an intense red-violet color, Br vapor colors the compd. black-violet and the color is very stable; the *di Br deriv.* m. 155°, Br vapor does not color the crystals. $(PhC_6H_4)_2C:CH_2$, m. 211°, gives a *Br deriv.*, m. 187-8°, colored by Br vapor a red brown, which color quickly disappears. *di Br deriv.*, m. 194.5° *asym-Diphenylmethylethylene*, $(PhC_6H_4)_2C.CHPh$, light yellow, m. 165-6°, sol. in concd H_2SO_4 with a deep red-violet color; Br vapor gives a deep green color stable for only 1-2 secs.; *Br deriv.*, m. 150-2°, Br vapor gives a dirty grayish black color, stable for about 1 hr. *asym-Diphenylphenylethylene*, m. 192-3°, difficultly sol. in cold concd. H_2SO_4, and giving a deep bluish red color on warming. Br vapor gives a grass-green color, stable for only 1 sec.; *Br deriv.*, m. 201-2°; Br vapor gives no characteristic color. C. J. WEST

Organic arsenic compounds. I. J. KLIPPEL. *Recueil Chim.* **10**, 777-83 (783 English)(1930).—*Methylphenyl α-naphthylarsine*, $C_{17}H_{15}As$, m. 60.0-0.5° was obtained by the action of PhMgBr on $Ph(C_{10}H_7)AsCl$. On addn. of Cl or CNBr to this compd., and after decompn. of the addn. products by heating *phenyl-α-naphthylchloroarsine*, $C_{16}H_{12}AsCl$, m. 46.0-6.5°, and *phenyl-α-naphthylcyanoarsine*, $C_{16}H_{12}AsCN$, m. 95.5-100°, resp., were formed. The chloride and cyanide were converted by hydrolysis into *phenyl α-naphthylarsine oxide*, m. 116.5-7.5° which on oxidation by H_2O_2 gave the *arsonic acid*, m. 189.0-9.5°. The chloride and oxide described by Blicke and Smith (*C. A.* **24**, 830) as thick non-crystg. oils are cryst. when in a pure condition. J. KUČERA

The action of bromine on naphthylamine- and aminonaphtholsulfonic acids. GUSTAV HELLER, HERBERT ARNOLD AND JOHANNES SCHMIDT. *Z. angew. Chem.* **43**, 1132-7(1930); cf. *C. A.* **22**, 3653.—1,4-, 1,5- (I) and 1,8-$NH_2C_{10}H_6SO_3H$ react with an excess of Br_2, yielding the corresponding *2,4-di-Br derivs.*, while the 2,5-, 2,6- and 2,7-compds. give the *1-Br derivs.* The products from the 2,8- and 2,1-compds. were not characterized since the reaction in these cases was not under control. 2,3,6- (II) and 2,6,8-$NH_2C_{10}H_5(SO_3H)_2$ (III) yield *dibromonaphthalenesulfonic acids* of unknown structure. In each case 1 SO_3H group has been substituted for a Br atom. In the product from II, a Br atom occupies position 1. Unknown *mono-Br derivs.* of I and III were also prepd. SO_3H derivs. of 1,2-, 1,8-, 2,5- and 2,8-$NH_2C_{10}H_6OH$ yield bromonaphthoquinones upon reaction with Br_2; the halogen replaces the SO_3H group when an excess is used. 2,5,7 (IV) and 2,8,6-$NH_2(OH)C_{10}H_5SO_3H$ and 2,8,3,6-$NH_2(OH)C_{10}H_4(SO_3H)_2$ all yield *1,3,6,7-tetrabromo-2-amino-5,8-naphthoquinone* (V), m. 241°, *Ac deriv.* m. 255°, *di Ac deriv.* m. 160-1°. V reacts with $PhNH_2$, yielding the *anilinotribromo deriv.*, $C_{16}H_9O_2N_2Br_3$, m. 215-6°. Upon reduction of V with $SnCl_2$, 1 of the Br atoms is lost; the product $C_{10}H_6O_2NBr_3$ m. > 300°. IV also reacts with 2 mols. of Br_2, the probable product being *1,3-dibromo-2,5,7 aminonaphtholsulfonic acid*. 1,8,4-$NH_2(OH)C_{10}H_5SO_3H$ and 1,8,4,6-$NH_2(OH)C_{10}H_4(SO_3H)_2$ (VI) both give *2,4,7-tribromo-1-amino-5,8-naphthoquinone*, while *2,4,6,7-tetrabromo-1-amino-5,8-naphthoquinone*, m. 255° (*Ac deriv.* m. 184°) is derived from both 1,8,5-$NH_2(OH)C_{10}H_5SO_3H$ and VI. VI also yields *2,4,x-tribromo-1,8,6-aminonaphtholsulfonic acid* and the K salt of *1,2,4-tribromo-5,8-naphthoquinone-6-sulfonic acid*. This last product indicates that the NH_2 group has been replaced by Br. It was isolated with 2.5 mols. of H_2O, 1.5 mols. of which was



driven off by heating at 150°. The bromination of 1,8,3,6-$NH_2(OH)C_{10}H_4(SO_3Na)_2$ in KCl soln. gives the K salt of *2, 4(?)-dibromo-1-amino-5,8-naphthoquinhydrone-3,6-disulfonic acid*, the reduction of which compd. leads to the formation of the *hydroquinone compd.*, $C_{10}H_7O_8NS_2Br_2$. By heating 0.5 g. of 1,2,4-$NH_2(OH)C_{10}H_5SO_3H$ (VII) with 1 cc. of 50% Br_2 in HOAc at 100°, 0.4 g. of 3,4,1,2-$Br_2C_{10}H_4(:O)_2$ was isolated. When a free flame was used in heating VII with Br_2, 3,2,1,4-$Br(HO)C_{10}H_4(:O)_2$ was obtained. 1,2,4,6-$NH_2(OH)C_{10}H_4(SO_3H)_2$ yields the K salt of *4-bromo-1,2-naphthoquinone-6-sulfonic acid*.

I. M. LEVINE

Reactivity of substituents in the C_5-nucleus. VINCENT JACOBI. *J. prakt. Chem.* **129**, 55–96(1931).—Because cyclopentadiene is not only difficult to prep. but polymerizes quickly at room temp., indene (I) has been used in this study. Much of the chemistry of I is reviewed. Details are given of the reduction of I and the prepn. of its di-Br deriv. Distn. of dibromohydrindene at ordinary temp. gives 5-bromoindene, b_{16} 120°, m. 36°; a trace of concd. H_2SO_4 gives an intense bluish red color; oxidation gives 4-$BrC_6H_3(CO_2H)_2$. Diketohydrindene (II) and *p*-$C_6H_4(CHO)_2$, heated at 110–20°, give *p-aldehydobenzalindandione*, $C_6H_4(CO)_2C{:}CHC_6H_4CHO$, pale yellow, m. 173°; concd. H_2SO_4 gives an intense orange color; $PhNHNH_2$ gives *p*-$C_6H_4(CH{:}NNHPh)_2$ With twice the amt. of II, there results *terephthalidenebisdiketohydrindene*, m 293°; a by-product, yellow, m. over 300°. II and 1 mol MeMgI give unchanged II indicating the structure C_6H_4 C(OH)·CH.CO, even 2 mols MeMgI give unchanged II; 5 mols. MeMgI give *1,3-dihydroxy-2-methylindene*, b_{10} 126°; repeated vacuum distn. or distn. at atm. pressure splits off 1 mol. H_2O, giving *α-methylindone*. The 5-Br deriv. of I and Mg in Et_2O give the Grignard reagent after heating several days; with H_2O it gives I. *1,2,5-Tribromohydrindene (5-bromoindene dibromide)*, oil which decomps. very easily; cooking with 10% EtOH gives *5-bromoindene hydroxybromide*, m. 80.5–1.5°. I dibromide, b_{10} 143.5–4.5°, m. 31.5–2.5°, gives with 10% EtOH *2-ethoxybromohydrindene*, oil, the *2-MeO deriv.* is also an oil. Distn. of the EtO deriv. *in vacuo* gives *1-bromoindene*, b_{11} 135.5–6°; concd. H_2SO_4 gives an intense ruby-red color; the Mg deriv. with CO_2 gives *indene-1-carboxylic acid*, m. about 70° (decompn.). Distn. of indene dibromide at atm. pressure gives *3-bromoindene*, b_{11} 110–20°; Mg in Et_2O followed by CO_2, gives the *3-carboxylic acid*, m. 160° (decompn.). A by-product is *3-indenophenone (diindyl ketone)*, m. 235°; indene is also formed in small amts. *1,2,3-Tribromohydrindene (3-bromoindene dibromide)*, oil which readily decomps.; 10% EtOH gives *3-bromoindene hydroxybromide*, m. 90°. I and Br in H_2O, boiled 3 hrs., give a *tribromoindene*, pale yellow, m. 133.5–4°; HNO_3 gives a dibromophthalic acid, showing that 2 of the Br atoms must be in the benzene ring

C. J. WEST

Alkali organic compounds. OTTILIE BLUM-BERGMANN. *Ann* **484**, 26–51(1930).—Schlenk and Bergmann (*C. A.* **22**, 4495), by the action of Na upon 1-benzohydrylidene-3-phenylindene (I), obtained 2 dihydro derivs., m. 174.5–5° (II) and 133–4.5° (III); Wieland and Kloss (*C. A.* **23**, 3696), by the reduction of 1-benzohydrylidene-3-phenyl-2-chloroindene (IV), obtained a 3rd isomer (V), m. 115°. In order to clear up this matter, II and V have been synthesized. IV is dimorphous, crystg. from benzine as orange-red cubes, m. 147–8°, and red-violet needles, m. 157–8°; reduction with HI and red P in AcOH gives V, needles, m. 115°, or rhombic leaflets, m. 130–1.5°; the leaflets are changed into the needles on repeated crystn. The Li deriv. (VI) of 3-phenylindene and $BzPh$ give I. VI and $ClCO_2Me$ give *di-Me 3-phenylindene-1,1-dicarboxylate*, m. 105–7°; catalytic reduction gives the *dihydro deriv.*, m. 102–3.5°; the free *dicarboxylic acid* m. 175–7° (decompn.); heated above its m. p., it gives *3-phenylhydrindene-1-carboxylic acid*, b_{14} 227–9°, m. 143–4.5°; *Me ester*, b_{13} 204.5–5°; the latter with PhMgBr gives *3-phenyl-1-(α-hydroxybenzohydryl)hydrindene*, m. 122–4°, which loses H_2O when heated with AcCl, giving V. The Li deriv. of fluorene and MeI give 9,9-dimethylfluorene and the 9-Me deriv. The Li deriv. of indene and Ph_2CHBr give 1-benzohydrylindene, m 163–4°. VI and Ph_2CHBr give II, m. 174.5–5°; the by-products

(V) (II) (III)

include $(Ph_2CH)_2$ and 3,3′-diphenyl-1,1′-diindenyl; a *dimer* of 3-phenylindene, yellow, m. 207–9°, and a *compd.* $C_{18}H_{22}$, leaflets, m. 166–7°, and yellow prisms, m 162–4.5°; reduction of the last gives the *compd.* $C_{18}H_{24}$, m. 182–4°. The Li deriv. of 2-phenylindene and Ph_2CHBr give *1-benzohydryl-2-phenylindene*, m. 175°, whose *dihydro deriv.* m. 151°. This shows that the compd. $C_{28}H_{22}$ above is not produced by the wandering

of the Ph group. The action of Al-Hg upon I gives a mixt. of II and III. Reduction of III with Na and AmOH gives 1-benzohydryl-3-phenylhydrindene, m. 133–5°, also obtained by reducing V. In the reduction of anthroic acid, there results a *double compd.* of this acid with the tetrahydro acid, $C_{15}H_{12}O_2$, m. 190–2°, green luster. The action of CO_2 upon the Li deriv. of anthracene gives *9,10-dihydro-9,10,10-tricarboxylic acid*, crystg. with 1 mol. Et_2O, m. 289–92° (decompn.); heating 13 hrs. at 100° splits off the Et_2O; further heating for 14 days also splits off 1 mol. CO_2; *tri-Me ester*, m. 147.5–8°. Heating the acid in AcOH gives α-9,10-dihydroanthracene-9,10-dicarboxylic acid, m. 162–3.5°. Ph_2CNa and $CO(OPh)_2$ give Ph_2CCO_2Ph, m. 124–7°; $CO(OEt)_2$ gives Ph_2CCO_2Et, m. 118–20°; $(Ph_2CNa)_2$ and $CO(OPh)_2$ give $(PhC:)_2$. The Li deriv. of fluorene and $CO(OMe)_2$ give Me biphenyleneacetate and *dibiphenyleneacetone*, m. 230–2° (decompn.). Ph_2CHNa and $CO(OMe)_2$ give $(Ph_2CH)_2CO$, m. 134–4.5°. $(Ph_2CNaCH_2)_2$ and $CO(OMe)_2$ give 1,1,4,4-tetraphenylcyclopentan-5-one. The di-Li deriv. of anthracene and $CO(OMe)_2$ give *bisdihydroanthracyl ketone*, m. 238–40° (evolution of CO); in its thermal decompn., 88.5% of the theory of CO_2 is evolved and a mixt. of anthracene and its dihydro deriv. is formed. The Na deriv. of anthracene behaves in the same way. $(Ph_2CH)_2CO$ with Na in Et_2O gives the *Na salt* of the enolate, $C_{27}H_{21}ONa$; dry distn. gives tetraphenylallene and 1,1,3,3-tetraphenylpropylene. C. J. West

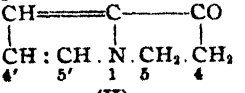
Coupling of diazonium compounds with 2-methoxy-3-naphthoic acid. G. B. Jambuserwala and F. A. Mason. *J. Soc. Dyers Colourists* **46**, 339–41(1930).—The Me ether of β-hydroxynaphthoic acid will couple in H_2O with diazotized *p*-, *o*-, and *m*-nitroaniline, 4- and 5-nitro-*o*-anisidine, sulfanilic acid, benzidine and tolidine. Milton Harris

Keto-oxidation product of α-acetylacenaphthene. K. Dziewoński and J. Reiss. *Bull. intern. acad. polonaise* **1930A**, 62–5.—Contrary to Graebe and Haas (*Ann.* **327**, 77–103(1903)) oxidation of 5-acetylacenaphthene (best prepd. by the action of $AlCl_3$ on AcCl and acenaphthene without solvent) with $Na_2Cr_2O_7$ and AcOH at 50° gives only traces of 4,1,8-$C_{10}H_5Ac(CO_2H)_2$, the main products being *5-acetylacenaphthenequinone*, m. 192–3° [*bisphenylhydrazone*, m. 240–2°; *dioxime*, m. 275–8° (decompn.)], and *2,2'-diketo-5,5'-diacetyldiacenaphthylidene*, m. 295° (decompn.). B. C. A.

Derivatives of 3-bromoacenaphthene. K. Dziewoński, Mlle. J. Schoen and Mlle. A. Glazner. *Bull. intern. acad. polonaise* **1929A**, 636–49.—Oxidation of 3-bromoacenaphthene by $Na_2Cr_2O_7$ in AcOH at 30° yields, besides 4-bromonaphthalic acid, 3-bromoacenaphthenequinone, m. 235–6° (Graebe, *Ann.* **327**, 77–103(1903), gives m. p. 194°) [monophenylhydrazone, m. 179–80°; bisphenylhydrazone, m. 225–6° (literature 153° and 134°, resp.); *dioxime*, m. 230–1° (decompn.); *3-bromoacenaphthaphenazine*, from the foregoing quinone and *o*-$C_6H_4(NH_2)_2$, m. 261–3°], and *3,3'-dibromobiacenedione*, $\left(C_{10}H_{5}Br\begin{matrix}C:\\CO\end{matrix}\right)_2$, m. 320–1° (for nomenclature, cf. *C. A.* **20**, 1234). Nitration of 3-bromoacenaphthene in AcOH gives mainly *3-bromo-4-nitroacenaphthene*, m. 159–61°, converted by $Na_2S_2O_4$ into *3-bromo-4-aminoacenaphthene*, m. 133°. The orientation of these derivs. is established by the further reduction of the latter, by means of Na-Hg and alc., to the known 3-aminoacenaphthene. 3-Bromo-4-nitroacenaphthene is oxidized by $Na_2Cr_2O_7$ to *4-bromo-5-nitronaphthalic acid*, m. 295° (*anhydride*, m. 312°; *Me ester*, m. 162°). Two isomeric SO_3H acids, termed "α" and "β," resp., are obtained by the interaction of $ClSO_3H$ and 3-bromoacenaphthene at the ordinary temp., and are sepd. by means of their Na salts. *3-Bromoacenaphthene-α-sulfonic acid* forms the more sparingly sol. *Na salt* (*aniline salt*, m. 260–1°; *β-naphthylamine salt*, m. 265–6°; *chloride*, m. 134–5°; *amide*, m. 137–8°); oxidation affords *3-bromo-α-sulfonaphthalic anhydride*, isolated as its *Na salt*, *3-Bromoacenaphthene-β-sulfonic acid* (*aniline salt*, m. 256–7°. *chloride*, m. 192–3°; *amide*, m. 233–4°, *Et ester*, m. 140–1°) yields a similar naphthalic acid on oxidation. Sulfonation with H_2SO_4 (d. 1.84) at 80–90° converts 3-bromoacenaphthene into a *disulfonic acid*, isolated as the *Ba salt*; the *di-Na salt* ($+3H_2O$) is readily sol. in water [*dichloride*, m. 181–2°; *diamide*, m. 289° (decompn.); *Et ester*, m. 164°]. B. C. A.

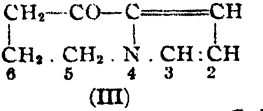
Reduction products of the hydroxyanthraquinones. XII. Gordon F. Attree and Arthur G. Perkin. *J. Chem. Soc.* **1931**, 144–73; cf. *C. A.* **24**, 2456.—2-Methoxyanthraquinone (I) in H_2SO_4 and Cu powder, gradually added and heated to 140° for 1 hr., and the resulting product treated with Ac_2O and C_5H_5N, give the *acetate*, m. 152–4°, of *3-methoxy-9-anthranol* (II), m. 108–9°. II with $FeCl_3$-AcOH and EtOH gives about 30% of *3,3'-dimethoxydianthrone*, m. 215–7° to a green liquid; concd. H_2SO_4 gives a pale yellow soln.; the main product of the reaction is I. *3,3'-Dimethoxydianthranyl 9,9'-diacetate*, m. 228–30°, sol. in H_2SO_4 with a violet-red tint; I in C_5H_5N

transforms this to 3,3'-dimethoxydianthraquinone, yellow, m. 294–5°; the latter in C_5H_5N, exposed to light for 2 weeks, gives 2,2'-dimethoxynaphthadianthrone, orange-red, does not m. 340° and gives a red soln. in H_2SO_4. Isoanthraflavic acid (III), reduced by $SnCl_2$-HCl, gives 3,6-dihydroxy-9-(isoanthraflavic acid)anthrol, m. 183–4° (Roemer and Schwarzer, *Ber.* **15**, 1041(1882), give 173°); $FeCl_3$ in AcOH and EtOH gives *3,3',6,6'-tetraacetoxy-9,9'-dianthranyl diacetate*, pale yellow, m. 280–2°; hydrolysis with HCl-AcOH gives *3,3',6,6'-tetrahydroxydianthrone*, pale yellow, darkens 270°, turns green 300° and does not have a definite m. p. The hexaacetate does not give a dianthraquinone with I in C_5H_5N. III gives a *di-Me ether* (IV), yellow, m. 215–7°; with Cu and H_2SO_4 this yields the *acetate*, pale yellow, m. 180–1°, of *3,6-dimethoxy-9-anthranol*, m. 158–60°; the latter with $FeCl_3$ in AcOH gives *3,3',6,6'-tetramethoxy-9,9'-dianthrone*, m. 242–3°, whose *diacetate*, yellow, m. 255–6°, does not react with I in C_5H_5N. IV and $SnCl_2$-HCl in AcOH give *3-methoxy-6-acetoxy-9-anthranyl acetate*, m. 197–9°, sol. in H_2SO_4 with a bluish red color, becoming yellow; hydrolysis with HCl-AcOH gives *6-hydroxy-3-methoxyanthranol*, m. 234–6°, giving a yellow soln. with a green fluorescence in H_2SO_4; oxidation of the acetate with CrO_3 in AcOH gives the *mono-Me ether* of III, yellow, m. 283–5°, as the *Ac deriv.*, m. 194–6°, giving a crimson color in H_2SO_4; the mono-Me ether also results in very small yields in the action of Me_2SO_4 on III. *6,6'-Dihydroxy-3,3'-dimethoxydianthrone* m. 292–5°. *3,7-Dihydroxy-9-anthranol* and $FeCl_3$-AcOH give *3,3',7,7'-tetrahydroxydianthrone*, m. 315–8°, sol. in H_2SO_4 with an orange-yellow color; the *tetraacetoxy diacetate* darkens about 290° but does not have a definite m. p.; H_2SO_4 gives a scarlet color, changing through brown to green. 2,2',3,3'-Tetrahydroxydianthrone, from hystazarin (V) through acetylhystazarinanthrol, with Ac_2O gives the *tetra-Ac deriv.*, pale yellow, m. 274–7°; with C_5H_5N there results the *tetra-Ac diacetate*, m. 293–5°, sol. in H_2SO_4 with a red color, changing to green and then brown. The di-Me ether of V, with $SnCl_2$-HCl-AcOH, gives the *acetate*, m. 169–71°, of *2,3-dimethoxyanthranol*, pale yellow, m. 143–6°; with $FeCl_3$-AcOH there results *2,2',3,3'-tetramethoxydianthrone*, m. 243–5°, sol. in H_2SO_4 with an orange-red color; the *diacetate* m. 194–6°. Oxidation of the anthrone with $(NH_4)_2S_2O_8$ gives *2,2',3,3'-tetramethoxydianthraquinone* (VI), pale yellow, m. 290–1°, sol. in H_2SO_4 with a dull violet color, quickly passing to a blackish brown; C_6H_6 gives a deep green soln. Exposure to light in C_5H_5N-EtOH for 20 days gives *2,2',3,3'-tetramethoxyhelianthrone*, m. 287–8°, sol. in H_2SO_4 with a deep indigo-blue color; HCl-AcOH at 190° for 3 hrs. splits off the MeO groups, giving the *tetra-HO deriv.*, iridescent metallic leaflets; *tetra-Ac deriv.*, orange, m. 295–7°; CrO_3 and AcOH oxidize this to *2,2',3,3'-tetraacetoxy-1,1'-dianthraquinonyl*, pale yellow, m. 200°, and then 268–70°; H_2SO_4 gives a red-brown soln. Hydrolysis gives the *tetra-HO deriv.*, dull yellow, does not m. 360° and gives a green-blue soln. in alkalies and a brick-red color in H_2SO_4; it dyes Sn-, Al-, Fe- and Cr-mordanted calico, producing bright orange, dull red purple, purple and dull brown shades. VI in C_5H_5N and EtOH, exposed to the light for 6 weeks, gives *2,2',3,3'-tetramethoxynaphthadianthrone*, orange needles; the *tetra-HO deriv.* forms scarlet needles, sol. in H_2SO_4 with a violet-red color; it possesses little affinity for mordanted calico and is a poor dye toward wool mordanted with Sn, Al, Fe or Cr; *tetra-Ac deriv.*, yellow, does not m. 360°. *4,4'-Dihydroxydianthrone*, m. 256–8°, sol. in H_2SO_4 with an orange-red color; the *diacetoxy diacetate* m. 265–7°. *1-Methoxyanthrone* m. 129–31°; $FeCl_3$-AcOH gives *1,1'-dimethoxydianthrone*, pale yellow, does not m. 330°; the *diacetate*, pale yellow, m. 290–1°; the crimson soln. in H_2SO_4 changes to violet and then blue on standing. Iodine and C_5H_5N give *1,1'-dimethoxydianthraquinone*, pale yellow, m. 315–6°; oxidation of a colloidal soln. with alk. $K_3Fe(CN)_6$ did not have any effect; however, exposure of a Me_2CO soln. to the light for 1 month gives *4,4'-dimethoxynaphthadianthrone*, orange-red, does not m. 360° and gives with H_2SO_4 a highly fluorescent, crimson soln.; HBr and AcOH give the corresponding *4,4'-di-HO deriv.*, scarlet needles, does not m. 360°. The other product of the action of light is *4,4'-dimethoxyhelianthrone*, salmon, does not m. 360°, gives a violet color in H_2SO_4; the 4,4'-di-HO deriv., orange-red needles, was insol. in alkalies and does not appear to give an Ac deriv. Anthrarufin di-Me ether (VII) and $SnCl_2$-HCl in AcOH give *1,5-dimethoxyanthrone*, brown-red, m. 181–2°, giving a red soln. in H_2SO_4, quickly changing to green-blue; *acetate*, pale yellow, m. 169–71°. The anthrone and $FeCl_3$ in AcOH give *1,1',5,5'-tetramethoxydianthrone*, m. 305–7°, which is not attacked by Ac_2O and C_5H_5N or by I or $(NH_4)_2S_2O_8$. VII and $SnCl_2$-HCl at 65° for 3 hrs. give *10-hydroxy-1,5-dimethoxyanthrone*, violet, m. 153–5°, sol. in H_2SO_4 with a pure blue color; boiling the mixt. for 1 hr. gives *1-hydroxy-5-methoxyanthrone*, pale yellow, m. 131–3°; *1-acetoxy acetate*, yellow, m. 161–3°; the EtOH soln. has a strong blue fluorescence. *1,1'-Dihydroxy-5,5'-dimethoxydianthrone*, pale yellow, m. 287–9°, sol. in H_2SO_4 with an



orange-yellow color, quickly passing to greenish blue; *1,1'-diacetoxy diacetate*, pale yellow, m. 250–2°. Chrysazin di-Me ether (VIII) yields *1,8-dimethoxyanthrone*, yellow, m. 196–7°; air oxidation of an alk. soln. gives *1,1',8,8'-tetramethoxydianthrone*, does not m. 340°, gives a red-brown color in H_2SO_4, rapidly changing to dull green, is unchanged by prolonged digestion with Ac_2O and C_5H_5N. $SnCl_2$-HCl and VIII give *1-hydroxy-8-methoxyanthrone*, pale yellow, m. 183–5°; the *1-acetoxy acetate*, m. 164–5°. *1,1'-Dihydroxy-8,8'-dimethoxydianthrone*, pale yellow, does not m. below 330°; Ac compd., m. 284–7°. Alizarin 2-Me ether and $SnCl_2$-HCl give 1-hydroxy-2-methoxyanthrone (IX), oxidized to *1,1'-dihydroxy-2,2'-dimethoxydianthrone*, yellow, m. 195–7°, the *1,1'-diacetoxy diacetate* m. 242–5°; IX and I in C_5H_5N give *4,4'-dihydroxy-3,3'-dimethoxyhelianthrone*, iridescent magenta-like leaflets, does not m. 330°, sol. in H_2SO_4 with an intense greenish blue color; various other methods of prepn. are given. HCl and AcOH give the *tetra-HO deriv.*, maroon-colored, does not m. below 360°; H_2SO_4 gives a deep blue color; NH_4OH gives a violet color; it does not dye mordanted calico but has weak tinctorial power toward mordanted wool; Ac_2O and C_5H_5N give *4,4'-dihydroxy-3,3'-diacetoxyhelianthrone*, iridescent, chocolate-colored needles, m. about 325°. *1,1',2,2'-Tetrahydroxydianthrone*, pale yellow, m. 240–1°; *tetra-Ac deriv.*, m. 245–7°. Purpuroxanthin di-Me ether, on reduction, gives *10-hydroxy-1,3-dimethoxyanthranol*, red, m. 156–8°; reduction of the di-Me ether with $SnCl_2$-HCl in hot AcOH gives a *tri-Ac deriv.*, yellow, m. 154–5°, of 1,3-dihydroxy(purpuroxanthin)anthrone, m. 217–9°. *3,4-Dimethoxy-9-anthranyl acetate*, yellow, m. 146–8°; the *Me ether*, yellow, m. 116–8°. C. J. West

The action of organomagnesium compounds upon furalacetophenone. New ketones in the furan ring. N. N. Maxim. *Bul. soc. chim. România* **12**, 24–7 (1930); cf. *C. A.* **25**, 513.—M. allowed organomagnesium compds. to react upon furalacetophenone and always obtained satd. ketones in the furan ring according to the following equation $2\text{-}C_4H_3OCH{:}CHCOPh + RMgX \longrightarrow 2\text{-}C_4H_3OCHRCH_2COPh$. The furalacetophenone was prepd. according to Kostanecki and Podrajanski (*Ber.* **29**, 2248) by allowing furfural to act upon PhCOMe in the presence of dil. NaOH. From this, M. prepd. *β-furylbutyrophenone*, $MeCH(C_4H_3O)CH_2COPh$, *β-furylvalerophenone*, $EtCH(C_4H_3O)CH_2COPh$ and *β-phenyl-α-furylpropiophenone*. These ketones have been characterized by their semicarbazones and oximes. The yield is almost quant. This reaction can be used as a general method of prepg. satd. ketones in the furan ring. The mechanism of the reaction will be published elsewhere. F. R. G.



Preliminary work to ring syntheses of porphyrins, etc. IV. A bromovinylpyrrole and its reactions. Hans Fischer and Oskar Süs. *Ann.* **484**, 113–30 (1930); cf. *C. A.* **25**, 961.—2,4-Dimethyl-5-carbethoxypyrrole-3-acrylic acid (I) and Br in CS_2 give a *dibromide*, $C_{12}H_{14}NO_4Br_2$, which does not have a sharp m. p.; the Br is labile and with Me_2CO on the H_2O bath 60% I is regenerated; with EtOH-H_2O on the boiling H_2O bath there results *2,4-dimethyl-5-carbethoxy-3-ω-bromovinylpyrrole* (II), m. 158° (decompn.). Heated with HI-AcOH at 100° for 2 hrs., II is transformed to dimethylpyrrole, catalytic reduction of II gives cryptocarbethoxypyrrole; Br gives a *dibromide*; AgCN in MeOH gives *2,4-dimethyl-5-carbethoxy-α,β-3-dimethoxyethylpyrrole*, m. 112°; Ag or Ag or Cu gives the same product; with EtOH in place of MeOH there results *2,4-dimethyl-5-carbethoxypyrrole-3-ω-vinyl ether*, m. 87°. One mol. II and 1 mol. SO_2Cl_2 give a *mono-Cl deriv.*, $C_{11}H_{13}O_2NClBr$, m. 168°; 2 mols. SO_2Cl_2 give *2-formyl-4-methyl-5-carbethoxy-3-bromovinylpyrrole* (III), m. 140°; the *aldazine* m. 230° (decompn.); the *phenylhydrazone* m. 142° (decompn.); condensation of III and cryptopyrrole with HBr give the *methene-HBr*, $C_{19}H_{21}O_2N_2Br_2$, brick-red, blackens 170° but does not m. 300°. Hydrolysis of III gives *2-formyl-3-bromovinyl 4-methyl-5-pyrrolecarboxylic acid* m. 238° (decompn.), which condenses with cryptopyrrole to a *methene-HBr*, $C_{17}H_{20}ON_2Br_2$, reddish brown needles. Three mols. SO_2Cl_2 and II give a di-CO_2H acid, whose *α-Me α'-Et ester*, $C_{12}H_{14}O_4NBr$, m. 131°; *di-Et ester*, m. 115°; the free *acid*, $C_8H_8O_4NBr$, slowly carbonizes above 230°; catalytic reduction gives 3-ethyl-4-methylpyrrole-2,5-dicarboxylic acid. The *Et ester* (IV) of I, m. 134°, results from I, EtOH and HCl, or by condensation of 2,4-dimethyl-5-carbethoxypyrrole and $HO_2CCH_2CO_2Et$ with $PhNH_2$; the *dibromide* m. 121° (decompn.); the Br is removed by Zn in AcOH, giving IV, while catalytic reduction gives *Et 2,4-dimethyl-5-carbethoxypyrrole-3-propionate*, m. 73°; EtOH-KOH gives *2,4-dimethyl-5-carbethoxy-3-ω-carbethoxy-ω-ethoxyvinylpyrrole*, m. 136°, and a Br-contg. acid, m. 196° (decompn.); with MeOH a compd., $C_{16}H_{23}O_6N$, m. 178°, results. Oxidation of I with CrO_3 gives 2,4-dimethyl-5-carbethoxypyrrole-3-carboxylic acid, m. 271°. C. J. West

New derivatives of pyrrole. I. Synthesis of 3-keto-4,5-dihydro-di-(1,2)-pyrrole and of 8-keto-5,6,7,8-tetrahydropyrrocoline. George R. Clemo and George R.

RAMAGE. *J. Chem. Soc.* **1931**, 49–55.—K pyrrole and $ClCH_2CO_2Et$ in C_6H_6, heated 0.5 hr. at 100°, give the *Et ester*, b_{20} 112°, of *1-pyrrylacetic acid*, m. 91°; *amide*, m. 169°. *β-1-Pyrrylpropionic acid*, m. 62°; *Et ester*, b_{23} 122°; *amide*, m. 81°. Attempts to effect ring closure were unsuccessful. It was also not possible to effect ring closure with *succinobutylimide*, b_{17} 140°. K pyrrole and *p*-$MeC_6H_4SO_2CH_2CH_2Cl$ give *1-β-chloroethylpyrrole*, b_{20} 84°; *β-cyano deriv.* (I), b_{20} 140°; *1-γ-chloropropylpyrrole*, b_{15} 87°. The last compd. is recovered unchanged after prolonged boiling with EtOH-KOH; $AlCl_3$ also failed to effect ring closure. Passing dry HCl through I in dry Et_2O contg. $ZnCl_2$ gives *3-keto-4,5-dihydro-di-(1,2)-pyrrole* (II), m. 54°, best isolated through the *semicarbazone*, m. 211°; *piperonylidene compd.*, pale yellow, m. 194°. $EtO_2CCH_2CH_2COCl$ and K pyrrole give *Et β-1-pyrroylpropionate*, m. 50°; treatment with Na in $C_6H_4Me_2$ and distn. with $CaCl_2$ failed to remove EtOH. Levulyl chloride and K pyrrole give *β-1-pyrroylethyl Me ketone*, b_{16} 148° (*phenylhydrazone*, m. 131°; *semicarbazone*, m. 190°); treatment with acids and alkalies always resulted in amide hydrolysis. *γ-1-Pyrrylbutyronitrile*, b_{23} 152°, with $ZnCl_2$ and HCl, gives *8-keto-5,6,7,8-tetrahydropyrrocoline* (III), m. 34°; *semicarbazone*, m. 193°; *piperonylidene deriv.*, yellow, m. 136°.

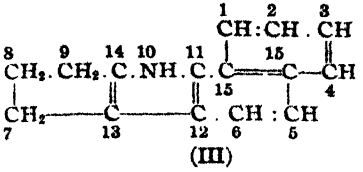
Cyclotellurobutane (tetrahydrotellurophen). GILBERT T. MORGAN AND FRANCIS H. BURSTALL. *J. Chem. Soc.* **1931**, 180–4.—$(CH_2)_4I_2$ and amorphous Te, heated at 130–40° for 5 hrs., give *cyclotelluributane 1,1-diiodide* (I), purple plates or bright red prisms, m. 149–50°; reduction with SO_2 in boiling H_2O gives *cyclotellurobutane* (II), b_{122} 105–6°, b_{761} 166–7°, n_D^{18} 1.6175, penetrating and unpleasant odor, oxidizes readily in the air, reacts explosively with concd. HNO_3 and gives a red color with H_2SO_4; the *mercurichloride* m. 146–7°. II and Cl give *cyclotelluributane 1,1-dichloride*, m. 111–2°; *dibromide* (III), m. 130°, decomps. at 210°. III and IV in equimol. proportions in H_2O or II and Na_2CO_3 or NaOH sufficient to remove half the Br, give the *1,1'-oxydibromide*, $[(CH_2)_4TeBr]_2O$, m. 207° (decompn.); alkalies convert this into the *1-oxide* IV, $(CH_2)_4TeO$, m. 241° (decompn.), also obtained by the oxidation of II or the action of excess alkali on the dihalides; halogen acids regenerate the corresponding dihalides II and MeI give *cyclotelluributane 1-methiodide*, vaporizes without melting at 240°. $(CH_2)_4Br_2$ and Al telluride, heated at 125° for 2 hrs., give *1-δ-bromobutylcyclotelluributane 1-bromide*, $(CH_2)_4Te[(CH_2)_4Br]Br$, obtained from the Me_2CO and EtOH exts. of the reaction product, m. 152 3°; above its m. p. it dissocs. into $(CH_2)_4Br_2$ and II; the corresponding *iodide* m. 175–6° (decompn.); the aq. ext. of the above reaction product contains *tetramethylene-α,δ-biscyclotelluributane 1,1'-dibromide*, $(CH_2)_4TeBr(CH_2)_4TeBr(CH_2)_4$, crystg. with 1 mol. H_2O, m. 225° with dissocn. to $(CH_2)_4Br_2$ and II; *diiodide*, deep yellow, decomps. 215°.

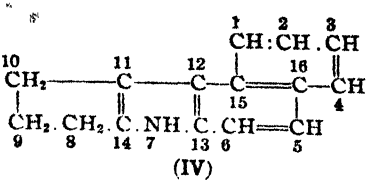
C. J. WEST

Heterocyclic systems containing selenium. IV. Cycloselenohexane. GILBERT T. MORGAN AND FRANCIS H. BURSTALL. *J. Chem. Soc.* **1931**, 173–80; cf. *C. A.* **24**, 4297.—$(CH_2)_6Br_2$ and Na_2Se, refluxed 2 hrs., give a mixt. of yellow polymers and a very small quantity of *cycloselenohexane* (I), b_{48} 105–6°, b_{756} 188–90°, n_D^{18} 1.5470, $d_4^{24.5}$ 1.353, $d_4^t = 1.378 - 0.00101t$; the concd. H_2SO_4 soln. develops yellow to red tints on warming; I is not oxidized in the air; *mercurichloride*, m. 193–4° (decompn.). I and I in EtOH give *cycloselenihexane 1,1-diiodide*, reddish purple, m. 82°; *1,1-dibromide*, yellow, m. 118–9°; it slowly decomps. giving $(CH_2)_6Br_2$ and Se; *1,1-dichloride*, m. 78°; *1-methiodide*, m. 149–50° (decompn.). The more sol. fraction of the polymerides (in petr. ether, b. 60–80°) is a *dimer*, $(C_6H_{12}Se)_2$, m. 92°, depolymerizes above 220°; *dibromide*, pale yellow, m. 145° (decompn.). The less sol. *polymer*, $(C_6H_{12}Se)_x$, is a waxy microscryst. powder, m. 36–7°; mol.-wt. detns. indicate approx. 12 mols. I; the *bromide* decomps. slowly and m. 94–5° (decompn.). Heating this polymer at 220° gives *2-methylcycloselenopentane* (II), b_{48} 90°, b_{764} 169–71°, n_D^{18} 1.5205, d_4^{22} 1.287, $d_4^t = 1.3115 - 0.00111t$; the dichloride is a colorless liquid, the dibromide a reddish yellow gum and the diiodide a deep red gum; *mercurichloride*, m. 112°; *1-methiodide*, m. 164° (decompn.). The constitution of II is shown by heating the dibromide, which gives $Br(CH_2)_3CHMeBr$, which was converted into the dinitrile and α-methylpimelic acid. $(CH_2)_6Br_2$ and KSeCN, refluxed in Me_2CO for several hrs., give *hexamethylene α,ζ-diselenocyanate*, thick yellow oil which decomps. on distn.; oxidation by the air gives *cyclodiseleno-*



hexane, brown, highly polymerized, m. about 40° and decomps. at 250°, giving II; oxidation of either of these compds. with HNO_3 gives ***hexamethylenediselenious acid***, decompg. 147°. The mean parachor of I (302.1) and of II (304.2) indicates that they are normal liquids. C. J. WEST

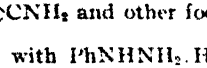
Behavior of certain thiophanes in heptane and naphtha solutions. R. W. BOST AND M. W. CONN. *Ind. Eng. Chem.* **23**, 93–5(1931).—Tetramethylene and pentamethylene sulfides have been studied along with Et_2S and thiophene, in heptane and three naphtha solns. $HgCl_2$, $KMnO_4$, H_2O_2, and MeI react with the thiophanes to form definite products easily identified and purified. Br and HgI_2 form unstable products. B. and W. state in general thiophanes resemble alkyl sulfides more than thiophene. M. C. ROGERS



Indophenin. GUSTAV HELLER. *Chem.-Ztg.* **54**, 985–7(1930); cf. *C. A.* **19**, 1277.—A theoretical discussion of the formula proposed by Steinkopf and Roch (*C. A.* **25**, 292) for the constitution of indophenin. JULIUS WHITE

Syntheses of glucosides. VII. Synthesis of 6-bromoindican. ALEXANDER ROBERTSON AND ROY B. WATERS. *J. Chem. Soc.* **1931**, 72–6; cf. *C. A.* **25**, 1232.—*Me 4-bromoanthranilate*, m. 78°, does not react with $ClCH_2CO_2Me$ when heated alone or with AcONa or C_5H_5N. 4-Bromoanthranilic acid and $ClCH_2CO_2H$, heated in 5.5% aq. KOH for several hrs. and the resulting product esterified with MeOH and H_2SO_4, give *di-Me 5-bromophenylglycine-2-carboxylate*, m. 101° (almost quant. yield); Na in C_6H_6 contg. a little MeONa gives *Me 6-bromo-3-hydroxyindole-2-carboxylate* (I), m. 192°; *di-Ac deriv.*, m. 151°. Refluxing the ester with MeOH-NaOH in N for 1.5 hrs. gives 6-bromoindoxylic acid, sepg. from H_2O as the *trihydrate*, m. 198° (decompn.); Ac_2O and AcONa give 6-bromo-1-acetyl-3-acetoxyindole, crystg. from dil. EtOH as the *hydrate*, sinters 122°, m. 150–2°. Adding aq. KOH to I and *O*-tetraacetyl-α-glucosidyl bromide in Me_2CO at 10° gives *Me 6-bromo-3-O-tetraacetyl-β-glucosidoxyindole-2-carboxylate*, m. 171°, $[\alpha]_D^{20}$ —59.7° (Me_2CO); a penta-Ac deriv. could not be obtained. Hydrolysis by heating with MeOH-KOH on the H_2O bath for 1 hr. gives the *K salt* (II) of 6-bromo-3-β-glucosidoxyindole-2-carboxylate, which forms a gel, prolonged hydrolysis by dil. HCl gives 6,6′-dibromoindigotin and glucose. II, AcONa and Ac_2O, heated on the steam bath for 1 hr. and then at 160° for 1 hr., give *penta-acetyl-6-bromoindican* (*6-bromo-1-acetyl-3-O-tetraacetyl-β-glucosidoxyindole*), m. 159°, $[\alpha]_D^{20}$ —48.8° (Me_2CO); with dry NH_3 in MeOH at 0° there results *6-bromo-3-β-glucosidoxyindole* (*6-bromoindican*), crystg. with 4 H_2O, m. 64°, $[\alpha]$ (Me_2CO), drying over P_2O_5 for 60 hrs. gives the *semi-hydrate*, m. 177°; the anhyd. compd. results by heating at 110° for 15 hrs. and at 160° for 5 min. This is rapidly hydrolyzed by warm 2% HCl and by emulsin at 35–7°, with the liberation of glucose and 6-bromo indoxyl, partly oxidized by the air to 6,6′-dibromoindigotin. Hydrolysis by warm 3% HCl in the presence of isatin gives quant. *6-bromoindirubin*, purple with green metallic luster, does not m. 340°; with p-$O_2NC_6H_4CHO$, there results *p-nitrobenzaldehyde-6-bromoindogenide*, brick-red, m. 297–8°. C. J. WEST

Action of nitric acid on polycyclic indole derivatives. IX. STEPHEN A. BRYANT AND SYDNEY G. P. PLANT. *J. Chem. Soc.* **1931**, 93–105; cf. *C. A.* **24**, 114, 1375.—In view of the widely different nature of the products obtained when HNO_3 acts on the acyl derivs. of tetrahydrocarbazole, dihydropentindole, 7,8,9,10-tetrahydro-α β-naphthacarbazole and 8,9,10,11-tetrahydro-α′,β′-naphthacarbazole, and of the deep-seated variations observed in the reactions of substances formed in such cases by the addn. of HO and NO_2 or OH and OH to the double linkage, it is of interest to extend the investigation to certain closely related types. *Cyclopentanone α-naphthylhydrazone* (I), m. 95°; the *β-deriv.* (II), m. 77°. I and dil. H_2SO_4, heated 15 min. at 100°, give *7,8-dihydro-α,β-naphthapentindole* (III), m. 167°; this is also formed by boiling I in glacial AcOH; its picrate, reddish brown, m. 167° (decompn.). III and Ac_2O contg. a little H_2SO_4, boiled 10 hrs., give the *10-Ac deriv.*, m. 157°, and the *1(?)-Ac deriv.*, yellow, m. 215°; stable toward dil. EtOH-KOH; *oxime*, m. 236° (decompn.). II and dil. H_2SO_4 give *9,10-dihydro-α′,β′-naphthapentindole* (IV), m. 103°; *picrate*, brown, m. 189° (decompn.). AcCl and IV in Me_2CO and aq. NaOH give the *7-Ac deriv.*, m. 170°; with Ac_2O and H_2SO_4 this gives the *5(?),7-di-Ac deriv.*, pale green, m. 234°, also obtained from IV and Ac_2O; partial hydrolysis gives the *5(?)-Ac deriv.*, greenish yellow, m. 239°, yielding with BzCl and KOH the *5(?)-acetyl-7-benzoyl deriv.*, pale greenish yellow, m. 163°, which may again be partially hydrolyzed to the *5(?)*-Ac deriv.; *7-Bz deriv.*, pale yellow, m. 196°; *7-carbethoxy deriv.*, m. 160°. The 7-Ac deriv., nitrated in AcOH, yields a *5(?)-NO_2 deriv.*, lemon-yellow, m. 247°; K_2CO_3 splits off the Ac group, giving the *5(?)-NO_2 deriv.* of IV, brick-red, m. 228°.



(III)

(IV)

The 7-Bz deriv. also yields a *5(?)-NO_2 deriv.*, yellow, m. 259°. The 7-carbethoxy deriv. yields a *5(?)-NO_2 deriv.*, lemon-yellow, m. 202°, and also a *di-NO_2 deriv.*, yellow, m. 220° (decompn.). 2-Methylcyclohexanone and β-$C_{10}H_7NHNH_2$, heated 0.5 hr. and the resulting oily hydrazone treated with dil. H_2SO_4, give a mixt. of *δ-methyl-8,9,10,11-tetrahydro-α',β'-naphthacarbazole* (V), m. 115° (*picrate*, dark crimson, m. 201° (decompn.)), and 12-methyl-8,9,10,11-tetrahydro-α',β'-naphthacarbazolenine, m. 92° (picrate, bright yellow, m. 166°). A mixt. of V, S and quinoline, boiled for 45 min., gives *8-methyl-α',β'-naphthacarbazole*, m. 144°; this was also synthesized from 2,3-$HOC_{10}H_6CO_2H$ and *o*-$MeC_6H_4NHNH_2$ by heating at 130° and then distg. the 8-methyl-α',β'-naphthacarbazole-6-carboxylic acid with soda lime. 5,6-Dihydro-α,β-naphthacarbazole (Ghigi, *C. A.* **24**, 3797) with Ac_2O contg. a little H_2SO_4 gives the *1(?)-Ac deriv.*, yellow, m. 253° (*oxime*, m. 292° (decompn.)). Benzopentindole gives a *7-Bz deriv.*, pale yellow, m. 187°; with HNO_3 in AcOH there results *14-nitro-6-hydroxy-7-benzoyl-6,14-dihydrobenzopentindole*, m. 169° (decompn.); 20% KOH gives *14-nitro-6-hydroxy-6,14-dihydrobenzopentindole*, m. 200° (decompn.). C. J. West

Diazotization in the pyrazole series. J. Reilly and D. MacSweeney. *Proc. Roy. Irish Acad.* **39B**, 497–504(1930).—The diazonium salts of 4-aminopyrazole derivs. had been shown (*C. A.* **9**, 1173) to be more stable than those of 5-aminopyrazoles contg. a Ph substituent. The stability of the diazonium chloride of 1-phenyl-3,5-dimethyl-4-aminopyrazole (I) showed this stability to be a function of the position of the NH_2 group and not to be due to the presence of the substituent Ph group. From the study of pyrazolediazonium derivs. it appears that the essential factors for diazotization are the grouping $\diagup\!\!\diagdown CNH_2$ and other foci of unsatn. I was prepd. by condensing isonitrosoacetylacetone with $PhNHNH_2.HCl$ (*Ann* **325**, 129–95) and reducing the resulting nitrosopyrazole with Sn and HCl. I forms a yellow, dibasic chloroplatinate, an unstable red ppt. with $AuCl_3$ and a Bz deriv., m. 153–4°. It also condenses with BzH to give a benzylidene deriv., m. 90–1°. 4-Amino-3,5-dimethylpyrazole gives characteristic colors with phenols in alk. soln. and its diazonium chloride forms a triazo deriv. with NaN_3 but I fails to give these reactions. Treatment of an acid soln. of I in dil. EtOH with $EtNO_2$ yielded the diazonium chloride (II) of I which probably has the structure

It is a white powder, very stable under ordinary conditions, and heated at 100° for 6 hrs it loses only about 20% of its coupling power. With KCN in acid soln. it loses its coupling power and yields a yellow ppt. II couples with $PhNMe_2$, $PhNEt_2$, *p*-$MeC_6H_4NH_2$, α-$C_{10}H_7NH_2$, and β-$C_{10}H_7NH_2$ (orange-yellow crystals, m. 195–6°) to give colored azo derivs.; with β-$C_{10}H_7OH$ it gives a red compd. m. 189–90°; with 8,3,6- and 2,6,8-$C_{10}H_4(OH)(SO_3H)_2$ it gives sol. red dyes; with 1,8,3,6-$C_{10}H_4(OH)_2(SO_3H)_2$ it gives a sol. purple dye; and with *m*-$C_6H_4(NH_2)_2$ it gives a red azo chrysoidine color. II also couples with Ac_2CH_2 to give dark yellow crystals, m. 84–5°, and with $AcCH_2CO_2Et$ to give yellow crystals, m. 115–6°. These compds. with diketones are sol. in the usual org. solvents but not in alkalies and may possess one of the following 3 structures: (Pyr = pyrazole nucleus) Pyr.N:N-CH(COR')COR, Pyr.N:NC(COR'):C(OH)R, Pyr.NHN:C(COR')COR.

C. H. Peet

Organic catalysts. V. Investigation of the cleavage of α-keto acids. Wolfgang Langenbeck, Rudolf Hutschenreuter and Robert Jüttemann. *Ann.* **485**, 53–61 (1931); cf. *C. A.* **24**, 4285.—The following study was made in an effort to det. the cause of the retarding action of aldehydes upon the catalytic cleavage of α-keto acids. $BzCO_2H.PhNH_2$ (2 g.) and 0.1 g $BzCO_2H$ (I) or 5 drops BzH, heated at 250° for 5 min., give 0.05 g. of *pentaphenyldihydroimidazole* (II), $C_{33}H_{28}N_2$, pale yellow, decomps. between 400–50°, a part of the compd. being sublimed; it crystallizes with 2 mols. H_2O, which are not lost at 150° *in vacuo*. II also results in 0.5 g. yield from 5 g. desyl chloride

and 2 g. $PhNH_2$ at 140–50° for 1 hr., removing the $PhNH_2$.HCl and again heating with BzH at 150–60° for 1 hr. PhC(:NPh)CHPhNHPh is probably an intermediate product, since with BzH at 150–60° for 1 hr., this yields 72% of II. *Perchlorate* of II, needles from boiling AcOH, decomps. when heated; *periodide*, brown leaflets, becoming colorless at 250°, losing I; *perbromide*, needles; *HCl salt*, needles, decompg. above 300°; with KI this gives the difficultly sol. HI salt. II does not give a cryst. oxidation product with O_3 in AcOH. CrO_3-AcOH gives a chromate but has no oxidizing action. II is probably formed in a similar manner in the catalytic cleavage of I by $PhNH_2$. β-Aminooxindole forms a *picrate* (III), yellow, darkens at 150°. Further expts. on the action of $PhNHCH_2CO_2H$, $BzCO_2K$, p-$MeOC_6H_4NHCH_2CO_2H$, m-$O_2NC_6H_4NHCH_2CO_2H$ and III on I are reported. C. J. West

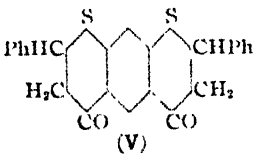
Absorption spectra and constitution of azoxy derivatives and analogous compounds. L. Szegö and P. Ostinelli. *Atti III congresso naz. chim. pura applicata* 1930, 395–401.—The ultra-violet absorption spectra of alc. solns. of *desoxybenzoin* and the following derivs. have been detd.: *α-p-nitro*, *α-p-amino*, *α-* and *β-p-hydroxy*, *α-* and *β-p-methyl* and *β-p-chloro* (α-form is $C_6H_5COCH_2C_6H_4R$, β-form is $C_6H_5CH_2COC_6H_4R$). *β-p-Chlorodesoxybenzoin* is prepd. as follows: phenylacetyl chloride is condensed with chlorobenzene (I) in the presence of $AlCl_3$ by heating 2 hrs. on a water bath and 2 hrs. at 120°. The excess of (I) is distd. off and the mass decompd. with H_2O and then extd. with ether. This was distd. off and the residue treated with animal charcoal in 95% alc. It was pptd. with H_2O and recrystd. from ether; it m. 102°. The oxime was prepd. by heating an alc. soln. of the ketone with the equiv. quantity of hydroxylamine-HCl and Na_2CO_3 in H_2O. The alc. was evapd. and the product, washed with H_2O dissolved in alc. and pptd. with H_2O, m. 117°. The α-isomers and non-substituted desoxybenzoin behave alike but give a different type of absorption curve from the β-isomers. J. B. A.

Absorption spectra and the constitution of the desoxybenzoin series. L. Szegö and P. Ostinelli. *Gazz. chim. ital.* 60, 677–88(1930).—In a previous paper (cf. preceding abstr.) it was shown that substituents have different effects on the absorption spectra of desoxybenzoin compds. from their effect on those of azoxy compds. (cf. S., *C. A.* **23**, 4406). In the latter the influence of the substituent in the nucleus on the absorption power is less when it is nearer the azoxy group ($XC_6H_4N(:O):NPh$) than when it is in the farther position ($XC_6H_4N:N(:O)Ph$). On the contrary, absorption is greater in $XC_6H_4COCH_2Ph$ compds. than in $XC_6H_4CH_2COPh$ compds. The behavior of the azoxy compds. is explained by the fact that double-bonded O in the azoxy group dampens the effect of the substituent by partial valences, resulting in a more stable condition in the substituted nucleus. This hypothesis is supported by the great similarity between azo and $XC_6H_4N:N(:O)Ph$ compds. The opposite effect in the desoxybenzoin series does not permit a similar hypothesis, so further expts. were carried out with isomers of other desoxybenzoins (substituted in both nuclei), most of which are new. p-$ClC_6H_4CH_2CO_2H$ cannot be prepd. satisfactorily by the method of Petrenko-Kritschenko (cf. *Ber.* **25**, 1240(1892)), so it was prepd. by sapon. of p-$ClC_6H_4CH_2CN$. It was then transformed into p-$ClC_6H_4CH_2CO_2Cl$ (I). The latter condensed with C_6H_6 in the presence of $AlCl_3$ yields p-$ClC_6H_4CH_2COPh$ (II). p-$MeC_6H_4CH_2Cl$ condensed with PhCl in the presence of $AlCl_3$, heated several hrs. at 130°, excess PhCl distd. off, the residue decompd. with water, washed with HCl, then with Na_2CO_3, extd. with Et_2O, the residue dissolved in EtOH, purified with animal charcoal, pptd. with water and crystd. repeatedly from a mixt. of petr. ether and C_6H_6, yields *4-chloro-4'-methyldesoxybenzoin*, p-$MeC_6H_4CH_2COC_6H_3Cl$-p (III), m. 123°. Similarly, condensation of I with PhMe yields *4-methyl-4'-chlorodesoxybenzoin* (IV), m. 113°. $MeC_6H_4CH_2CO_2H$, PhOH and $ZnCl_2$, heated 0.5 hr. at 200°, dissolved in C_6H_6 and a little water, washed free of $ZnCl_2$ by HCl, made alk. with Na_2CO_3, acidified with HCl (d. 1.19), the ppt. purified with animal charcoal and recrystd. from dil. EtOH, yields *4-hydroxy-4'-methyldesoxybenzoin* (V), m. 162°. p-$O_2NC_6H_4CH_2Cl$, PhMe in CS_2 and $AlCl_3$ heated 3 hrs. on a water bath, the CS_2 and PhMe distd., the residue decompd. by water, washed with HCl and Na_2CO_3, crystd. from dil. EtOH, reduced with Sn and HCl in EtOH, made alk., extd. with Et_2O, the ext. evapd., the residue recrystd. from dil. EtOH, diazotized in H_2SO_4 and the product recrystd. from hot water, yields *4-methyl-4'-hydroxydesoxybenzoin* (VI), m. 146°. *4-Hydroxy-3-methyldesoxybenzoin* (VII) was prepd. by the method of Blau (*Monatsh.* **26**, 1149(1905)). $PhCH_2Ac$ was prepd. by dry-distg. a mixt. of $Ca(OAc)_2$ and $(PhCH_2CO)_2Ca$ (2 parts). The measurements of the absorption consts. in the ultra-violet range were carried out by the method already described (*loc. cit.*). The ketones were examd. in hexane (optically pure) (cf. Wolf and Herold, *C. A.* **23**, 5416) and the desoxybenzoins in EtOH (the absorption curves with EtOH and with hexane are identical). The results are tabulated

in complete detail. In all cases the phenomena were similar to those previously described, *viz.*, the max. absorptions of the β-isomers of *p*-chloro-, *p*-methyl- and *p*-hydroxydesoxybenzoin are displaced toward lower frequencies with respect to their α-isomers. The displacement between the 2 OH-isomers is greater than between the 2 Cl derivs., which in turn show greater differences in the isomers with a nuclear Me group. The weak absorption band of the β-isomers of hydroxy-, methyl- and chlorodesoxybenzoin, and to which has been attributed the color, disappears after complete purification. Thus, β hydroxydesoxybenzoin, described by Weisl (*Monatsh.* **26**, 984 (1905)) as orange-red, is colorless when highly purified. In the compds. with substituents in each nucleus, as in the methylhydroxy derivs., V has a great max. displacement compared with that of VI and the displacement increases still more when both substituents are in the nucleus on the CO group, *viz.*, in VII. Similar relations are found in the Me-Cl derivs., where the effect of the Cl prevails over that of the Me group, as with the compds. contg. a single substituent. Therefore the increase in light absorption resulting from proximity to the CO group is not unusual but is found in all compds. The CO group has an effect wholly apart from a dampening of the substituent and its nucleus. The proximity of CO to unsatd. bonds greatly increases the absorption power (cf. Bielecki and Henri, *C. A.* **8**, 691), and even the C_6H_5 nucleus with its conjugated double bonds has a similar influence (cf. v. Auwers, *C. A.* **9**, 1459; **13**, 432-3). Measurements of ketones of the PhCOEt and $PhCH_2COMe$ type show how profound is the influence of the position of CO with respect to the C_6H_5 nucleus. In every case there is an increase in the power of extinction, beginning with compds. with the CO directly on the C_6H_5 nucleus. This effect is much more intense in the ketones than in the desoxybenzoins, since in the ketones the distance between 2 centers of oscillation has a greater influence than in the desoxybenzoins, in which the displacement of frequency indicates only the variations in the state of satn. of 1 C_6H_5 nucleus with respect to the other. The joint effect of the 2 centers of oscillation with unsatd. character leads to greater optical exaltation. In desoxybenzoins the CO group has a lower degree of satn. than the neighboring CH_2 group, while the azoxy -N(:O)= group corresponds to nitric N and involves a greater satn. of the same N atom. Therefore, of the 2 N atoms in the azoxy compds., the quinquevalent N is in the higher state of satn. The proximity of an O or quinquevalent N atom should not have a depressing effect on the substituted nucleus, while the tervalent N has an excitant effect like the CO group, which induces an increase in the absorption power by the reciprocal influence of the 2 unsatd. groups. A comparison of the absorption spectra of the simplest aromatic derivs. having their N in the form of NO_2, NO or NH_2 groups confirms these deductions. The same reasoning may be extended to diazo compds. According to Angeli (*C. A.* **2**, 2991) these are not simply stereoisomers. Cambi (*C. A.* **21**, 3895) on the contrary gives the structures $(RN(:O).N)'K^+$ and $(RN.N.O)'K^+$ to the normal and isodiazotates, resp. Cambi and Szego (*C. A.* **23**, 337) have shown that normal diazotates have continuous absorption spectra with low coeffs. of extinction, whereas the iso derivs. have a max. absorption in the ultra-violet. Based on the formula above of normal diazotates, the quinquevalent N carrying the O is next to the nucleus, while in iso compds. the O is on the terminal N. The optical behavior agrees perfectly with the hypothesis:

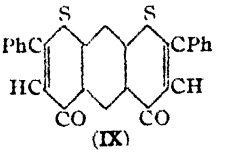
$\{p\text{-}XC_6H_4N(:O):N\}'$	$\{p\text{-}XC_6H_4N.N.O\}'$
(normal)	(iso)
smaller absorption	greater absorption

Both in the aromatic ketones with the CH_2CO chain and in azoxy derivs. and diazotates, the variation in absorption power for ultra-violet light depends upon the distance of the 2 centers of oscillation with the lower degree of satn., and it increases when the 2 centers are closer together. C. C. Davis



Spectrography of the flavone series. III. The constitution of wogonin. Shizuo Hattori. *Acta Phytochim.* **5**, 99-116(1930); cf. *C. A.* **22**, 3661.—Wogonin (I) is present in small amounts in the roots of *Scutellaria baicalensis* Georgi (*Labiatae*) while baicalin forms the much larger part. I is extd. with benzene and recrystd. from 80% alc., forming yellow needles, m. 201°. The analyses correspond with the formula $C_{16}H_{12}O_5$; it contains two HO and one MeO group. One of the HO groups is methylated by CH_2N_2, forming a Me ether, m. 183°, which gives a brown color with $FeCl_3$. This behavior indicates a free HO group in the *o*-position to the C:O group. Methylation with Me_2SO_4 and alkali yields a di-Me ether, m. 167-8° (II), which does not give a color with $FeCl_3$. Upon hydrolysis with 20% NaOH, PhCOMe and BzOH are obtained. Upon boiling with HI (d. 1.7), I is demethylated with the formation of a deep yellow

product, m. 226–7°, which has three HO groups, probably in the 5,7,8-positions, and the formula $C_{18}H_{10}O_8$. Comparison of the absorption spectra of acetylwogonin with 8-hydroxy- and 8-methoxyflavone showed an analogy from which it is concluded that I has the MeO group in position 8. The structure was finally detd. by synthesizing 5,7,8-trimethoxyflavone and comparing it directly with II. The reaction of $AlCl_3$ with 2,3,4,6-$(MeO)_4C_6HCOMe$ yielded a substance, m. 112–3° (III), identical with 1 of the 4 substances obtained by Bargellini and later by Chapman, Perkin and Robinson (*C. A.* **22**, 961) contg. one HO and three MeO groups. The HO group gave a $FeCl_3$ reaction indicative of being in the *o*-position to the C:O group (2 or 6). Fusion of III with Bz_2O and BzONa yielded a flavone, m. 167–8°, identical with II and not with the known 5,6,7-trimethoxyflavone. I, therefore, is 5,7-dihydroxy-8-methoxyflavone. Absorption spectra are given of 8-methoxyflavone, acetyl-, mono- and dimethylwogonin and wogonin and 5,7,8-trihydroxyflavone. E. GEBAUER-FÜLNEGG



Diflavone group. V. *m*-Methoxybenzaldehyde and diacetoresorcinol. ELIZABETH M. RYAN AND HUGH RYAN. *Proc. Roy. Irish Acad.* **39B**, 425–33(1930); cf. *C. A.* **8**, 1107; **9**, 2229; **10**, 1506, 1848–9, 2209, 2577.—The diacetate of tetrabromodibenzylidenediacetoresorcinol (I) yielded diflavone upon treatment with alc. KOH, but the corresponding anisylidene and veratrylidene compds. yielded dicoumaranones The type of ring formed must depend upon the relative lability of the α- and β-Br atoms and it appeared that a *p*-MeO group increased the lability of the β-Br atoms According to the theory of induced alternate polarities, a *m*-MeO group should have a less marked influence so the *m*-MeO homolog (II) of I was prepd. by condensing di acetoresorcinol with *m*-$MeOC_6H_4CHO$, followed by acetylation and bromination The principal product was the corresponding 3′,3″-dimethoxydicoumaranone (III) but the absence of a diflavone was not proved. Di-*m*-methoxybenzylidenediaceto resorcinol di-Me ether, slightly sol. in EtOH, Et_2O, sol. in PhH, Me_2CO, $CHCl_3$, m. 157–8°, gave a dibromide, m. 213° (decompn.), a tetrabromide (purity uncertain), m 176° (decompn.), and a pentabromide (purity uncertain), m. 186° (decompn.). Di-*m* methoxybenzylidenediacetoresorcinol (IV) was insol. in H_2O and petroleum ether, slightly sol. in EtOH and Et_2O, sol. in dil. KOH, $CHCl_3$, Me_2CO and PhH and m. 157° IV prepd. in EtOH was orange-yellow; better yields were obtained in MeOH but the color was light yellow. The resp. colors of these chromoisomers remained unchanged after repeated recrystns., their m. ps. and mixed m. ps. were the same and they formed the same diacetate, m. 122°. II could not be crystd. III, crystd. from C_5H_5N, m 277–9° (decompn.). Dipiperonylidenedi-*m*-methoxydiflavanone, prepd. by treating a mixt. of 2 g. of IV and 5 g. of piperonal in 60 cc. of $CHCl_3$ with 40 cc. alc. HCl, m 245°. Similarly BzH condensed with IV to give dibenzylidenedi-*m*-methoxyflavanone, m. 249–50°. C. H. PEET

Thiophenols. Dithioflavone and linear dithioflavanone. C. FINZI, G. VENTURINI AND L. SARTINI. *Gazz. chim. ital.* **60**, 798–811(1930).—Previous expts. which dealt with compds. contg. 2 heterocyclic sulfurated nuclei arranged symmetrically in the C_6H_6 nucleus and in which diketothiazine, dithiochromanone and dithioxanthone were prepd. (cf. *C. A.* **20**, 1992; **21**, 740; **22**, 4465), were continued in the present work by the prepn. of dithio derivs. It was necessary in this connection to study the behavior of polythiophenols with unsatd. compds. of the C_2H_2 and C_3H_4 series. Dithioresorcinol (I) was chosen because of the ease of prepn. of its isomers and because from it could be obtained derivs. contg. 2 sym heterocyclic sulfurated groups on the central C_6H_4 nucleus. It was found that I forms addn. products with C_2H_2 and C_3H_4 derivs., each group adding to a double or to a triple bond. The addn. of $PhCH:CHCO_2H$ (II) to I can be accomplished by heating I, II (2 mols.) and glacial AcOH, satd. with HBr at 100° in a sealed tube for several hrs., steam-distg. (to remove excess I), and washing the residue with boiling water, but the yield is very small. A much higher yield is obtained by heating I, $PhCHBrCH_2CO_2H$ (cf. *Ber.* **11**, 1221) (3.5 parts) and AcOH satd. with HBr (17 parts) at 100° in a sealed tube for 5–6 hrs., pouring into water, steam distg., and washing the residue with boiling water. The product is ***m*-phenylenedithio-β-hydrocinnamic acid***, *m*-$C_6H_4[SCH(CH_2CO_2H)Ph]_2$ (III), pitch which cannot be crystd., sol. in aq. alk. hydroxides and carbonates. III (5 g.) in aq. Na_2CO_3, oxidized with aq $KMnO_4$ (5 g.) (the reaction mixt. being partially neutralized with dil. H_2SO_4 during the oxidation), filtered, washed with boiling water, the filtrate concd., acidified with H_2SO_4 and the ppt. recrystd. from EtOH, yields ***m*-phenylenedisulfonyl-β-hydrocinnamic acid***, *m*-$C_6H_4[SO_2CH(CH_2CO_2H)Ph]_2$ (IV), m. 192°. III and $POCl_3$ (15 parts), heated on a water bath for a long time (with vigorous agitation), poured into ice-water (before the reaction product has become too thick), the sepd. green-brown oil allowed to solidify, digested with warm, dil. Na_2CO_3, extd. with boiling EtOH, the ext. concd., and the ppt.

purified by repeated crystns. from EtOH, yield *dithioflavanone* (V), greenish yellow, softens around 65–70°, semifuses at 85–90°, completely fused at 120–5°, gives intense carmine-red solns. in concd. H_2SO_4 (test of thioflavanone group). IV is also formed from III and PCl_5 with anhyd. $AlCl_3$ under the same conditions. I (5 g.) in anhyd. PhMe (40 cc.) and Na (2 g.), boiled several hrs., with frequent agitation, the unaltered Na carefully removed, PhC : CCO_2Et (12.5 g.) in PhMe added, with vigorous agitation, let stand several hrs., water added, acidified with dil. H_2SO_4, extd. with Et_2O, the PhMe-Et_2O ext. extd. with aq. KOH, the PhMe-Et_2O residual soln. dried with $CaCl_2$, and the solvents distd. *in vacuo*, leaves a residue of straw-yellow oil which is a mixt. of *Et m-phenylene-α-dithiocinnamate* and *Et m-phenylene-β-dithiocinnamate*, which could not be crystd. This mixt., sapond. by refluxing with alc. KOH (4 g.) for 2 hrs., dild. with water (equal vol.), the EtOH distd., the aq. residue extd. with Et_2O (to remove traces of styrene formed by decompn. of the acid), the aq. residue acidified with dil. H_2SO_4, the ppt. (mixt. of α- and β-acids) extd. with warm EtOH, and the ext. evapd., leaves *m-phenylene-α-dithiocinnamic acid*, *m*-$C_6H_4[SC(:CHPh)CO_2H]_2$ (VI), oil. The residue from the EtOH extn., recrystd. from boiling AcOH, yields *m-phenylene-β-dithiocinnamic acid*, *m*-$C_6H_4[SC(:CHCO_2H)Ph]_2$ (VII), pale yellowish, m. 224°. VII heated above its m. p. evolves CO_2 and leaves *m-phenylenedithiostyrene*, *m*-$C_6H_4[SC(:CH_2)Ph]_2$ (VIII), oil, cannot be crystd. Also I (3 g.) in anhyd. PhMe and Na (1 g.), refluxed for a long time, cooled, the excess Na removed, agitated with HC : CPh (4.5 g.) in PhMe, let stand, a little water added, acidified with dil. H_2SO_4, extd. with Et_2O, the PhMe-Et_2O ext. extd. with aq. NaOH, the residue washed with water, dried with $CaCl_2$, and the Et_2O and PhMe distd., leaves VIII. Na-Hg (30 g. of 3%) added slowly to VII (1.5 g.) suspended in water, acidified with dil. H_2SO_4, forms an oil which cannot be crystd. This oil (1 g.) in aq. Na_2CO_3, oxidized with concd. $KMnO_4$ (calcd. quantity), filtered, washed with boiling water, the filtrate concd., acidified with dil. H_2SO_4, and the ppt. recrystd. from boiling EtOH, yields IV. PCl_5 (1.95 g.) and then anhyd. $AlCl_3$ (4.5 g.) added with continuous agitation to VII (2 g.) suspended in anhyd. C_6H_6 (20 cc.), warmed gently to complete the reaction, let stand with frequent agitation, cooled, ice added, filtered, the residue washed with water, digested in dil. aq. Na_2CO_3 and the residue recrystd. twice from boiling C_6H_6, yields *dithioflavone* (IX), pale lemon-yellow, m. 255–6°, gives a yellow soln. in concd. H_2SO_4. VII (1 g.), agitated with concd.

(V)

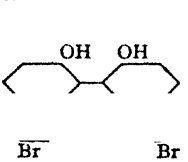
(IX)

H_2SO_4 (5 cc.) (cooling), heated at 50–60° for some time, poured into water, filtered, the residue washed with water, digested in aq. Na_2CO_3 and recrystd. from C_6H_6, also yields IX. VI in oil form (*loc. cit.*) could not be made to cryst. from any solvent, but by acidification of its soln. in aq. Na_2CO_3 it seps. in the solid state, though not cryst. The only means of purification is to dissolve it in dil. Na_2CO_3, filter, reppt. with dil. H_2SO_4 and repeat this operation. Thus prepd., VI is a yellowish amorphous solid, which in time becomes compact and friable. It has no sharp m. p., but softens around 70° and at 73° it becomes a frothy liquid. Hydrogenated with Na-Hg and then oxidized with $KMnO_4$, VI partially decomps., but does not yield crystallizable products. It is decompd. by concd. H_2SO_4, with evolution of SO_2 and BzH, in this case the H_2SO_4 not having the dehydrating action which occurs in the formation of the thiochromanone and thioxanthone nuclei, but rather an oxidizing action which results in cleavage of the double bond. VI, heated at 180–90° until CO_2 is no longer evolved, cooled, washed with aq. Na_2CO_3 (to remove unaltered VI), suspended in EtOH, reduced with a great excess of Na-Hg, the Hg sepd., filtered, the filtrate partially evapd., dild. with a large vol. of water, let stand, yields a light yellow oil which cannot be crystd. and which is *m-phenylenedithioethylbenzene*, *m*-$C_6H_4(SCH_2CH_2Ph)_2$ (X), does not distil up to 300° *in vacuo*. Aq. NaOH (1.2 g.) and then $PhCH_2CH_2Cl$ (4 g.) added to alc. I (2 g.), refluxed 0.5 hr., the EtOH distd., the residue extd. with Et_2O, the ext. dried with $CaCl_2$, and the Et_2O evapd., yields X. This confirms the constitution of VI and VII, for in the reaction between I and PhC : CCO_2Et, the addn. of the thiophenol groups on the C_2H_2 bond takes place in 2 ways: union of the S to the α-C and to the β-C atom of the PhC : CCO_2H, giving rise to 2 groupings: PhC(:CHCO$_2$H) S— and PhCH:C-(CO$_2$H).S—.

C. C. DAVIS

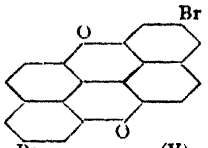
The position of the glucuronic acid linkage in baicalin. KEITA SHIBATA AND SHIZUO HATTORI *Acta Phytochim.* **5**, 117–8(1930).—In baicalin (I), a glucuronic acid deriv. of baicalein (5,6,7-trihydroxyflavone), the glucuronic acid radical (II) can be linked only in positions 6 or 7 since on methylation only 1 mono-Me ether can be obtained which gives a violet-brown color reaction with $FeCl_3$, showing that the HO group in position 5 and ortho to the C:O group is still free. Position 7 for the linkage with II is likely on account of the green color reaction of I with $FeCl_3$ in analogy with the 5,6-dihydroxyflavone. Furthermore cobalti pentammine salts, which are known to oxidize vicinal phenolic derivs., attack alc. solns. of I easily, forming ppts. after a color change. E. GEBAUER-FUELNEGG

Quinoline compounds containing arsenic. II. Synthesis of 6-methoxyquinoline derivatives of aminophenylarsonic acids by the use of 4-bromo-6-methoxy-2-methylquinoline. ROBERT H. SLATER. *J. Chem. Soc.* **1931**, 107–18; cf. *C. A.* **24**, 4039.—An improved method is given for the prepn. of 4-hydroxy-6-methoxy-2-methylquinoline (61% yield); $POBr_3$ gives the *4-Br deriv.* (I), m. 117–8°; the AcOH and dil. HNO_3 solns. exhibit a blue fluorescence and a dil. H_2SO_4 soln. a greenish blue fluorescence, changing to violet on dilu. Heating a mixt. of 8.5 g. I, 5.4 g. *o*-$H_2NC_6H_4AsO_3H$, 70 cc. AmOH, 16 g. K_2CO_3 and a trace of Cu bronze and I at 130–40° for 22 hrs. gives 5.9 g. *o-6'-methoxy-2'-methyl-4'-quinolylaminophenylarsonic acid* (II), m. 302–3° (decompn.); isoelectric pt. p_H 7.3; crystals from dil. AcOH. A colloidal soln. does not give a color with 0.001 *N* I; addn. of a few drops of concd. HCl gives a brilliant violet color, which disappears on addn. of more HCl; the warm concd. H_2SO_4 soln. exhibits a blue fluorescence. Various salts are qual. described. Reduction of II in EtOH-HCl contg. a trace of I with SO_2 gives *12-chloro-7-methoxy-11-methyl-5,12-dihydroquinbenzarsazine* (III), pale yellow, m. 245–7° (decompn.). Oxidation of III with H_2O_2 in AcOH gives *7-methoxy-11-methylquinbenzarsazinic acid*, pale yellow, does not m. 310°; various solns. exhibit a blue fluorescence; salts are qualitatively described. $POCl_3$ below 80° gives the *chloride*, pale yellow, m. 165–7°; the dil. aq. NaOH soln. exhibits a bright blue fluorescence, I (5 g.) and *o*-tolidine (10 g.), heated 9 hrs. at 140–50°, give 7.2 g. of *4-o-tolidino-6-methoxy-2-methoxyquinoline* (IV), pale yellow, crystg. with EtOH, m. 152°; heating 5 hrs. at 100° gives the anhyd. compd., m. 199–200°; the diazo chloride gives a blood-red azo dye with alk. β-$C_{10}H_7OH$; a dil. soln. in EtOH or AcOH gives a reddish brown color with 0.001 *N* I. *Ac deriv.*, m. 182–3°. The diazo compd from IV, pale orange, with Na_3AsO_3 gives *4',6"-methoxy-2"-methyl-4"-quinolylamino-3,3'-dimethyldiphenylylarsonic acid*, m. 304–5°; the warm concd. H_2SO_4 soln. shows a light blue fluorescence, which disappears on dilu. *4-o-Dianisidino-6-methoxy-2-methylquinoline* (V), pale yellow, m. 195–6°, was best prepd. by heating the components at 140° and 10–5 mm.; a dil. EtOH soln. gives a red color with 0.001 *N* I. *Ac deriv.*, crystals with H_2O, m. 140° and then 200–1°; the C_6H_6 soln. exhibits a greenish blue fluorescence; the EtOH soln. gives a brilliant blue color with 0.001 *N* I, while the AcOH soln. gives an intense red color. The Bart reaction with V gives *4',6"-methoxy-2-methyl-4"-quinolylamino-3,3'-dimethoxydiphenylylarsonic acid*, pale grey, m. 243.5° (decompn.); the dil. AcOH soln. gives a dark brown ppt. with 0.001 *N* I. I and (*p*-$H_2NC_6H_4)_2CH_2$, heated at 135–40° and 10–5 mm., give *p-6-methoxy-2-methyl-4-quinolylamino-p'-aminodiphenylmethane*, pale yellow, crystals with 1 mol. H_2O, m. 135–45°; the Bart reaction gives *p-6-methoxy-2-methyl-4-quinolylaminodiphenylmethane-p'-arsonic acid*, pale yellow, chars at 300°; a soln. in concd. H_2SO_4 gives a brilliant purplish blue fluorescence which is destroyed on dilu. with H_2O. *4-Anilino-6-methoxy-2-methylquinoline*, m. 208–9°; *HCl salt*, does not m. 310°. The chemotherapeutic tests will be published elsewhere. C. J. WEST



β-Diketones in ring formation. II. UMAPRASANNA BASU. *J. Indian Chem. Soc.* **7**, 815–24(1930); cf. *C. A.* **24**, 5752.—Bz_2CH_2 (I), supposedly 96% enolic, gives 45% of *3-cyano-4,6-diphenyl-2-pyridone*, when condensed with $CNCH_2CONH_2$ (IV). To exam. the influence of the adjacent substituent in the enolic modification in the course of such condensations, IV has been condensed with I, *p*-$MeC_6H_4COCH_2Bz$ (II) and $CH_2(COEt)_2$ (III). I condensed with IV in the presence of NaOEt, gave 5–20% of $\overline{NH.CO.C(CN):CPh.CH:CPh}$, m. 320°. By using Et_2NH as a condensing agent, 55–70% was obtained, a 50% excess of IV improving the yield. The condensation of IV with II by the aid of Et_2NH gave 34% of $\overline{NH.CO.C(CN):CPh.CH:CC_6H_4Me}$, m. 267° (which on heating with H_2SO_4 evolved CO_2 and formed $\overline{NH.CO.CH:CPh.CH:CC_6H_4Me}$, m. 226–8°), and 17% of $\overline{NH.CO.C(CN):C}$

$(C_6H_4Me).CH:CPh$, m. 311–2°, hydrolyzed to $NH.CO.CH:C(C_6H_4Me).CH:CPh$, m. 237–9°. According to B. the main crop is derived from the $PhC(OH):CHCOC_6H_4Me$ modification owing to the greater inhibiting effect of the β-tolyl group in the $MeC_6H_4C(OH):CHCOPh$ form. That the reaction had taken place only through the enolic phase was evident by the isolation of only $NH\ CO.C(CN):CPh.CH:CC_6H_4Me$ from the condensation of IV with $PhC(OMe):CHCOC_6H_4Me$. $NH\ CO\ C(CN):CEt.CH:CEt$, m. 186°, the condensation product of III and IV, was heated with concd. HCl for 3 hrs. at 150° and hydrolyzed to $NH.CO.CH:CEt.CH:CEt$, m. 61–2°. The influence of substituents on the reactivity of the CH_2 group of IV was studied by condensations involving the use of $CH_2(CONH_2)_2$ (VI) and $CH_2(CN)_2$ (VII). Ac_2CH_2 (VIII) and VI formed $NH.CO.C(CONH_2):CMe.CH:CMe$, m. 224–5° (which was hydrolyzed with concd. HCl to *ψ-lutidostyril*, m. 179–80°), whereas $ClCH_2CONH_2$ and $PhCH_2CONH_2$ could not be condensed with VIII. A mixt. of VII and VIII with the addn. of a little Et_2NH gave 77% of *3-cyano-ψ-lutidostyril*, $NH.CO\ C(CN):CMe.CH:CMe$, m. 289°. With $CNCH_2CO_2Et$ and VII, resp., $BzCH_2Ac$ gave $NH.CO.C(CO_2Et):CMe.CH:CPh$, m. 216–7°, and $NH.CO.C(CN):CMe.CH:CPh$, m. 310°.



C. R. ADDINALL

Derivatives of dinaphthylene dioxide. A. CORBELLINI AND PASTURINI *Gazz. chim. ital.* **60**, 843–61(1930).—The expts. continue the previous ones (cf. C. and Vietti, *C. A.* **23**, 3458). Concd. β-dinaphthol (I) in AcOH and Br (calcd. quantity) in AcOH, heated on a water bath, cooled, the ppt. removed, the mother liquor concd. until further crystn. is complete, and the combined products recrystd. from C_6H_6 or $CHCl_3$, yield almost 100% of dibromo-β-dinaphthol (II), m. 202–3° (which is far from the 155° obtained by Fosse (cf. *Bull. soc. chim.* [3], **21**, 657), when prepd. in the same way). Methylation of alk. II by Me_2SO_4 with crystn. from PhCl yields the *di-Me deriv.*, $C_{22}H_{16}O_2Br_2$, m. 239.5° (not cor.). To det. the position of the 2 Br atoms the oxidation products of II were studied. With a compd. of this complexity, the products vary with the nature and quantity of the oxidizing agent. II (15 g.) in AcOH, oxidized with CrO_3 (15 g.) on a water bath, when the reaction is completed heated to boiling, concd., dild. with water, acidified with H_2SO_4, the ppt. dissolved in dil. Na_2CO_3, oxidized with $KMnO_4$ (at first cold, then on a water bath), the excess $KMnO_4$ reduced with EtOH, filtered, the filtrate concd. on a water bath, acidified with HCl, extd. with Et_2O, the ext. evapd. almost to dryness, $CHCl_3$ added, the ppt. sublimed *in vacuo* around 150° and the sublimate recrystd. from abs. Et_2O, yields 4-bromophthalic acid (III), m. 105–7° (cf. *Ber.* **20**, 1017(1887); Stephens, *C. A.* **16**, 253). Oxidation in the same way with $KMnO_4$ of the product obtained by extg. with Et_2O the dild. AcOH soln., or that obtained by sepn. on long standing, yields more III. Alk. II (5 g.), oxidized with dil. aq. $KMnO_4$ (8.35 g.) first cold and then on a water bath, the excess $KMnO_4$ reduced with EtOH, filtered hot, the residue washed thoroughly with boiling water (to ext. the slightly sol. K salt), the combined filtrates acidified with HCl and the ppt. recrystd. from $PhNO_2$, yields *2-[2-hydroxy-6-bromo-1-naphthoyl]-5-bromobenzoic acid* (IV), pale brown-yellow, m. 346° (not cor.). The *Na salt* of IV (0.2 g.) and fused KOH (1 g.), kept at a min. temp. until the product is completely sol. in water, dissolved in water and aq. HCl added, ppt. an unidentified *compd.*, does not m. up to 300°, contains no Br, sol. in aq. Na_2CO_3. This reaction with KOH was carried out with the purpose of decompg. IV into III and bromo-2-naphthol, a decompn. which takes place easily with 2-[2-hydroxynaphthoyl]benzoic acid (cf. Walder, *Ber.* **16**, 299(1883)), but in the present case KOH probably merely replaced 2 Br atoms by OH groups, without rupture of the mol. Boiling aq. 6-bromo-2-naphthol (m. 128.5°; cf. Franzen and Stäuble, *C. A.* **16**, 1945) (0.25 g. in 150 cc.), oxidized with boiling aq. $FeCl_3$ (0.3 g.), boiled for some time, filtered, the residue washed with dil. HCl and recrystd. from C_6H_6, yields *2,2'-dihydroxy-6,6'-dibromo-1,1'-dinaphthyl*, m. 203°, mixed with II it melts at the same temp., establishing the constitution of II. II cyclicized by CuO according to the method already used for I (cf. C. and Vietti, *loc. cit.*), the product extd. with PhCl, the ext. concd. and the ppt. sepd. by fractional crystn. from $PhNO_2$, yields 2 products: (1) a less sol. *compd.* $C_{20}H_8O_2Br_2$ (V), m. 361–2° (not cor.), yellow, corre-

sponds in compn. to a di-Br deriv. of dinaphthylene dioxide, sublimes unaltered *in vacuo*, and (2) a more sol. unidentified *compd.* $C_{40}H_{16}O_4Br_2$, red, m. 421–2°, sublimes unaltered *in vacuo*.

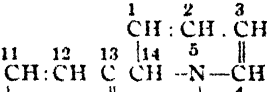
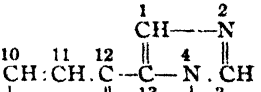
C. C. DAVIS



Quinoline compounds. II. Some derivatives of 4-phenyl-2-methylquinoline. UPENDRA N. BRAHMACHARI AND TARAPADA BHATTACHARYYA. *J. Indian Chem. Soc.* **7**, 831–4(1930); cf. *C. A.* **24**, 5875.—The enhanced toxicity of 4-phenyl-2-methylquinoline toward protozoa compared to that of quinoline induced B. and B. to synthesize *6-nitro-4-phenyl-2-methylquinoline* (I) and *8-nitro-4-phenyl-2-methylquinoline* (II). A mixt. of 50 cc. AcPh and 30 cc. $(AcH)_2$, cooled in ice and satd. with HCl was allowed to stand for 48 hrs. After resatn. with HCl, and standing for 24 hrs. the mixt. was added to 58 g. of p-$NO_2C_6H_4NH_2$ and 90 cc. concd. HCl and the whole was heated for 5 to 6 hrs. on a water bath. After dilu. and filtration, the cooled filtrate was freed from p-$NO_2C_6H_4NH_2$ by neutralization with NaOH and filtration. The filtrate was super satd. with NaOH with pptn. of I, m. 141°. I was reduced by $SnCl_2$ and HCl to *6-amino-4-phenyl-2-methylquinoline*, m. 188°, and condensed with p-$Me_2NC_6H_4CHO$ to *6-nitro-4-phenyl-2-p-dimethylaminostyrylquinoline*, m. 64°. II, similarly prepd from o-$NO_2C_6H_4NH_2$, m. 94°, was reduced to *8-amino-4-phenyl-2-methylquinoline* and condensed with p-$Me_2NC_6H_4CHO$ to give *8-nitro-4-phenyl-2-p-dimethylaminostyrylquinoline*, m. 129°. C. R. ADDINALL



Quinoline derivatives. VII. HANNS JOHN. *Ber.* **63B**, 2657–61(1930); cf. *C. A.* **21**, 914; **25**, 953.—The need for prepg. large amounts of quinuic acid (6-methoxyquinoline-4-carboxylic acid) (I) from quinine or conquinine (II) by oxidation with CrO_3 led to a study of the conditions for obtaining the max. yield in the min. time. The expts., carried out under identical conditions as regards quality of the starting material and reagents and the method of procedure, led to the following results: II by the Skraup method gave 42% I. Addn. of Fe (as $FeSO_4$) raised the yield to 55%. Co, Ni and Vd were without effect. Mn, as MnO_2, $MnSO_4$ or $KMnO_4$, at a concn of 0.1 atom metal per l., gave 75% of very pure I; to obtain this yield, the wt. of CrO_3 used must be at least twice that of the II. The optimum H_2SO_4 concn. is 8%. Replacement of the Mn by Mg, Al, Cu, Ag, Ce and Pb did not raise the yield above 48%, and Hg lowered it to 28%. Cl, As and kieselguhr also did not prove suitable. The procedure for oxidizing 100 g. II in the presence of Mn is given in detail. C. A. R.

1-ω-Halogenoalkylisoquinolines and their derivatives. REGINALD CHILD AND FRANK L. PYMAN. *J. Chem. Soc.* **1931**, 36–49; cf. *C. A.* **24**, 119.—This work was undertaken to prep. substances having amebicidal properties and followed clues indicated by the structure of emetine. The following acyl phenylethylamides were prepd as intermediates from the acid chloride and the amine in Et_2O. *Chloroaceto-β-phenylethylamide* (I), m. 67° (all m. p. cor.); *m-MeO deriv.* (II), m. 56–7°; *β-piperonyl deriv.* (III), m. 72°; *β-veratryl deriv.* (IV), m. 96°; *bromoaceto-β-veratrylethylamide* (V), m. 115°; *cyanoaceto deriv.* (VI), m. 115° but after solidifying m. 127–8°; *hippuro-β-phenylethylamide* (VII), m. 161°; *β-veratryl deriv.* (VIII), crystals with 1 mol. H_2O, m. 85–95°; *β-chloropropiono-β-veratrylethylamide* (IX), m. 102–3°; *γ-bromobutyro deriv.* (X), m. 65°; *chlorovalero deriv.* (XI), m. 60–2°; *Br deriv.* (XII), m. 70–2°. IV (30 g.) in 30 cc. $POCl_3$ and 90 cc. PhMe, heated at 120–30° for 1 hr., give 93.8% of *1-chloromethyl-6,7-dimethoxy-3,4-dihydroisoquinoline-HCl* (XIII), canary-yellow, darkens 210°, effervesces 217°; *picrate*, yellow, m. 196° (decompn.). XIII and KCN in H_2O give *1-chloromethyl-1-cyano-6,7-dimethoxytetrahydroisoquinoline* (XIV), m. 125° (decompn.); if the moist gummy ppt. of XIV is transferred to KCN in H_2O and EtOH and boiled for 0.5 hr., there results 95% of the *1-cyanomethyl deriv.* (XV), corresponding to XIII, m. 173°; the *HCl salt*, pale yellow, m. 205–6° and is readily dissocd. by H_2O; *picrate*, orange-yellow, m. 225° (decompn.); XV also results in 40% yield from VI and $POCl_3$ in PhMe. Reduction of XV with Na and EtOH gives 40% of *1-β-aminoethyl-6,7-dimethoxytetrahydroisoquinoline*, whose *picrate*, yellow, crystg. with 1 mol. EtOH, m. 205°; the *di-HCl salt*, cream colored, m. 276–7° (decompn.). V and P_2O_5, followed by picric acid, give 70% of *1-β-bromomethyl-6,7-dimethoxy-3,4-dihydroisoquinoline*

picrate, orange-yellow, m. 190–1° (decompn.). V and $POCl_3$ give 80% of **XIII**. II and $POCl_3$, followed by picric acid, give *1-chloromethyl-6-m-methoxy-3,4-dihydroisoquinoline picrate*, yellow, m. 169–70° (uncor.); the HCl salt, m. about 170°, appears to contain Me_2CO of crystn. From III there was obtained *1-chloromethyl-6,7-methylenedioxy-3,4-dihydroisoquinoline picrate*, orange-red, m. 179–80° (decompn.); the HCl salt decomps. 204°; it also crystallizes with Me_2CO, m. 150–70°. IX and $POCl_3$ give a mixt. of 2 picrates, m. 235° and 145–85° (both uncor.); the 1st contained no Cl, the 2nd only a trace. Boiling X and $POCl_3$ in PhMe for 30 min. gives a mixt. of 1-γ-chloropropyl-6,7-dimethoxy-3,4-dihydroisoquinoline picrate, which m. 163–4° (not pure), and *4,13-dehydro-9,10-dimethoxy-1,2,3,5,6,13-hexahydrobenzopyrrocolinium picrate*, yellow, m. 201–2°, which is explosive; the *chloride* (**XVI**) crystallizes with $2H_2O$, m. 120–2°, or, anhyd., m. 204–5°; the dry salt is hygroscopic. Reduction of **XVI** with Sn and HCl in EtOH gives 80 5% of *9,10-dimethoxy-1,2,3,5,6,13-hexahydrobenzopyrrocoline*, m. 88–9°; *HBr salt*, m. 186°; *picrate*, yellow, m. 187° (decompn.). **XI** or **XII** with $POCl_3$ give over 90% *1-δ-chlorobutyl-6,7-dimethoxy-3,4-dihydroisoquinoline picrate*, yellow, m. 156–7°; *HCl salt*, m. 172–3° (decompn.); the H_2O soln. has a marked blue fluorescence. With NH_4OH the HCl salt gives 90% of *5,14-dehydro-10,11-dimethoxy-1,2,3,4,6,7-hexahydrobenzopyridocolinium picrate*, golden spangles, m. 185–6°; the *chloride* crystallizes with 1 mol. HCl and 2 mols. H_2O, m. 197–8°; iodide, yellow, m. 210–2°. Reduction gives *10,11-dimethoxy-1,2,3,4,6,7-hexahydrobenzopyridocoline*, m. 59–60°, b_{15} 225°; *HCl salt*, m. 235–7°; *picrate*, bright yellow, m. 172–4°. MeI gives a mixt. of *β-methiodide*, m. 244–5°, and the more sol. *α-methiodide*, m. 228°; heating the latter at 250° gives the *β*-salt. **VIII** and $POCl_3$ give 90% of *9,10-dimethoxy-3-phenyl-5,6-dihydrobenzoglyoxalocoline* (**XVII**), m. 187°; *HCl salt*, m. 286–7° (decompn.), sol. in 25-30 parts cold H_2O; *HBr salt*, m. 293°; *methiodide*, pale cream color, m. 255°; *picrate*, yellow, m. 226–7°; *NO_2 deriv.*, orange-yellow, m. 202°. Heating **XVII** with concd. HCl 5 hrs. at 160° gives the *9,10-di-HO deriv.*, whose *HCl salt* crystallizes with $3H_2O$, m. 293°; $FeCl_3$ gives a deep green color. **XVII** prevented the growth of *Entameba histolytica* in cultures at a dilu. of 1 in 25,000, whereas the control substance, emetine, was effective in a dilu. of 1 to 500,000. All other compds. were far less effective. The salts had no antimalarial activity and were also found to be devoid of trypanocidal activity. The nomenclature used above is based on the following types:

Benzopyrrocoline

Benzopyridocoline

Benzoglyoxalocoline

C. J. West

The γ-triazines. Syntheses of arylaminothioltriazines. A. Ostrogovich and V. Galea. *Atti. accad. Lincei* **11**, 1108–16(1930).—Using the method of prepn. described in a previous paper (*C. A.* **25**, 705), *i. e.*, condensing *cyanoguanidine* with the *arylthiol acid*, 5 new *arylaminothioltriazines* have been prepd.: *phenyl* (I), PhC:N.C(NH_2):N.C(SH):N, m. 281–2° (decompn.); *o-tolyl* (II), m. 243–4° (decompn.); the *m-* (III) and *p- derivs.* (IV), m. 272–3° and 279–80°, resp.; *p-anisyl* (V), m. 282–3° (decompn.). The metallic salts of some of the above, as well as some esters, were prepd. I *picrate*, pptd. from the EtOH soln. by adding picric acid, m. 193–4° (decompn.). I also gives insol. salts with many heavy metals as Ag, Cu, Hg, Pb, Fe, etc. The Ag salt shows very slight discoloration in sunlight. I is also readily methylated by adding the calcd. amt. of Me_2SO_4 and KOH, the product being insol. in alkali, m. 170–1°. II, III, IV and V, form similar salts with the heavy metals as well as picrates. The *picrates* m. 224–5°, 210–1°, 191–2°, 198–9°, resp. A. W. Contieri

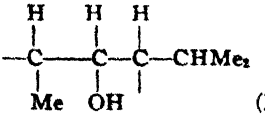
The influence of light, carbon monoxide and quinone on the methylene blue reduction. Hiroshi Tamiya, Tatsutaro Hida and Kiyoshi Tanaka. *Acta Phytochim.* **5**, 119–55(1930).—$AcCO_2H$, "Koji" acid, $AcCH_2CO_2Et$, phloroglucinol and resorcinol reduce methylene blue (I) in the absence of O_2 at a certain p_H. Light energy is essential for this reaction. The presence of a mobile H atom in these substances (keto-enol tautomerism) is emphasized. The enzymatic reduction of I was studied with *Bacterium pasteurianum* and liver exts. It also was found to be speeded up by light. The I mol. is activated in this photochem. reaction, not the H donor or the dehydrase.

The I reduction by chem. means or by liver exts. is not influenced by CO (II). However, I reduction by bacterial suspensions was found more or less prevented by II. The ratio I:II dets. the degree of inhibition. The light does not influence it. II apparently prevents the adsorption of I on the bacterial surface. AcOH dehydrase is not affected by II. Small amounts of quinone interfere with the chem. as well as the enzymatic reduction of I. Extensive exptl. data are given and a special app. is described.

E. GEBAUER-FUELNEGG

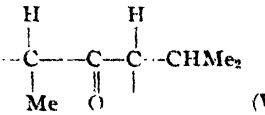
Thiodiazines. VI. PRAFULLA KUMAR BOSE AND BIRENDRA KUMAR NANDI. *J. Indian Chem. Soc.* **7**, 733–9(1930); cf. *C. A.* **19**, 831.—The mechanism proposed by Guha and Roy-Choudhury (*C. A.* **23**, 139), for the formation of the thiodiazine PhNH-NHC:N.N:CPh.CH_2.S from the action of $PhNHNHCSNHNH_2$ on $BrCH_2COPh$ is different from that suggested by B. who pointed out that varying quantities of thiazoles are formed in the above condensation (*C. A.* **20**, 415). The formation of such thiazoles can be explained by the assumption of an intermediate of the type $NH_2N:C(NHR)SCH_2COPh$. Reactions between thiosemicarbazides and *p*-$MeC_6H_4COCH_2Br$ led, however, either to the formation of a thiodiazine or to a thiazole, but not to both as expected. 4-Substituted thiosemicarbazides gave thiodiazines whereas thiosemicarbazide gave a thiazole. One g. $NH_2NHCSNH_2$ and 2.3 g. *p*-$MeC_6H_4COCH_2Br$ (I) were shaken with 35 cc. abs. alc., and after refluxing for 20 min. the mixt. was cooled and dild. with Et_2O. The crude product was collected, washed with Et_2O, dried and dissolved in dil. HCl. After filtering and neutralizing with Na_2CO_3, the free base *2-keto-4-p-tolyl-2,3-dihydro-1,3-thiazole hydrazone* (II) was pptd., which after recrystn from MeOH, m. 178°; *HCl salt*, m. 133°; *benzylidene deriv.*, m. 205° (identical with the condensation product of PhCH:NNHCSNH$_2$ and I); *isopropylidene deriv.* m. 230°, *Bz deriv.*, m. 201°; *Ac deriv.*, m. 195° (identical with the condensation product of AcNH-NHCSNH$_2$ and I). The formation of the PhCH and Ac derivs. rules out the formulation of II as a thiazole NH:C.S.CH:C(C_7H_7).NNH_2. II reacted with isothiocyanates, forming addn. compds. of the type, NH.C(C_7H_7):CH.S.C:NNHCSNHR (R = Me, Ph, *o*- and *p*-tolyl, m. 146°, 191°, 174° and 166°, resp.), and with HCNS to form HN.C(C_7H_7):CH.S.C:NNHCSNH$_2$ (III), m. 218. III dissolved in abs. alc., condensed with II to give [HN.C(C_7H_7):CH.S.C:N]$_2$, m. 120°. $NH_2NHCSNHMe$ condensed with II to give *2-methylamino-5-p-tolyl-1,3,4-thiodiazine*, MeNH-C:N.NH.C(C_7H_7):CH.S, m. 249° (*HCl salt*, m. 195°); *2-isobutylamino homolog*, m. 159°, was prepd. from II and *iso*-BuNHCSNHNH$_2$ (*HCl salt*, m. 125°; *Ac deriv.*, m. 167°); *2-phenylamino analog*, m. 198° (*HCl salt*, m. 135°; *Ac deriv.*, m. 170°); *2-o-tolylamino compd.*, m. 179° (*HCl salt*, m. 171°; *Ac deriv.*, m. 190°); and *2-p-tolylamino isomer*, m. 187° (*HCl salt*, m. 199°; *Ac deriv.*, m. 154°).

C. R. ADDINALL



Correction to G. Hahn and W. Schuch: Yohimbehe alkaloids. VI. Two further **secondary alkaloids of yohimbine.** R. LILLIG. *Ber.* **63B**, 2680(1930).—H. and S state (*C. A.* **24**, 5039) that L.'s α-yohimbine does not lose in wt. when dried at 105° and that the 15% loss cannot be ascribed to a const. hydrate or alcoholate. This is due to the use of aq. MeOH instead of EtOH for the recrystn.; from 95% alc. the compd seps. with 1 mol. each of EtOH and H_2O; the loss in wt., compn. and titration results agree with the formula $C_{20}H_{26}O_3N_2$.EtOH.H_2O. The alc. can be detected by rubbing 2 g. of the base with 5 cc. H_2O, distg. off 2 cc. and testing the distillate with I-KI-NaOH or with BzCl-NaOH.

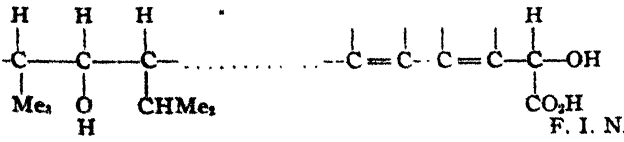
C. A. K



Sulfonation of alkaloids. ZENJIRO KITASATO AND KAKUJI GOTO. *Ber.* 63B, 2696–700(1930).—In general, practically nothing is known as to the reactions which take place between alkaloids and concd. H_2SO_4. K. and G have found that alkaloids having a HO (or MeO) group on the aromatic nucleus, with a free *p*-position, are sulfonated by concd. (not fuming) H_2SO_4 below 10°; the resulting acids generally form well-defined crystals and the SO_3H group always combines with the basic N to an inner salt. In this way were obtained *papaverine-* (I), *apomorphine-* (II) and *sinomeninesulfonic acid* (III). These acids no longer give the diazo reaction and the SO_3H group is probably in the *p*-position to the phenolic HO group. Strychnine, which has no HO (or MeO) group, and brucine, in which the *p*-position to the HO group is not free, are not sulfonated under these conditions, and neither are those derivs. of sinomenine and thebainone, such as bromosinomenine, disinomenine and dithebainone (IV), in which

judging from the failure to give the diazo reaction, the *p*-position to the HO group is not free. For I, the 2-position for the SO_3H group is assumed from analogy with nitropapaverine. To det. whether the color reaction of certain alkaloids with H_2SO_4 is due to the formation of a colored compd. or to a decompn., IV was studied first. It dissolves in concd. H_2SO_4 with deep red color, and when poured on ice forms a colorless soln. which with Na_2CO_3 regenerates the unchanged IV. I m. 301° (decompn.), easily sol. in Na_2CO_3, alkalies and $Ba(OH)_2$. II, needles with $3H_2O$, m. above 300°. III, m. 265–7°. *Sinomeninonesulfonic acid*, from sinomenine hydrate, prisms with 0.5 H_2O, m. 275–80°, gives in MeOH with $NH_2OH.HCl$ a *dioxime*, m. above 300°, also obtained by sulfonation of sinomenine hydrate dioxime. C. A. R.

Saponin of Panax repens, Maxim. IV. Panaxsapogenin. S. Aoyama. *J. Pharm. Soc. Japan* **50**, 1076–95(1930); German abstr. 139–44; cf. *C. A.* **24**, 125.—A. previously has reported on *panaxsapogenin* (I) and *panaxprosapogenin* (II) and shown that II is made up of *panaxsapogenin* ($C_{36}H_{58}O_4$) and gluconic acid. Recently Kotake, Matsubara and Kimoto (*J. Chem. Soc. Japan* **51**, 396–400(1930)) have shown that saponin obtained from *Panax repens, Maxim* is identical to that obtained from *Aralia chinensis, L. var grabrescens*. K. also proposed to change the mol. formula of $C_{36}H_{58}O_4$ (Murayama and Tanaka, *C. A.* **21**, 3359) to $C_{30(39)}H_{52(49)}O_3$, but he could not account for the large mol. wt. of its Ac deriv. A. obtained slightly different results. Analysis of I indicates the mol. formula $C_{36}H_{58}O_4$ as previously reported. *Dihydrosapogenin*, $C_{36}H_{60}O_4H_2O$, m. 290–3°. I probably contains 2 double linkages, but no MeO, hydroxymethylene, ketone or aldehyde groups. I forms a *diphenylurethan*, $C_{50}H_{68}O_6N_2$, decomps. 133–40°, hence contains 2OH groups. *Me ester* of I, $C_{37}H_{60}O_4$, m. 196°, contains 2 alc. OH and 1MeO groups. *Monoacetylsapogenin* (III), $C_{38}H_{60}O_5$, m. 262–4.5°, and corresponds to the $C_{32}H_{54}O_4$ of K. Only 1OH group is acetylated, the other is probably tertiary alc. *Diacetylsapogenin anhydride* (IV), m. 315–8°. IV, when treated with KOH followed by HCl, gave III. *Me ester* of III, $C_{39}H_{62}O_5$ (V), m. 221°. Oxidation of V with CrO_3 gave a diketone, $C_{37}H_{56}O_4$ (VI), m. 182–3°, and an acid decompg. 245–8°. This acid is under further investigation. VI shows neither the Liebermann nor the CHI_3 reaction, hence it contains no —COMe group. VI is an unsatd. ketone. Reduction of VI by Clemmensen's method gave the original compd. *Dioxime* of VI, $C_{37}H_{58}O_4N_2$, decomps. 237°, probably contains a —C CO C:C.C:C— linkage. VI forms a *monosemicarbazone*, $C_{38}H_{59}O_4N_3$, which does not m. 290°. V gives neither the osazone, pyrrolen or pyrazoline reactions, hence the position of the C:O group must be either at 1 and 5 or further apart. A. suggests the following structure to explain the position of OH and CO groups in I and VI:



(I)

(VI)

Sapon. of V gave the Me ester, m. 195°, while I gave a compd., $C_{36}H_{56}O_4$ (VII), m. 293°, which did not depress the m. p. of I. VII is probably an isomer of I and is called *α-isopanaxsapogenin*. III and VI also give VII. The exact mechanism of the formation of the isomer is not known. I is stable toward concd. HCl, even on boiling, and also alc. HCl. When treated with dry HCl in excess MeOH I gives a compd. m. 268° (VIII). VIII is probably another isomer of I and is called *β-isopanaxsapogenin*. A. suggests the following partial structure for I:

F. I. Nakamura

Digitalis glucosides. III. Glucosides of Digitalis lanata. Sydney Smith. *J. Chem. Soc.* **1931**, 23–5; cf. *C. A.* **24**, 2753; **25**, 708.—In addn. to digoxin, which was previously reported, gitoxin, m. 285° (cor., decompn.), $[\alpha]^{20}_{5461}$ 3.5° (C_5H_5N, *c* 1.02), has been isolated from the leaves of *Digitalis lanata;* this has hitherto been found only in the leaves of *D. purpurea*. Other glucosides in the leaves are being examd. C. J. West

Brazilin and hematoxylin questions. XI. Hydroxybenzylchromanones. Paul Pfeiffer, Erwin Breith and Hans Hoyer. *J. prakt. Chem.* **129**, 31–54(1931); cf

C. A. **24**, 4301.—Chromanone (I) (0.5 g.) and 0.46 g. *p*-$MeOC_6H_4CHO$ in abs. EtOH with dry HCl at 0° give 0.51 g. *4'-methoxybenzalchromanone*, yellow, m. 134°; 0.0001 mol. in 1 cc. concd. H_2SO_4 gives a blood-red color. I and 0.55 g. vanillin Me ether give 0.28 g. *3',4'-di-MeO deriv.*, pale yellow, m. 117°; color in H_2SO_4 blood-red. I and 0.5 g. piperonal give 0.45 g. *3',4'-methylenedioxy deriv.*, yellow, m. 134.5–7°; color, Bordeaux red. I and 0.5 g. vanillin give 0.62 g. *3'-methoxy-4'-hydroxy deriv.*, yellow, m. 126–9°; color, deep blood-red; *Ac deriv.*, golden yellow, m. 160° (84% yield). I and 0.47 g. 3,4-$(HO)_2C_6H_3CHO$ give 0.42 g. of *3',4'-di-HO deriv.*, golden yellow, m. 224–5°; color, wine-red; *di-Ac deriv.*, m. 166° (52% yield). 7-Methoxychromanone (5 g.) and 4.3 g. isovanillin in abs. EtOH with HCl give 9.2 g. *4',7-dimethoxy 3'-hydroxybenzalchromanone*, bright yellow, m. 153-4°; color, deep orange; *Ac deriv.*, pale yellow, m. 139–40°; catalytic reduction of the Ac deriv. gives the *benzyl deriv.*, red, m. 123–4°; *oxime*, m. 160–1°; *Ac deriv.*, m. 90–1°. 7-Hydroxychromanone and vanillin Me ether give *3',4'-dimethoxy-7-hydroxybenzalchromanone*, brown, m. 245 9°; color, dark red; *Ac deriv.*, yellow, m. 151–2°. *3',4'-Methylenedioxy deriv.*, brown, m. 234 6°; color, blood-red; *Ac deriv.*, yellow, m. 132.5–4°. *3'-Methoxy-4',7-dihydroxy deriv.*, golden yellow, m. 230–1.5°; color, dark red; *Ac deriv.*, m. 151–2.5°. *3',4',7-Trihydroxy deriv.*, yellow, m. 250–3°; color, blood-red; *tri-Ac deriv.*, pale yellow, m. 132–4°. The corresponding *benzyl deriv.*, yellow, m. 201–2°; color, light wine-yellow; *Ac deriv.*, m. 117°. 7,8-Dimethoxychromanone with $AlCl_3$ or concd. HBr give the *7,8-di-HO deriv.*, crystg. with 1 mol. H_2O, m. 188–8.5°; color, citron-yellow; *di-Ac deriv.*, m. 111°; *semicarbazone*, pale brown, m. 224–5° (decompn.). With *p*-$MeOC_6H_4CHO$ and HCl in EtOH there results *4'-methoxy-7,8-dihydroxybenzalchromanone*, greenish yellow, m. 192°; color, deep brownish red; *Ac deriv.*, light yellow, m. 140°. *3',4'-Di-MeO deriv.*, crystg. with 1 mol. H_2O, light yellow, m. 174 5°; color, carmine red; *Ac deriv.*, pure yellow, m. 183°; the corresponding *benzyl deriv.*, reddish needles, m. 177°; *Bz deriv*, m. 177.5 8°. *3'-Methoxy-4',7,8-trihydroxybenzalchromanone*, crystg. with 1 mol. H_2O, yellow, m 206–7°; attempts to remove the H_2O by heating at 17 mm. over PhMe caused decompn.; *Ac deriv.*, m. 180 1°. *3',4',7,8-Tetra-HO deriv*, light yellow, begins to decomp. at 220° and is complete at 265°; color, brick-red; *Ac deriv.*, m. 166 7°; the corresponding *benzyl deriv.*, yellow-red, decomps. above 200°; *Ac deriv*, m. 107–8°. C. J. West

Santonin. Karl Josephson. *Svensk Farm. Tids.* **35**, 29 33(1931).—The lactone ring of santonin is opened by NH_3 in alc. giving santoninic acid amide. This reaction is easily reversed. J. gives a general discussion on the constitution of santonin with bibliography up to Clemo and Haworth (*C. A.* **24**, 4046). A. R. Rose

Hydrolysis of benzoylated amino acids and polypeptides. Stefan Goldschmidt and Wilhelm Füner. *Ann.* **483**, 190-216(1930).—The hydrolysis of various benzoylated mono- and diamino acids, aminohydroxy acids and polypeptides with NaOH (2% usually) at 25° and 100° and H_2SO_4 at 100° is reported. The rate of alk. hydrolysis of the monoamino acids increases with rise in temp. and HO-ion concn.; for a definite HO-ion concn., the coeff. decreases with increasing length of the C chain. Alk. hydrolysis of hippuric acid is increased at both 25° and 100° by the addn. of NaCl but is decreased by added glycine. The *O*-Bz group is eliminated from *O,N* dibenzoyl serine and -tyrosine at 25°; at 100° both Bz groups are readily eliminated from the former compd. Alk. hydrolysis of dibenzoylarginine causes the very ready elimination of 1Bz group with the production of α-benzoylornithine; the velocity of hydrolysis of the second Bz group is measurable when 8% NaOH is used. Similarly, α,ε dibenzoyllysine (I) is first hydrolyzed to the α-Bz deriv. With benzoylated glycyl-, diglycyl- and alanylglycylglycines, the peptide linkings are rapidly broken; during this hydrolysis little BzOH is produced. The rate of hydrolysis of benzoylated mono amino acids by 70% H_2SO_4 at 100° increases with the length of the C chain. Dibenzoyl arginine behaves similarly with acidic hydrolytic agents as with alk., but the behavior of I is reversed, the α-Bz group being eliminated first. The peptide linkings are first broken when the above benzoylated peptides are hydrolyzed with 70% H_2SO_4. The velocity of hydrolysis of benzoylproteins is greater with 30% than with more concd H_2SO_4; the rate corresponds with the sp. cond. of the acid. The velocity of hydrolysis of hippuric acid by 70% H_2SO_4 is increased by the addn. of glycine. C. J. West

A higher alcohol obtained from "Cortinellus Shiitake." Midzuho Sumi. *Bull. Inst. Phys. Chem. Research* (Tokyo) **9**, 966-9(1930), *Abstracts* 92 (in English) published with *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **15**, Nos. 278-81.—*A higher satd. alc.* $C_{28}H_{48}O$ is obtained from finely powd. *Cortinellus Shiitake*, needles or prisms, sol. in Et_2O, C_6H_6, $CHCl_3$, not easily sol. in EtOH, Me_2CO, etc., m. 245–55°, $[\alpha]_D^{23}$

—22°. *Acetate*, m. 260–5°, $[\alpha]_D^{23}$ —30.2°. *Benzoate*, m. 210°. *Palmitate*, m. 171–2°. The spectrum shows no special absorption band. K. KONDA

The bile acids. XXXI. The constitution of pseudocholoidanic acid. HEINRICH WIELAND, LUDWIG ERTEL AND ELIZABETH DANE. *Z. physiol. Chem.* **194**, 107–18 (1931).—The study of pseudocholoidanic acid has been resumed with the hope of detg. the location of 2 remaining C atoms in the bile acids. The tetrabasic pseudocholoidanic acid $C_{24}H_{34}O_{10}$ is formed along with the pentabasic choloidanic acid, $C_{24}H_{36}O_{10}$, when desoxybilianic acid is oxidized by HNO_3. The former view that this oxidation breaks open ring III is now abandoned in view of the subsequent location of a Me group at C_{11}. Pseudocholoidanic acid forms a neutral tetra-Me ester, but no keto groups can be demonstrated, hence the remaining 2O atoms must be present in ether or lactone linkage. When heated it loses CO_2 and $2H_2O$ and forms a pyropseudocholoidanic acid, $C_{23}H_{30}O_6$, which is monobasic and yields a mono-Me ester, m. 192°. Treatment of the pyro acid with alc. KOH opens up a lactone ring with formation of a dibasic acid, $C_{23}H_{32}O_7$, m. 212°, from which a di-Me ester was obtained with CH_2N_2. The mono-Me ester of pyropseudocholoidanic acid was also obtained by heating the di-Me ester of pseudocholoidanic acid. A by-product in the prepn. of the pyro acid was a dibasic acid, $C_{22}H_{32}O_5$. The open pyro acid is tribasic when titrated hot, due to hydrolysis of an anhydride grouping. Desoxybilianic acid in AcOH takes up 2Br, yielding 50–60% of *dibromodesoxybilianic acid*, m. 215° (decompn.). Treatment of this with *N* KOH in MeOH removes 1HBr with formation of *bromodesoxybilienic acid*, m. 218° (decompn.), in 80% yield; *tri-Me ester*, m. 93°. Both of these brominated acids revert to desoxybilianic acid when reduced with Zn and HCl. Oxidation of the unsatd. bromo acid with HNO_3 yields pseudocholoidanic acid. This new manner of obtaining pseudocholoidanic acid proves it to be a lactonetetracarboxylic acid, in which ring II has been opened by breaking the linkage between C_6 and C_7, since the oxidation product contains no Br. Formulas representing the characteristic groupings of pseudocholoidanic acid and its pyro acid are proposed. **XXXII. Attempts at a new breakdown of desoxybilianic acid.** ELIZABETH DANE AND HEINRICH WIELAND. *Ibid* 119–23.—In dibromodesoxybilianic acid (vide supra) both Br atoms are on C_6. One is easily removed as HBr, but the 2nd is tenaciously held as would be expected from the presence of an adjacent double linkage. Oxidation of the unsatd. bromodesoxybilienic acid by alk. $KMnO_4$ converts it into the tribasic *5-hydroxy-6-ketodesoxybilianic acid*, $C_{24}H_{34}O_9$, m. 233–5°; *oxime*, m. 200°. Esterification with CH_2N_2 yields a *tri-Me ester*, m. 154°, while esterification with MeOH-HCl yields an *isomeric tri-Me ester*, m. 178°. The difference between these isomers is not understood. The HO acid when boiled with AcOH and HCl loses H_2O and forms a *diketolactonedicarboxylic acid*, $C_{24}H_{32}O_8$, m. 258–60°. Catalytic hydrogenation of the latter yields 70% of a *6-ketodesoxybilianic acid*, $C_{24}H_{34}O_8$, m. 255°; *tri-Me ester*, m. 108°. Oxidation of the above HO acid with fuming HNO_3 gave a *pentabasic acid*, $C_{24}H_{36}O_{11}$, m. 180°. A. W. DOX

Tauroisolithocholic acid from chicken bile. TADAO HOSIZIMA, HIROSI TAKATA, ZIRO URAKI AND SIGETOSI SIBUYA. *J. Biochem.* (Japan) **12**, 393–7(1930).—Chicken bile is freed from mucus by alc. and is concd. on the water bath to the original vol. of 1 l. $FeCl_3$ is then added until the acid soln. gives no further ppt. The ppt. is filtered off and is decompd. with warm Na_2CO_3. The filtrate is evapd. and the dry residue extd. with alc. The alc. soln. is decolorized with animal charcoal and evapd., the residue again taken up in alc. and decompd. with H_2SO_4 and mixed with ether. The flocculent ppt. is now filtered off. This ppt. is dissolved in dil. Na_2CO_3, gradually acidified with HCl and extd. by shaking with ether. The ppt. thus formed is recrystd. several times from dil. alc. and gives a yield of 2.13 g. These crystals are not sol. in H_2O, ether, petroleum ether or benzene, but do dissolve easily in alc., AcOH or Me_2CO; they give the Pettenkofer reaction and m. 210–1°. In abs. alc. soln. (0.54%) they have a sp. rotation of 65.74°. Its elementary compn. corresponds to the formula $C_{23}H_{39}OCONHCH_2CH_2SO_3H$. Heated for 24 hrs. under a reflux with 5% NaOH, it gives a mass of beautiful roset-shaped needles. The Na salt was converted to a Ba salt which was recrystd. from dil. alc. by a special procedure. Analyses on this Ba salt show that the bile acid is related to lithocholic acid, and is identified as tauroisolithocholic acid. S. MORGULIS

ELLIS, CARLETON: **Hydrogenation of Organic Substances.** 3rd ed. New York: D. Van Nostrand Co., Inc. 986 pp. M. 15. Reviewed in *Ind. Eng. Chem.* **23**, 342 (1931).

Hydrocarbons. ALFONS DESCHAUER. Ger. 515,177, Dec. 1, 1926. Partly hydrogenated polycyclic hydrocarbons are prepd. by treating the acid sulfates of cyclic hydrogenated alcs. with aromatic hydrocarbons in the presence of H_2SO_4. Thus, cyclohexanyl sulfuric acid and C_6H_6 yield phenylcyclohexane. The acid sulfates used as initial materials need not be separately prepd. Thus, an aromatic hydrocarbon may react, in the presence of H_2SO_4, with a cyclic unsatd. hydrocarbon such as cyclohexene, or with a cyclic hydrogenated alc. Examples are given.

Hydrocarbons. I. G. FARBENIND. A.-G. Fr. 693,054, Mar. 31, 1930. Hydrocarbons of high b. p. are converted into hydrocarbons of lower b. p. by cracking or hydrogenation in the presence of catalysts composed of metal compds. of the type of acetylacetonates, with or without other catalysts.

Partial combustion of hydrocarbons. JOHANN S. OHLENDIECK-DOLGE. Ger. 514,394, May 4, 1928. This relates to the manuf. of mixts. contg. CO and H by treating hydrocarbons with air or other oxidizing gas at a raised temp. in the presence or absence of catalysts. The improvement consists in using an alloy of Fe, Cr, and Ni, that has been fused *in vacuo*, for constructing the parts of the reaction chamber that come into contact with the gases.

Condensing diolefins with other hydrocarbons. I. G. FARBENIND. A.-G. Brit. 335,512, July 5, 1929. In the further application of the general type of reactions described in Brit. 315,312 (*C. A.* **24**, 1649), isoprene, toluene and Na are heated in an autoclave at 160° (yielding 3-methyl-5-phenyl-2-pentene or 2-methyl-5-phenyl-2-pentene. β,γ-Dimethylbutadiene, toluene and Na yield 2,3-dimethyl-5-phenyl-2-pentene, and butadiene, tetrahydronaphthalene and Na yield butenyltetrahydronaphthalene. Cf. *C. A.* **24**, 3247.

Aliphatic compounds. HENRY DREYFUS. Fr. 692,736, Mar. 25, 1930. Org. O compds. are synthesized by passing the reaction gases through a no. of reaction vessels in series in an open circuit. An example is given of the prepn. of MeOH from water gas. Cf. *C. A.* **25**, 963.

Organometallic compounds. LOUIS P. V. LECOQ. Fr. 692,949, July 1, 1929. Salts and complex metallic compds. of dithiocamphocarboxylic acid which are sol. in org. solvents, particularly in animal and vegetable oils, are prepd. by double decompn. or by the action of the acid on oxides. Examples are given of the prepn. of the Cu, Au, Ag and Hg salts and of a complex compd. contg. As which is sol. in olive oil, by the reaction of dithiocamphocarboxylic acid with *p*-hydroxy-*m*-aminophenylarsonic acid. Cf. *C. A.* **24**, 2138.

Diazo compounds. I. G. FARBENIND. A.-G. (Erich Lehmann, inventor). Ger. 515,205, Nov. 6, 1928. Diazo compds. of unsulfonated diphenylamine derivs. are salted out from their solns. at atm. temp. by means of neutral, unhydrolyzed salts in the presence of a weak acid, *e. g.*, H_3BO_3, and a compd. capable of reacting with HNO_2, *e. g.*, urea. The oxidation products which sep. after the diazotization should be removed before salting out. The products are stable in the cold and in warm, damp air. Examples are given.

Alcohols from olefins. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 335,551, May 23, 1929. Olefins (including those contg. 2 or more double bonds) are hydrated in the vapor phase in the presence of a metal of the Pt group, Au, Ag, Cu, Fe, Ni, Co, Cr, Ta, V, W, Mo or Mn or their salts or other compds. (most suitably compds. which during the reaction yield the metals such as oxalates, carbonyls and the like, although compds. such as Bi vanadate, Cu vanadate or Cu phosphate also may be used). Several examples with details of procedure are given for treating ethylene and propylene.

Cyclic aldehydes. I. G. FARBENIND. A.-G. (Georg Kalischer, Heinz Scheyer and Karl Keller, inventors). Ger. 514,415, Feb. 3, 1927. The aldehyde group is introduced into oxygenated cyclic compds. by treating these with formyl derivs. of secondary amines and a chloride or oxychloride of P or S. The reaction may be effected in an inert solvent. Thus, β-naphthol may be added to a benzene soln. of the product obtained by treating formylmethylaniline with $POCl_3$, while cooling; 2-naphthol-1-

aldehyde is obtained from the mixt. after standing for about 20 hrs. Other examples are given also. The method may be used to prep. aldehyde derivs. of anthrone, benzanthrone, naphthostyril, hydroxythionaphthene and like compds. Cf. *C. A.* **24**, 3800.

Polycyclic ketones. I. G. FARBENIND. A.-G. (Otto Nicodemus and Walter Berndt, inventors). Ger. 514,416, Dec. 16, 1925. Polycyclic ketones are prepd. from aromatic or heterocyclic ketones having halogen in the *o*- or *peri*-position to the CO group, by treating these at a raised temp. with alkali or alk. earth salts or with feebly alk. acid-binding agents. The ketones may be treated in the gas or liquid phase and in the presence or absence of catalysts, *e. g.*, Cu or $CuCO_3$. Thus, fluorenone may be prepd. by heating *o*-chlorobenzoylbenzene with Na_2CO_3 at 300° for some hrs. Other examples are given also. Cf. *C. A.* **25**, 1260.

Acetals. CONSORTIUM FÜR ELEKTROCHEM. IND. G. M. B. H. (Hans Deutsch and Willy O. Herrmann, inventors). Ger. 513,796, Jan. 26, 1926. Addn. to 502,431. The method of Ger. 502,431 (*C. A.* **24**, 4793) is modified by using alcs. contg. water. The water is converted into AcH, which may be fractionated out of the reaction products or removed by washing, *e. g.*, with the alc. used. The yield of acetals may be increased by partly condensing the reaction products and returning the condensate to the reaction vessel, or by circulating the products through the vessel. Examples are given.

Aldehyde bases. PRODUITS ROCHE, SOC. ANON. Belg. 370,846, July 31, 1930. Hydroaromatic aldehydes are condensed with CH_2O and aliphatic amines.

Aldehyde amines. THE NAUGATUCK CHEMICAL CO. Fr. 692,835, Mar. 27, 1930. The deterioration of condensation products of aldehydes with amines such as heptylic aldehyde with $PhNH_2$ is retarded by treating the products with a polyhydroxylated or polyhydroxy substituted aromatic compd. such as catechol, resorcinol, pyrogallol, dinitrosoresorcinol, hydroquinone or its mono- or di-chloro deriv.

Esters. OTTO FUCHS (to Deutsche Gold und Silber-Scheideanstalt vorm. Roessler). U. S. 1,791,238, Feb. 3. In producing esters such as MeOAc, aliphatic acids such as HOAc and alcs. such as MeOH are caused to react together at temps. of about 100–180°, corresponding to working pressures of 2–10 atm., in the presence of catalysts such as H_2SO_4 or $NaHSO_4$ which are capable of producing moderate H-ion concns., and the ester formed is continuously removed from the reaction mixt. as produced.

Vinyl esters. WILLY O. HERRMANN, HANS DEUTSCH and ERICH BAUM (to Consortium für Elektrochemische Industrie). U. S. 1,790,920, Feb. 3. An excess of C_2H_2 is passed through a monocarboxylic aliphatic acid such as HOAc in the presence of not more than about 4.3% of a Hg compd. such as Hg acetate and the resulting vinyl ester is removed from the reaction mixt. by entrainment with the escaping excess of C_2H_2 and is recovered by rectification. Several examples with details of procedure are given. Cf. *C. A.* **24**, 627.

Conversion products of vinyl esters. CONSORTIUM FÜR ELEKTROCHEM. IND. G. M. B. H. (Hans Deutsch and Willy O. Herrmann, inventors). Ger. 515,307, Mar. 11, 1927. Ketene and other ketones, AcH, acid anhydrides and vinyl ethers are among the products obtained by passing vaporized vinyl esters at a temp. between 250° and 500° and at atm. or raised pressure through a packed reaction vessel which may contain a catalyst. Thus, the reaction vessel may be packed with wood charcoal on which ZnO has been deposited. Examples are given.

Polyvinyl alcohol esters. I. G. FARBENIND. A.-G. Fr. 692,816, Mar. 27, 1930. Sol. mixed esters of polyvinyl alc. are made by the reaction simultaneously or successively of the alc. mixts. with acid halides or condensation products obtained by elimination of halogen hydride from halide acids. The products are converted to an insol. form by heat. Thus, a mixt. of polyvinyl alc., EtCl, naphthenic acid chloride, PhCl and pyridic bases are heated to 35–40° for 24 hrs. The product is sepd. by MeOH and filtering. It can be formed into a film from its soln. in acetone. Other examples are given.

Alkyl chlorides. E. I. DU PONT DE NEMOURS & CO. Fr. 692,790, Mar. 26, 1930. Alkyl chlorides are made by bringing a mixt. of vapors contg. alc. and HCl into contact with an aq. soln. of a metallic chloride such as $ZnCl_2$ or $FeCl_3$ at a temp. of about 100–160°. The mixt. of vapors may be formed by the reaction of NaCl, H_2SO_4 and alc. at a high temp. An example is given of the prepn. of EtCl. Cf. *C. A.* **25**, 303.

Calcium benzoate. TH. GOLDSCHMIDT A.-G. Fr. 692,521, Mar. 21, 1930. Phthalic anhydride is ground with an aq. suspension of $Ca(OH)_2$ and heated to a temp. above 350°. The mixt. is introduced gradually into the reaction chamber and a dilg. agent such as some of the material already transformed may be added to the mixt.

Sulfonates of pyridine and its homologs. I. G. FARBENIND. A.-G. Brit. 335,817, Nov. 26, 1928. In the sulfonation of pyridine and its homologs (suitably with fuming

H_2SO_4), Hg or a Hg salt such as the sulfate is used as catalyst. Examples are given of the sulfonation of pyridine and of α-picoline. Previous use of various other catalysts also is mentioned.

Stabilizing solutions of salts of aromatic stibinic acids. I. G. FARBENIND. A.-G. (Hans Schmidt, inventor). Ger. 515,113, Feb. 25, 1927. A polyhydric alc., *e. g.*, glycerol or glucose, is included in the solns. The alc. and the salt may be present in equal amounts.

Amine derivatives. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,180, April 2, 1930. *N,N'*-Thio derivs. of primary and secondary amines are made by the interaction of a primary or secondary amine with a chloride of S in aq., neutral or alk. suspension. Examples are given of the prepn. of $Et_2NSSNEt_2$ from Et_2NH and $(CH_2)_5NSSN(CH_2)_5$ from piperidine.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. (Max Kugel, inventor). Ger. 513,025, June 12, 1927. Mixts. of α- and β-aroylaminoanthraquinones or their halogen derivs. are sepd. by treatment in alc. suspension with caustic alkali at a temp. sufficiently low to avoid sapon. The α-derivs. remain undissolved, while the β-derivs. go into soln., and can be recovered by acidification. Examples are given. Cf. *C. A.* **25**, 965.

Benzanthrone derivatives. I. G. FARBENIND. A.-G. (Heinrich Neresheimer and Willy Eichholz, inventors). Ger. 515,327, Aug. 11, 1926. Addn. to 431,774. According to Ger. 431,774, *Bz*-1,*Bz*-1'-Dibenzanthronyls are prepd. by treating benzanthrone, or its derivs. having the 2-position free, with acid oxidizing agents. It is now found that the reaction proceeds differently if oxidation is effected with MnO_2 and moderately dil. H_2SO_4, products sol. in alkalies and in cold bisulfite soln. being obtained. Like products can be prepd. from benzanthrone derivs. substituted in the 2-position, and in treating these, other acid oxidizing agents may be used. Examples are given. Cf. *C. A.* **25**, 1262.

Naphthocarbazole derivatives. I. G. FARBENIND. A.-G. (Albert Schmelzer, Fritz Ballauf and Heinrich Hefner, inventors). Ger. 514,420, Feb. 9, 1929. See Fr. 689,515 (*C. A.* **25**, 966).

Alkyl cyclohexanols and cyclohexanones. SCHERING-KAHLBAUM A.-G. (Walter Schoeller and Hans Jordan, inventors). Ger. 515,112, Jan 27, 1928. Addn. to 512,881. The hydrogenation process described in Ger. 512,881 (*C. A.* **25**, 1259) is carried out in the presence of a surface catalyst, *e. g.*, Al-Mg hydrosilicate. The hydrogenation catalyst (Ni) may be deposited on the surface catalyst. Examples are given. Cf Ger. 512,236 (*C. A.* **25**, 974).

Phenols. I. G. FARBENIND. A.-G. (Friedrich W. Stauf and Gerhard Kröner, inventors). Ger. 513,798, Mar. 20, 1928. See Brit. 308,220 (*C. A.* **24**, 130).

Improving the odor of phenols. GEWERKSCHAFT MATHIAS STINNES. Ger. 515,467, Oct. 29, 1927. Addn. to 514,341. The method of Ger. 514,341 (*C. A.* **25**, 1336) is modified by partially etherifying the phenols instead of partially esterifying.

Indoles. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 692,590, Mar. 24, 1930. See Brit. 330,332 (*C. A.* **24**, 5770).

Styrenes. THE NAUGATUCK CHEMICAL CO. Fr. 693,876, April 14, 1930. Styrenes are prepd. by heating an alkylbenzene and C_6H_6. A substance such as S or a mixt. of $C_2H_4Cl_2$ and S capable of forming a stable compd. with the H liberated may be added.

Acetic acid. HENRY DREYFUS. Fr. 692,735, Mar. 25, 1930. The vapor of CH_2O alone or mixed with CO is submitted to the action of heat under a pressure of 100–300 kg. or more. A temp. of 300–400° is preferred and the CH_2O may be used in the form of formal and in the presence of steam. Catalysts such as inorg. acids may be used.

Aliphatic anhydrides. HENRY DREYFUS. Fr. 692,537, Mar. 21, 1930. Aliphatic anhydrides, particularly Ac_2O, are made by passing the vapor of aliphatic acids, particularly AcOH, in contact with a heated mass of Cu or other metal of good heat cond. Catalysts known to favor the reaction may be mixed with the Cu.

Aliphatic anhydrides. HENRY DREYFUS. Fr. 693,483, April 7, 1930. Aliphatic anhydrides, particularly Ac_2O, are prepd. by the thermal decompn. of aliphatic acids, particularly AcOH, in the presence of a catalyst composed of or contg. one of more anhydrides or acids of As or Sb or the salts of such acids, such as arseniates or antimoniates of Na, K or Ca. The preferred temp. is 350–700°. Cf. *C. A.* **25**, 971.

Ethyl alcohol and other oxygenated organic compounds. H. DREYFUS. Brit. 335,631, July 2, 1929. EtOH and other products such as higher alcs., esters, aldehydes and ketones are prepd. by heating MeOH vapor in the presence of catalysts comprising compds. of alkali or alk. earth metals in which these are the sole metallic compo-

nents (excluding Mg compds.) such as oxides, hydroxides and alcoholates of Na, K, Ba and Ca, preferably at 400–600°, although higher or somewhat lower temps. may be employed. Various details of app. and procedure are described.

Methyl and ethyl acetates. DEUTSCHE GOLD- UND SILBER-SCHEIDEANSTALT VORM ROESSLER (Otto Fuchs, inventor). Ger. 513,943, Jan. 16, 1927 and 514,744, Mar. 22, 1927. Addns. to 507,205. In applying the method of Ger. 507,205 (*C. A.* **25**, 524) to the esterification of crude pyroligneous acid, the acid is preliminarily purified by heating under pressure (513,943). This purification treatment may be effected in the presence of salts, *e. g.*, 20–40% of a bisulfate (514,744).

Benzanthrone, etc. IVAN GUBELMANN, ROBERT J. GOODRICH and EDWARD T. HOWELL (to Newport Chemical Corp.). U. S. 1,791,309, Feb. 3. In producing anthraquinone derivs. such as benzanthrone or methyl benzanthrone, a starting material such as anthraquinone or methyl anthraquinone is caused to react in concd. H_2SO_4 with a Cu salt such as $CuSO_4$ and a metal such as Zn or Al which is higher than Cu in the electromotive series (suitably at 25–30°).

3-Nitro-5-ketotetrahydronaphthalene. I. G. FARBENIND. A.-G. (Emil Laage, inventor). Ger. 515,111, Apr. 12, 1929. The anil of 5-ketotetrahydronaphthalene is nitrated and the product decompd. with dil. mineral acid. An example is given.

α-Naphthol. I. G. FARBENIND. A.-G. Fr. 693,596, April 9, 1930. α-Naphthol is prepd. by heating α-ketotetrahydronaphthalene with S at about 200°. A catalyst such as Se, finely divided Sn, ZnO, arsenious anhydride or diphenylguanidine may be used.

1,4,1',4'-Tetrahydroxy-2,2'-dianthraquinonyl. I. G. FARBENIND A.-G. (Robert E. Schmidt, Berthold Stein and Kurt Bamberger, inventors). Ger. 515,114, Sept. 22, 1929. Quinizarin is treated with piperidine or its homologs or analogs at atm. or slightly raised temp. An example is given.

1,4,4'-Trihydroxy-2,2'-dianthraquinonyl-3,1'-oxide. I. G. FARBENIND. A.-G. (Robert E. Schmidt, Berthold Stein and Kurt Bamberger, inventors). Ger. 515,115, Oct. 2, 1929. 1,4,1',4'-Tetrahydroxy-2,2'-dianthraquinonyl in nitronaphthalene or other nitro compd. of high b. p. is boiled for a short time. An example is given. Cf. preceding abst.

Triazine derivatives. I. G. FARBENIND. A.-G. Brit. 335,783, Oct. 31, 1928. See Ger. 501,087 (*C. A.* **24**, 4520).

Mercaptobenzothiazole, etc. IMPERIAL CHEMICAL INDUSTRIES, LTD., and K. H. SAUNDERS. Brit. 335,567, March 26, 1929. Mercaptobenzothiazole is prepd. by introducing a soln. of S in CS_2 mixed with $PhNH_2$ into a reaction vessel heated to 200–275° and under pressure, and allowing the mixt., on completion of the reaction, to overflow into a second chamber when it is drawn off. App. is described adapted also for other reactions of liquids and overflow of the reaction products.

β-Hydroxy-α-picoline. I. G. FARBENIND. A.-G. Brit. 335,818, Nov. 26, 1928. α-Picoline-β-sulfonic acid (which may be prepd. as described in Brit. 335,817) is fused with an alkali such as KOH. Production of an *azo dye* by coupling it with diazotized *p*-nitroaniline in Na_2CO_3 soln. is described.

Polymerized vinyl chloride. IWAN OSTROMISLENSKY (to L. A. Van Dyk). U. S. 1,791,009, Feb. 3. For obtaining the β-modification of polymerized vinyl chloride, the vinyl chloride is polymerized until the δ-modification is formed, followed by addn. of aniline, pptn. with alc. and dissolving in $C_2H_2Cl_4$.

Purpurin. HENRY R. LEE and IVAN GUBELMANN (to Newport Chemical Corp.). U. S. 1,790,932, Feb. 3. A soln. of 3-chloroquinizarin in concd. H_2SO_4 is heated at about 220° for a prolonged time (suitably about 20 hrs.).

Quinizarin. IVAN GUBELMANN and HENRY J. WEILAND (to Newport Chemical Corp.). U. S. 1,790,915, Feb. 3. In prepg. a quinizarin, a *p*-chloroaniline is diazotized in H_2SO_4, the diazo compd. thus formed, without isolation, is reacted upon in substantially anhyd. H_2SO_4 with phthalic anhydride in the presence of H_3BO_3 at a temp. of about 200° and this temp. is maintained until condensation is substantially complete, followed by cooling and diln. with water to ppt. the quinazarin compd.

Leuco indigo. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 693,469, April 7, 1930. Leuco indigo is made in a continuous manner by passing a paste of alk. indigo over a Ni catalyst on a rigid or semi-rigid support composed of a granular reticular or tangled mass, in the presence of H under pressure. A temp. of 120–140° is used and the catalyst may be activated with Al_2O_3.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Chemical properties of blood pigments and related substances. A. STHERMAN. *Chem. Weekblad* 27, 170–4(1930).—The general chem. and optical properties of hemoglobin and its derivs. are described, and the variations exhibited by various types of blood are discussed. B. C. A.

Philothione as hydrogenase. J. DE REY-PAILHADE. *Compt. rend. soc. biol.* 99, 1700–2(1929).—Egg white, dild. with an equal vol. of water, was used as a source of philothione; the addn. of S liberates H_2S in 30 min. The philothione formed contains the -S-S- linking characteristic of cystine. The reaction does not occur after heating with dil. acid or alk. media; further, the ppt. formed by heating does not give H_2S after the addn. of S. It is maintained that philothione is an enzyme. B. C. A.

The Spierer lens and what it reveals in cellulose and protoplasm. WILLIAM SEIFRIZ. *J. Phys. Chem.* 35, 118–29(1931).—The Spierer lens is an oil-immersion objective in which is inserted a mirror, smaller than the lens, which reflects all direct light coming into the objective. A diaphragm controls the admission of light. Scattered light is picked up by the lens around the mirror. The structure of cellulose and protoplasm as revealed by the Spierer lens is that of tiny rods or supermicelles arranged end-to end to form long parallel striae. F. E. BROWN

The chylomicron emulsion. S. DEW. LUDLUM, A. E. TAFT AND R. L. NUGENT. *J. Phys. Chem.* 35, 269–88(1931).—Chylomicrons are oil droplets in the blood. Their diams. are 1μ and smaller. That they are surrounded by a protective protein layer is indicated by: (*a*) their max. flocculation at p_H 4.8–5.2, (*b*) the reversal of their charges at p_H 4.8–5 and (*c*) coalescence to form larger droplets at a point in acid or alc. concn. at which protein would be salted out. Mixed serum albumin and globulin would behave in exactly this way when acting as protective layers on colloidal particles. The application of the Mudd interface technic gives results similar to those observed for fat globules in milk. These milk globules are believed to be surrounded by protein. The question of the assimilation and storage of fats and the behavior of lipoid droplets in clinical tests, as those for syphilis, make this an important subject for study. The known behavior in these fields is in accord with the assumption of a protein sheath. F. E. BROWN

The end point of tryptic action. J. TEMMINCK GROLL. *Pharm. Weekblad* 68, 109–21(1931).—A study is made of the factors which might be expected to influence the extent of hydrolysis of casein and gelatin by trypsin prepns. from hog pancreas. Ordinarily about 20% of the total N is converted in 1 week into amino N which can be titrated with CH_2O. After several weeks the conversion may be as high as 30%, but this further increase does not represent enzymic action since the control without enzyme behaves similarly. The enzyme does not become inactivated since it readily attacks fresh addns. of substrate. Moreover, the addn. of fresh enzyme does not increase the extent of hydrolysis. The final equil. is not appreciably influenced by the purity of the enzyme prepn., by variations in p_H, nor by the concn. of enzyme. No evidence could be obtained of the formation of an inhibitory substance (Northrop, *C. A.* 16, 1598), nor of an equil. due to the inhibitory effect of decompn. products. Addn. of another protease, *e. g.*, that of yeast, readily carries the proteolysis to a further stage after the tryptic digestion has come to a standstill. A. W. DOX

Proteolytic enzymes in the leucocytes of man. ERIK HUSFELDT. *Z. physiol. Chem.* 194, 137–65(1931).—Different types of leucocytes were examd. separately for their proteolytic enzymes. This is the first time that such expts. have been performed with a single variety of cell, since the organs previously studied, *e. g.*, spleen, liver and even normal blood, contain mixts. of cells. The enzyme material consisted of (1) exudates from acute inflammations where polymorphonuclear neutrophilic leucocytes are present almost exclusively, (2) cells from the blood of a patient with myeloid leucemia where granulocytes and their precursors are exclusively present, (3) cells from normal blood, (4) acute inflammatory exudates of rabbits which consist essentially of polymorphonuclear pseudoeosinophilic leucocytes corresponding biologically to the neutrophilic leucocytes of man. The substrates employed were casein, edestin and synthetic polypeptides, all in solns. in which the p_H was varied by the aid of buffers. Proteinase action was measured by pptg. with CCl_3CO_2H and Kjeldahl detn. of the uncoagulable

N before and after the expt. Peptidase action was detd. by Willstätter's titration with 0.05 *N* KOH in EtOH. In the glycerol ext. of leucocytes from the blood of a patient with myeloid leucemia, where practically all the cells belong to the myeloid system, 2 proteinases were found: a *cathepsin*, active between p_H 3 and p_H 7, showing optimal cleavage of casein at p_H 4.3 and of edestin at p_H 5.2, and a *trypsin* increasingly active from p_H 4.0 on. The cathepsin resembles that of organs and represents the actual autolytic enzyme found in all animal cells. In the autolysis of cells with $CHCl_3$ the trypsin is formed in increasing quantity with progressive destruction of the cells. In the cells from acute exudates (polymorphonuclear leucocytes) trypsin is so abundantly present as to obscure the cathepsin. Attempts to adsorb the trypsin on casein did not give a satisfactory sepn., since so much of the enzyme still remained in soln. that catheptic activity could not be demonstrated. Glycerol exts. of the leucocyte mixt. from normal blood contained a considerable quantity of *peptidases*. These showed a characteristic dipeptide cleavage like the enteric secretion. Alanylglycine was readily hydrolyzed at an optimum p_H of 7.2, while the optimum cleavage of leucylglycine at p_H 8.1 was only $^1/_3$ as great. Tripeptides gave the strongest cleavage, the optimum for alanylglycylglycine being at 7.3. Cleavage of the tetrapeptide, leucylglycylglycylglycine, was less pronounced though distinct. In the glycerol ext. of cells from myeloid leucemia (granulocytes) the same enzymes were present and in the same relative proportions. Certain of the enzymes of the polymorphonuclear leucocytes are bound to the so-called granula of the cells. These granula are droplets of a protein and their isoelec. points can be detd. with the aid of microscopic staining reactions. In different animals the granulations have different isoelec. points. These points, as also the dissocn. of the protein, coincide with the p_H activity curve of the proteinases. The isoelec. point of the pseudoeosinophilic granulations of rabbit leucocytes, *e. g.*, is at p_H 7.0 and the proteinase acts from 7.0 to 3.0. The neutrophilic granulations in the polymorphonuclear leucocytes of man have an isoelec. point at 4.5; the corresponding proteinase is increasingly active from p_H 4.0 into the alk. region. It is possible that the dissocn. of the protein present in the granulations dets. the p_H activity curve of the proteolytic enzyme likewise bound to the protein of the granulations.

A. W. Dox

The cephalin from human brain. II. The question of oxidation and purification of cephalin. Irvine H. Page and Margarete Bülow. *Z. physiol. Chem.* **194**, 166–90(1931); cf. *C. A.* **25**, 718.—In contact with the air cephalin undergoes an oxidative alteration, the progress of which can be followed by noting the decrease in I no. At the same time the values for C, H and N decrease. The P content remains const. and never increases. The neutralization no. rises. A change in all these values does not occur if the cephalin is kept under EtOH. Various prepns. of cephalin show the same relationship between I no. and elementary analysis. Cephalin, like lecithin, may be oxidized by atm. O and Fe as catalyst, and the addn. of AcOH is not necessary. The product thus obtained shows the same regularity in analytical values as that obtained by atm. oxidation Purification of cephalin with HCl by the Frankel and Neubauer procedure (*C. A.* **5**, 715) leads to an ash-free material, but in only 50% yield. The main losses are due to an EtOH-sol. product which does not differ from the EtOH-insol. cephalin with respect to I and neutralization no. but gives quite different analytical values. By repptn. of purified cephalin a certain sepn. of the complex can be effected. When Et_2O-EtOH is used, the component with lower I and higher neutralization no. may be centrifuged out, leaving the other component in soln. Repptns. in the presence of H_2O lead invariably to products with lower neutralization and higher I no.

A. W. Dox

Phosphatides. II. The highly unsaturated fatty acids of the phosphatides from various organs. E. Klenk and O. v. Schoenebeck. *Z. physiol. Chem.* **194**, 191–2 (1931); cf. *C. A.* **25**, 120.—The highly unsatd. C_{22} acid recently found in the cephalin fraction of brain occurs also in the lecithin fraction of brain and in the phosphatides of beef liver. The sepn. of the highly unsatd. acids from the total fatty acids was accomplished by the Li salt-MeAc method of Tsujimoto (*C. A.* **15**, 1227). The fatty acids were converted into the Me esters and fractionated in a high vacuum. The highest-boiling fractions were in both cases the most unsatd. Hydrogenation and sapon. yielded behenic acid. Bromination of the unsatd. acids from liver phosphatides gave an Et_2O-insol. product, the analysis of which was in fair agreement with $C_{22}H_{32}Br_8O_2$. Removal of Br and subsequent hydrogenation, however, converted it into a mixt. contg. behenic acid, but no arachidonic acid could be identified. The highly unsatd. C_{22} acid appears to be of wide distribution in phosphatides of animal origin.

A. W. Dox

Chemistry of enzymes, hormones and vitamins. FELIX HAUROWITZ. *Pharm. Presse, Wiss.-prakt. Heft* **1930**, 161–5.—A review of the chief members of these 3 groups. W. O. E.

Amylase protecting substances. IV. Protective action of infusions of yeast, malt and barley. HIROICHI NAKAMURA. *J. Soc. Chem. Ind., Japan* **34**, Suppl. binding 16–7(1931); cf. *C. A.* **25**, 1270.—Yeast juice, prepd. by plasmolyzing yeast with PhMe, then autolyzing with H_2O 24 hrs. and filtering, was found to have very little protective action against the inactivation of takadiastase by heat at 50°. Infusions of malt and barley, prepd. cold, then boiled and filtered, had a marked protective action but no activating action. **V. Isolation of the protective substances from proteases.** *Ibid* 18–9.—Solns. of papain, papayotin and pepsin, which had been found to have a protective action, were made alk. to p_H 11.5 with NaOH and KH_2PO_4 and allowed to stand. The clear solns. were then found to have no protective action, but the pptd. material was 10–30 times as active as the original protease. **VI. Isolation of the protective substances from peptones and malt and yeast infusions.** *Ibid* 19–20.—Yeast, malt and peptone solns., treated as in part V, gave similar results, the pptd. material having a very powerful protective action. **VII. The identification of the chemically pure protective substances.** *Ibid* 21–2.—The ash from the ppts. obtained in V and VI was also found to have a most powerful protective action. Expts. showed the action is due entirely to the Ca content. Conclusion: Amylase is an org. Ca compd. and its decrease in amylolytic power when heated is due to loss of combined Ca. L. E. G.

A unit of expression for the hemolytic index. A. WEIL AND D. M. LIPCHÜTZ. *Arch. ges. Physiol.* (*Pflügers*) **226**, 239–42(1930).—Sapotoxin is suggested as a standard for expressing hemolytic activity. The hemolytic index is expressed as the no. of mg. of sapotoxin whose activity is equiv. to 100 cc. of the soln. in question. A. G.

The reversibility of coupled reactions in biological systems and the second law of thermodynamics. DEAN BURK. *J. Phys. Chem.* **35**, 432–55(1931).—The object of this paper is to indicate the extent to which the applicability of the second law of thermodynamics to like processes has so far received direct exptl. support. In general crit. data do not exist. Two types of free-energy efficiencies are distinguished, *viz*, "machine free-energy efficiency," in which the work done in a given reaction is compared to the total free energy dissipated by the organisms in all of their life processes, and "second-law free-energy efficiency," in which the work done in a reaction is compared to the free energy dissipated by that reaction alone. Obviously, the 2 may differ greatly and it is the object to det. if the latter may ever exceed 100%. The reversibility of autotrophic reduction of CO_2 by H_2 in the case of *B. pycnoticus* (Rühland, *Jahrbuch. wiss. Bot.* 63, 321 (1924)) is practically perfect, when the extraneous energy consumed in the metabolic processes of the organisms is taken into account. On the other hand, the second-law efficiencies calcd. from available data on autotrophic CH_4 oxidation and heterotrophic nitrate reduction are low. Second-law efficiency calcns. may be useful in detecting impossible, improbable or incomplete exptl. biological data. H. F. J.

The specificity of animal proteases. XX. Mechanism of enzymic dipeptide cleavage. ARNOLD K. BALLS AND FRANZ KÖHLER. *Ber.* **64B**, 34–45(1931); cf. *C. A.* **20**, 3702; **21**, 2910; **23**, 4235; **24**, 3522.—Erepsin (I) from the intestines can be sepd. into 2 components, a polypeptidase (II) and a dipeptidase (III), proving the presence in the ereptic enzyme-complex of an independent dipeptide-splitting enzyme. I may be used to det. the action of III in cases where the substrate is not attacked by II. The purpose of the expts. of B. and K. was to det. the reaction mechanism of the enzymic dipeptide cleavage by the study of a no. of "aniline peptides," many of which undergo cleavage by III. Because their constitution and properties may be varied by introducing different substituents, they are valuable for the study of the mechanism of peptide hydrolysis. The enzyme apparently attacks the peptide first at the NH_2 group, and then at the NH group. The prepn. of I, II, III and the substrates used is described by B. and K. in detail. The substrates used were the following glycyl derivs.: aniline (IV), *o*-toluidine, *p*-toluidine (V), *o*-aminobenzoic acid (VI), *m*-aminobenzoic acid, *p*-aminobenzoic acid (VII), *p*-nitroaniline (VIII), *p*-chloroaniline, and *p*-nitroaniline *o*-carboxylic acid (IX). Since VII, VIII and IX undergo cleavage by I, but IV, V and VI do not, B. and K. conclude that the substituent group (COOH or NH_2) affects the acid character of the peptide linkage and thus of the NH group. Interference with the action of III by such substances as chloroacetyltyrosine and aceturic acid supports the theory that the NH group is the 2nd point of attachment for the enzyme. The cause of the interference is the attachment of the enzyme to the NH group. The cleavage of ordinary di- and polypeptides by I, II and III was also studied. Cleavage of all of the higher glycine peptides was difficult. Apparently the presence of several

glycine residues forms an unfavorable configuration for the action of II. **XXI. The causes of steric selection by enzymes.** ERNST WALDSCHMIDT-LEITZ AND ARNOLD K. BALLS. *Ibid* 45–8.—Of the 3 isomeric chloroacetylaminobenzoic acids only the *m*-compd. undergoes cleavage by the carboxy-polypeptidase from hog-pancreas, indicating that only in the *m*-acid does the spatial arrangement of the substituents permit the reaction of the enzyme with COOH. LOUISE KELLEY

Experiments on denatured proteins. HENRY F. HOLDEN AND MAVIS FREEMAN. *Australian J. Exptl. Biol. Med. Sci.* 7, 13–26(1930).—Denaturization of proteins causes an increase in $[\alpha]$ which varies with the degree of change, the treatment producing the change and its subsequent history. Ox globin, ox euglobulin, horse globin, sheep euglobulin and hen egg albumin were studied, giving the following values, resp., for native and denatured proteins, $[\alpha]_{6780}$, —13° (water soln.) and —72° (NaOH soln.), —44.8° (NaCl) and —67.7 (NaOH), —18° (water) and —71 (NaOH), —46.6° (NaCl) and —88.8° (NaOH), —31.1 (water) and —51.4° (NaOH). The pptn. by Hg salts is slight in soln. not near the isoelec. point, on account of a low degree of ionization. The denatured proteins, including casein, show a higher $[\alpha]$ in acid soln. than in alkali, and when denatured by alc., a lower $[\alpha]$ than when denatured by HCl. C. G. KING

Action of dilute formaldehyde solution on proteins and protein derivatives. MAVIS FREEMAN. *Australian J. Exptl. Biol. Med. Sci.* 7, 117–24(1930).—Proteins and their hydrolytic products were partially (25–70%) pptd. by treatment with 0.5% HCHO at 37° for 10 days. Slight changes in $[\alpha]$ and in soly. were produced, the products being readily sol. in dil. acids and alkalies. C. G. KING

The toxicity of blood which has been frozen. WILLIAM ALEX. OSBORNE. *Australian J. Exptl. Biol. Med. Sci.* 7, 223–8(1930).—Defibrinated dog blood becomes toxic to the donor when frozen and thawed and injected intravenously. Toxicity is thought to be due to a denatured protein. C. G. KING

Rabbit-liver glycogen and its preparation. MELVILLE SAHYUN AND CARL L. ALSBERG. *J. Biol. Chem.* 89, 33–9(1930); cf. *C. A.* 23, 4273.—Glycogen can be readily obtained from liver by the use of 3% CCl_3CO_2H to remove the proteins. Thus prepd. it contained between 0.20 and 0.18% of ash; P_2O_5 and traces of Ca and Fe were present in the ash. By hydrolysis the purity of this glycogen was shown to be from 96.4 to 99.6%; and the P content calcd. as P_2O_5 was 0.032%. Glycogen is readily "denatured" by heating it to 105°; its soln. is considerably less opalescent; it acquires very strong adhesive properties even to smooth glass surfaces and the port-wine color with I changes to pink as it vanishes instead of gradually fading out. A. P. LOTHROP

Neutral-red reaction. V. KOEHRING. *J. Morphol. Physiol.* 49, 45–138(1930).—In living organisms neutral red combines with enzymes wherever they exist in digestive lumina. When cellular vacuolar systems are permeable, enzymes can usually be demonstrated upon the mitochondria. Neutral red serves as an indicator of hydrolysis and synthesis within the cell; it indicates that eggs developing in the ovary show hydrolysis in the early stages and synthesis later. Developing spermatozoa are poorly nourished. C. M. MCCAY

Enzymes. JORGE W. HOWARD. *Semana méd.* (Buenos Aires) 1930, II, 1028–42.—The physiol. and pathol. action of enzymes is discussed and the therapeutic value of organ exts. is emphasized. A. E. MEYER

Influence of alcohols on the heat coagulation of protein solutions buffered with acetate. TORSTEN THORELL. *Biochem. Z.* 229, 1–15(1930).—Heat coagulation of protein occurs only within the p_H range of 4.7 to 6.2 in the presence or absence of alc. Alcs. exert an increasing inhibitory effect on the heat coagulation in the order: MeOH < EtOH < PrOH in the presence of an acetate buffer. The inhibition increases with the concn. of the buffer. At an alc. concn. of less than 15–20% the coagulum becomes partially or completely dissolved on heating, to be repptd. on cooling. Pure serum albumin or native plasma from the horse or man is similarly affected by the alc.-acetate mixt., but the coagulation of the ovalbumin is not thus affected. It is pointed out that the use of alc. in tests for the Bence-Jones protein may cause erroneous conclusions. S. MORGULIS

The multiple nature of the enzyme carrier in polypeptide hydrolysis by yeast maceration juice. Preparation of protein-free eluates which act exclusively on polypeptides. A. FODOR AND L. FRANKENTHAL. *Biochem. Z.* 229, 16–27(1930).—The kaolin adsorbate of yeast maceration juice can be leached out with an absolutely neutral soln. of glycine which yields an enzyme prepn. practically free from protein; this prepn. exerts a hydrolytic action on peptone, polypeptides and dipeptides. S. M.

Hydrolysis of proline polypeptides by yeast and pancreas extracts, also by pancreatin preparations. A. FODOR, MAX FRANKEL AND S. KUK. *Biochem. Z.* 229, 28–

40(1930).—The water-insol. residue of pancreatin prepns. which has a specific hydrolytic effect on dipeptides also hydrolyzes prolylalanine. The water-sol. fraction which hydrolyzes dipeptides only after prolonged autolysis has no effect at first on the prolylalanine, but after 140 hrs. hydrolyzes 29%. Fresh pancreas maceration juice hydrolyzes prolylalanine, this action being increased by dialysis. The yeast maceration juice produces this hydrolysis very effectively. S. MORGULIS

The effect of proteases on urease preparations. JOSEPH ZAKOWSKI. *Biochem. Z.* **229**, 41–84(1930).—The destruction of the Jack bean urease by papain and trypsin at 30° and 40° and a definite p_H has been studied. At 40° with a ratio of proteases to urease 6:1 as much as 70–80% of the enzyme was destroyed in 7 hrs. Even with a papain-urease mixt. in the proportion of 1:6 a loss of 52% of activity was observed under the same conditions after 7 hrs. However, it is not concluded from these observations that this indicates simply a protein hydrolysis either of the urease itself or of its carrier. The expts. exclude the possibility that the inactivation of the urease is due to a liberation by the proteases of inhibiting substances. The fact that factors which activate papain and trypsin (HCN and enterokinase) also increase the destructive effect on the urease argues in favor of the enzymic nature of the inactivating process. Erepsin had no influence on the inactivation of the urease prepn. The inactivation by the various buffers employed in these expts. was practically a linear function of time during 7 hrs. S. MORGULIS

Effect of irradiation by means of the quartz lamps in vitro on the protein fractions of the blood plasma. LADISLAUS KOSTYÀL. *Biochem. Z.* **229**, 100–8(1930).—The different protein colloids of blood manifest different sensitivities toward irradiation by quartz lamps under different disease conditions, the effect being much greater on plasma with stable than on plasma with labile proteins. The influence of this irradiation is min. on the blood plasma from normal individuals. The accelerating effect on the rate of red cell sedimentation is produced only over a limited range, beyond which the rate tends to be retarded. S. MORGULIS

Some comments on the paper by Genesius on the metabolic effect of the Gurwich-rays. A. GURVITCH. *Biochem. Z.* **229**, 109–14(1930).—Some important bearings of Genesius' work (*C. A.* **24**, 5795) are emphasized. S. MORGULIS

Studies on glycogenolysis. H. K. BARRENSCHEEN, JOHANNES PANY AND ROBERT BERGER. *Biochem. Z.* **229**, 196–215(1930).—Postmortem glycogenolysis of the liver for the first 2–4 hrs. does not proceed in a linear but in a step-like fashion; the splitting off of H_3PO_4 takes place in the same way, the curves of both processes coinciding so as to suggest that the 2 reactions are coupled. As source of the new inorg. phosphate there is not only the pyrophosphate fraction which is easily hydrolyzable by acid, but also the difficultly hydrolyzable fraction of the acid-sol. org. phosphate. Neither the addn of insulin *in vitro* nor preliminary insulin intoxication affects the glycogenolysis or the hydrolysis of H_3PO_4. A hexosemonophosphate ester is formed during glycogenolysis evidently at the periods when the sugar formation and hydrolysis of phosphate show a diminution. The Ba salt of the hexosemonophosphate obtained during the glycogenolysis of rabbit or dog liver is the same and corresponds to the biological or artificial hexosemonophosphate esters in reducing power and optical activity. S. MORGULIS

A protein-ethereal sulfate from the gastric mucosa. HERMANN MATHIS. *Biochem Z.* **229**, 263–4(1930); cf. *C. A.* **24**, 4548.—Protein-ethereal sulfate compds. have recently been isolated from the anterior hypophysis, liver and gastric mucosa. The protein moiety of the hypophysis compd. is a globulin and of its 9 S atoms 7 are in the form of H_2SO_4 and none is present as cystine. The compd. prepd. from liver is an acid and has no globulin properties, and of its 3 S atoms 2 are in the form of H_2SO_4, but the third S atom is not in the form of cystine. Insulin, on the contrary, contains no H_2SO_4 but much cystine. The gastric mucosa prepn. has the following characteristics: It contains only 1.67–1.77% S (liver prepn. 7.49–7.68% S; anterior hypophysis prepn. 2.16–2.49% S) of which 1.56% is hydrolyzable by HCl, so that the S is entirely in the form of the protein-ethereal sulfate combination. S. MORGULIS

Enzymes and light. XVII. The influence of the visible and ultra-violet light on the succinodehydrogenase of horse muscle. LUDWIG PINCUSSEN AND WADIM ROMAN. *Biochem. Z.* **229**, 281–90(1930); cf. *C. A.* **24**, 1130.—The effect of succinodehydrogenase in the reduction-oxidation system: succinic acid–fumaric acid is greatest at p_H 6.9, with a second max. at p_H 7.7. The enzyme is more stable in an acid medium than in an alk. medium. Illuminating succinodehydrogenase for 15 min. with ultra violet light causes a strong injury to the enzyme within the range of p_H 6.0 to 8.0, but not so much on the acid side. The enzyme is also injured by illuminating for 1 hr. with ordinary light, and it is claimed that the injury is greatest at the p_H of max. ac-

tivity of the enzyme. Apparently exposure to the light only for 30 min. stimulates the enzyme's activity. S. MORGULIS

Equilibrium between egg albumin, calcium and potassium salts. M. GIUFFRÉ. *Biochem. Z.* **229**, 296–310(1930).—Egg albumin freed by electroultrafiltration of electrolytes binds increasing amts. of $CaCl_2$, $CaSO_4$, $Ca(CSN)_2$ and of KCl from solns. of increasing concn. No satn. is attained up to salt concns. of 0.05 *N* or 500 milliequivs. per 100 g. albumin. At higher concns. the behavior is irregular. Although the curves obtained for 2 different samples of similarly purified egg albumin are of the same type, the abs. values for the 2 are different. Albumin binds Ca from $CaCl_2$ solns. of weak or medium concn. more than K from KCl solns., but although in weak concn. the difference may be 100%, the 2 values tend to come close together as the concns. increase. In the presence of both $CaCl_2$ and KCl the 2 are bound. Ca from $CaSO_4$ is bound 10% more and from $Ca(CSN)_2$ 25% less than from $CaCl_2$. S. MORGULIS

The postmortem lactic acid formation in the liver. EGON FENZ AND HANS POPPER *Biochem. Z.* **229**, 397–426(1930).—The lactic acid formed and diffused from liver pulp upon standing 2 hrs. was detd. by the colorimetric method of Dische-Laszlo, with hydroquinone and H_2SO_4 as reagents. The lactic acid of the guinea pig liver increases in the first 7 hrs. up to 400 mg %, but later the increase is less marked. In the human liver macerated in Ringer-$NaHCO_3$ soln. and kept in an incubator preserved with $CHCl_3$ there was no further increase in lactic acid after 7 hrs. and therefore the livers obtained 8 hrs. after death already attained the max. lactic acid production. In some 60 cadavers the av. amt. of lactic acid was about 0.30% (0.136 to 0.574%), and since among these were persons with diabetes, cirrhosis, acute yellow atrophy and various endocrine disturbances there was thus no evidence of any dependence upon the total glucide content of the liver. Also in livers which 10–33 hrs. after death remained for many hrs. without $CHCl_3$ at 37° either in $NaHCO_3$ or in Na_2HPO_4, even with the addn. of glucose, there was no further increase in the lactic acid. Expts. on the livers from guinea pigs show that shortly after death the lactic acid formation is considerable, becoming somewhat less after 2 hrs. and very much less after 4 hrs., almost ceasing after 7 hrs. There was no difference whether $NaHCO_3$ or Na_2HPO_4 was used in the Ringer soln. Nor could the addn. of glucose, levulose or of glycogen cause any alteration, and only occasionally was there an irregular increase in the lactic acid upon the addn. of hexosediphosphate. Otherwise the max. value of 500 mg. % was never exceeded. In animals with a particularly low glycogen content of the liver the max. formation of lactic acid fell below this value. Similar results were obtained in studies on the kidneys. The results of the lactic acid formation in practically all organs of 2 human cadavers and of 2 guinea pigs are tabulated. S. MORGULIS

The cleavage of tyrosine and tryptophan from casein by papain activated by hydrocyanic acid. THEODOR LEIPERT AND IRMGARD HÄFNER. *Biochem. Z.* **229**, 427–32 (1930).—Only 47% of the total N of casein is hydrolyzed as amino N in 12 days' digestion by papain-HCN. Tyrosine is set free entirely in proportion to the total amino acid cleavage, and tryptophan is only more or less proportional to the total hydrolysis. Under the combined action of papain-HCN and trypsin for a week 71% of the total N is hydrolyzed as amino N, but the hydrolysis of tyrosine and tryptophan by the 2 enzymes together seems to be unaffected. S. MORGULIS

Studies on tobacco enzymes. CARL NEUBERG AND MARIA KOBEL. *Biochem. Z.* **229**, 455–63(1930).—In the present-day methods of prepn. roof-dried tobacco is passed through a flume with a gradually rising temp., for the purposes of removing the H_2O. In the zone of max. heat the temp. reaches 100°. The entire passage occupies 60 min. It was found that the tobacco enzymes do not lose their activity in this process. The following enzymes were studied: amylase, invertase, phosphatase, pectase, glycolase and ketonaldehydemutase. S. MORGULIS

A model for studying pectase. CARL NEUBERG AND CLARA OSTENDORF. *Biochem. Z.* **229**, 464–6(1930).—The action of pectase may be represented as follows: Under the influence of this hydrolyzing enzyme upon probably the acid Me ester of a complex polybasic glucidic acid (pectin), the MeOH is split off while the poorly sol. Ca and Mg salts of the pectic acid form a gelatinous ppt. For better investigation of the action of the pectase a substrate of definite chem. composition, namely, the Ca salt of methyl-*d*-tartaric acid, is substituted for the pectin whose compn. is highly variable. This substance under the influence of pectase gives MeOH and the sparingly sol. Ca tartrate. S. MORGULIS

Studies in comparative biochemistry. VII. Chemistry of the special saké yeast. JUN-ICHIRO SAGARA. *J. Biochem.* (Japan) **12**, 459–71(1930); cf. *C. A.* **20**, 3745.—In 2 strains of saké yeast there was a close chem. resemblance both in the inorg. and

org. compn. No lecithin was found but a phosphatide was bound, which because of its high N content must be either a tri- or diamino-monophosphatide. The presence of a pentose was proved, and a substance related to bioses was isolated in pure cryst. form. Arginine, histidine, lysine, phenylalanine, proline and valine were identified, the phenylalanine and proline being the predominant components of the protein. The nucleic acids of both strains are distinguished by their low N and P contents. Both types of yeast contain amylase, esterase, glycerophosphatase, pepsin and trypsin. Data are also recorded on the inorg. compn. S. MORGULIS

The properties of the biochemical constituents, the proteins in particular, in anhydrous solution. JEAN LOISELEUR. *Compt. rend.* **191**, 1477–9(1930).—In aliphatic solvents, biochemical substances form true, not colloidal, solns. They manifest certain chem. properties: (1) they are not frothy; their viscosity is less than aq. solns. of the same concn.; they are optically clear, not pptd. by a formic soln. of the ions Na, K, Mg, Fe, Cr or by tannin, MeOH, $CHCl_3$, pyridine or cyclohexanol. (2) Addn. of water to an aliphatic soln. of protein forms a colloidal dispersion which shows a Tyndall effect, the micellar state, adsorption, and flocculation. (3) Casein and keratin, in aceto-formic soln. and in presence of HCl and HNO_3, form a nitration deriv. having colloidal properties. N. M. NAYLOR

Growth factor in plants. HANS V. EULER, MARGARETA RYDBOM AND HARRY HELLSTRÖM. *Svensk. Kem. Tids.* **42**, 277–81(1930)(in German).—Petr. ether exts. of sprouts examd. spectrographically showed bands at 533, 497, 447 and 424. Distd. at 150° and 0.02 mm. Hg they gave bands at 256 and 325. A distillate from a carotenoid from swordfish liver had a band at 325 and Moore reports 328 for a rat liver fraction (*C. A.* **24**, 5343). A. R. ROSE

Membrane phenomena in living matter: equilibrium or steady state. A. V. HILL. *Trans. Faraday Soc.* **26**, 667–78(1930).—The difference in f. p. between the white and yolk of hen's eggs, observed by Straub (*C. A.* **23**, 3482), is confirmed. Since it persists in an atm. of H the oxidative mechanism at the membrane postulated by Straub for opposing the osmotic pressure cannot occur. The p. d. between inside and outside of muscle or nerve is also far greater than can be accounted for on the Donnan equil basis. The widespread occurrence of such steady states, maintained by the expenditure of energy, is held to indicate their biol. importance. K. V. THIMANN

The state of water in colloidal and living systems. ROSS AIKEN GORTNER. *Trans Faraday Soc.* **26**, 678–704(1930).—The work of Newton and Gortner (*C. A.* **18**, 2543 3205) and that of Robinson (*C. A.* **23**, 910, 1180) on winter hardiness are reviewed in relation to the general problem of "bound" water in the cell, and are compared to similar phenomena with inorg. gels and proteins. A discussion is also given. K. V. THIMANN

The p_H-stability regions of the proteins. T. SVEDBERG. *Trans. Faraday Soc* **26**, 740–4(1930); cf. *C. A.* **25**, 530.—Electrophoresis measurements show that the isoelec. pt. of proteins is not identical with the point of min acid- and alkali-binding, but is identical with the soly. min. The method can be used to sep. mixts. of proteins, since mutual neutralization does not occur. The isoelec. pts. detd. in 0.02 *N* NaOAc buffer are: ovalbumin 4.55, serum albumin 4.88, R-phycoerythrin 4.25, C-phycocyan 4.76, hemocyanin (*Helix*) 5.05, Bence-Jones protein 5.20. A summary of the results of sedimentation detns. is given. K. V. THIMANN

The solubility of proteins. E. W. J. MARDLES. *Trans. Faraday Soc.* **26**, 750–60 (1930).—The soly. in water of Coignet's gelatin varies with the amt. of the solid phase, and is greater when detd. by cooling sols than by soaking gelatin in cold water. It increases sharply at 26°, is diminished by washing, and is increased by the presence of HOAc, $HCONH_2$, urea and other org. compds. It is concluded that gelatin is heterogeneous (cf. Schryver and Thimann, *C. A.* **22**, 968); from the corresponding behavior of blood albumin a similar conclusion is drawn. K. V. THIMANN

Biological significance of the physical state of lyophilic colloids. F. F. NORD. *Trans. Faraday Soc.* **26**, 760–8(1930).—A summary of the work (cf. *C. A.* **22**, 4544, **23**, 5475) in which increase of zymase activity on treatment with C_2H_2 and C_2H_4 is correlated with increase of surface tension and decrease in viscosity of cell-free zymase solns. Corresponding surface tension and viscosity phenomena with solns. of albumin or Na oleate indicate surface adsorption of these gases, and also of N_2O, on colloids, leading to protective action and hence increase of enzymic activity. K. V. T.

Phase rule equilibria of horse serum globulin. JAMES W. MCBAIN AND ELOISE JAMESON. *Trans. Faraday Soc.* **26**, 768–9(1930).—The phase diagram for globulin prepd. by Svedberg's method, water and Am_2SO_4 at p_H 6.0 at 40° is given. "It appears that globulin solns., euglobulin and pseudoglobulin are but 3 phase of a system

of the same mother substance, dehydrated globulin—solns. of globulin being the ordinary isotropic soln., while euglobulin and pseudoglobulin are liquid cryst. phases, or a liquid and glass which are slightly doubly refracting." K. V. THIMANN

The structure, behavior and physiological characteristics of vertebrate cells cultivated in vitro. H. B. FELL AND E. N. WILLMER. *Trans. Faraday Soc.* **26**, 772–9 (1930).—A general lecture on the technic of tissue cultures and their physiol. behavior. K. V. THIMANN

Surface structure in the integration of cell activity. RUDOLPH A. PETERS. *Trans. Faraday Soc.* **26**, 797–807(1930).—The importance of interface reactions in detg. the activities of the cell is discussed. The interfacial tensions of palmitic, capric and erucic acids in benzene solns. against phosphate buffer show a sharp fall at about p_H 6 continuing to p_H 9.5. Adsorption of weak acids and bases on purified charcoal follows closely the dissocn. curves, the undissocd. mol. being the most adsorbed (Phelps and Peters, *C. A.* **23**, 5080). The pptn. of phosphotungstates of histamine and other bases is also a function of p_H, histamine being pptd. sharply at p_H 7.8 and on the acid side. The presence or absence of a single H ion is calcd. to be of considerable importance in detg. the reactions occurring in bacterial cells. A theory of mosaic cell structure, involving mobile chains of liquid crystals a few mols. thick, and orientating all substances in the cell, is developed. K. V. THIMANN

The isoelectric point of cells and tissues. HANS PFEIFFER. *Trans. Faraday Soc.* **26**, 822–36(1930); cf. *Protoplasma* **11**, 85(1930); *Biol. Reviews* **4**, 1–40(1929); and *C. A.* **23**, 3725. K. V. THIMANN

Decrease in the activity of β-glucosidase of emulsin of almonds in the course of successive syntheses of β-methylglucoside. M. BRIDEL AND N. JOANID. *J. pharm. chim.* [8], **12**, 337–9(1930).—A mixt. of 3 g. emulsin and 150 g. dextrose in 500 cc. of 70% MeOH was continuously rotated for 8 days, *i. e.*, until the optical rotation of the soln. became const. (42°40′). The emulsin was then collected, washed with 90% alc. and dried *in vacuo*. Only 2 g. was obtained. The process was repeated 6 times with the recovered quantity of emulsin and 50 times its wt. of dextrose in each case. The following wts. of emulsin were recovered: 1.2, 1.2, 1.0, 1.0, 1.0, 1.0 g. The 7th synthesis required 19 days to reach equil., and in each of the 7 cases, about 77% of the dextrose became combined. During equal periods of time in the 7 expts., the activity of β-glucosidase steadily diminished. Thus, measured by time, emulsin lost more than half of its activity. Nevertheless, having acted in these expts. for 3 months on 350 times its wt. of dextrose to cause 77% of it to form β-methylglucoside, it was still active enough to complete the last synthesis in 19 days. Mech. rotation shortened the time of these expts. materially. Also in *Bull. soc. chim. biol.* **12**, 931–3(1930). S. WALDBOTT

Hydrolysis by emulsin of 2 glucosides not considered hydrolyzable by this enzyme: asebotoside (asebotin) and phlorhizoside(phlorhizin). M. BRIDEL. *J. pharm. chim.* [8], **12**, 385–95(1930).—Contrary to the accepted belief, asebotoside (cf. Bourquelot and Fichtenholz, *C. A.* **6**, 1207) and phlorhizoside (cf. Johnson and Robertson, *C. A.* **24**, 1865), which are *l*-rotatory glucosides, are hydrolyzable by emulsin of almonds, yielding in each case *d*-glucose and a nonglucidic product insol. in water. Both glucosides therefore belong to the class of β-glucosides, *i. e.*, they are hydrolyzable by β-glucosidase. Twenty-five references are given. Also in *Bull. soc. chim. biol.* **12**, 921–30 (1930). S. WALDBOTT

Keijo Journal of Medicine (*New journal*). Published about quarterly by the Medical Faculty of the Keijo Imperial University, Kejio, Chosen, Japan. Vol. 1, No. 1 appeared Feb. 28, 1930. This journal replaces *Acta Medicinalia in Keijo* which was discontinued at the end of Vol. **12**, 1929.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

The antineuritic vitamin (preliminary communication). A. G. VAN VEEN. *Rec. trav. chim.* **49**, 1178–9(1930).—According to the method of Jansen and Donath (*Proc. Acad. Sci. Amsterdam* **29**, 1390(1926); cf. *C. A.* **20**, 2005) a product which contains about

20% of the vitamin may be easily obtained, the further purification being, however, very difficult and giving only 50–100 mg. of the pure vitamin from 100 kg. rice polishings after a few months' labor. Attempts have been made by Guha and Drummond (*C. A.* **24**, 1140) and by Williams, Waterman and Gurin (*C. A.* **24**, 4535) to obtain larger yields but without success; the technic of Jansen and Donath for the purification of the 20% product had to be modified profoundly in order to get higher yields. After having studied the products which accompany the vitamin in the 20% product, the author has now succeeded in getting 140 mg. of the cryst. vitamin from 75 kg. rice polishings; this product was, however, not pure, but could be purified by recrystn. The 20% product may be freed from several physiologically active compds. by treatment with acid chlorides or, even better, with sulfonyl chlorides, which leave the vitamin itself unchanged, and this may be purified further with the double salts of Pt or Cd chloride. It was found also that the Pauly reaction with diazotized sulfanilic acid is fainter the purer the vitamin. This fact was confirmed by Jansen (private communication). C. F. VAN DUIN

An improved design of the Van Slyke apparatus for the estimation of amino nitrogen. SIDNEY J. FOLLEY. *Biochem. J.* **24**, 961-4(1930). BENJAMIN HARROW

An apparatus for rotating serum-antigen mixtures in the Kline test for syphilis. PHILIP L. VARNEY. *Am. J. Pub. Health* **21**, 65–9(1931).—An electrically driven device is described, which mechanically mixes by rotation the serum-antigen mixt. As many as 6 slides (2″ × 3″) are accommodated at one time. The rotary speed of the app. has been arbitrarily set at 120 r. p. m. through an arc of ½″ radius. The app. may be connected to an elec. timing clock, thus relieving the technician of the necessity for timing the period of rotation, resulting in a greater uniformity of results and a saving in time necessary to perform the tests. J. A. KENNEDY

Colorimetric method for determining silicon. EARL J. KING. *Bull. soc. chim. biol.* **12**, 903–9(1930); cf. *C. A.* **23**, 405; **25**, 662.—The phosphate error in Isaacs' method (*C. A.* **18**, 3199) is pointed out and a modification proposed to avoid it. C. G. K.

C—BACTERIOLOGY

CHARLES B. MORREY

Vital conditions of ferruginous bacteria. (MLLE.) I. TUROWSKA. *Bull. intern. acad. polonaise* **1929B I**, 255–82.—Fe bacteria are found in certain wells and other waters of Poland in which the Fe content is usually greater than 2 mg. per l. and the reaction is between p_H 5.88 and 7.60. Large concns. of salts appear to be unfavorable. The bacteria are able to withstand temps. down to 0°. B. C. A.

Disinfecting properties of chloropicrin. A. SMORODINTZEV. *Z. Desinfektion* **21**, 169–72(1929).—Chloropicrin has a high penetrating power for porous materials. Its disinfecting power at 38° is double that at 4°. Spore-forming bacteria are very resistant. B. C. A.

Studies on the Coccaceae. XVI. Genus Leuconostoc. G. J. HUCKER AND CARL S. PEDERSON. N. Y. Agr. Expt. Sta., *Tech. Bull.* **167**, 3–80(1930); cf. *C. A.* **23**, 629.—A biochem. study was made of 166 strains of low acid-producing types of streptococci (*Leuconostoc*) from slimy sugar solns., fermenting vegetables and from milk and milk products. All members of the genus *Leuconostoc* produce approx. 45% *l*-lactic acid from glucose, 20% CO_2 and 25% of volatile products, including AcOH and EtOH. In addn., the members of this group produce mannitol from fructose and a levulan or dextran from sucrose. In morphology, the genus *Leuconostoc* lies intermediate between the streptococci and the lactobacilli. Secondary characters used for recognition of species within the genus are the fermentations of pentoses and sucrose. Three species are well defined. *L. mesenteroides* ferments pentoses (arabinose or xylose) and sucrose, produces slime in sugar solns., and is generally found in fermenting vegetable material and in sugar solns. *L. dextranicus* ferments sucrose but not pentoses, produces a moderate amt. of slime in sugar solns. and may be assocd. with either vegetable or with dairy products. *L. citrovorous* fails to ferment either sucrose or the pentoses, produces no slime in sugar solns and is generally assocd. with milk or milk products. C. R. FELLERS

Staining bacterial flagella. R. P. LEOPOLD. *Sci. Agr.* **11**, 232–7(1930).—A modified Zettnow technic is preferred. C. R. FELLERS

The physiology of the acetic acid fermentation. I. The importance of cytochrome in the physiology of cell respiration. HIROSHI TAMIYA AND KIYOSHI TANAKA. *Acta Phytochim.* **5**, 167–211(1930).—The AcOH fermentation with *Acetobacter pasteurianus* was studied in a special app. It consists of 2 cylinders carefully ground into each other providing a piston-like air-tight closure. The outside cylinder is provided with an opening and a two-way stopcock. A series of 10 such cylinders is gently shaken on a machine. By this arrangement samples of both the gas and the fermentation mixt. can be taken. It was found that quinone can also be used as a H acceptor for the AcOH fermentation instead of O. The extent of the fermentation is largely independent of the amts. of O. CO does not influence the quinone fermentation while it hinders noticeably the O_2 fermentation. In the presence of light this effect is markedly ruled out The indophenol reaction of the AcOH bacterium is also hindered by CO more so in the dark than in the light. Toluene was found to retard strongly the O_2 fermentation even when the O_2 amts. were large; the quinone and methylene blue-fermentation, however, is not influenced. While the indophenol reaction of the AcOH bacterium as well as yeast is also retarded by toluene, *Lactarius* oxidase seems to be indifferent to its action. It furthermore was shown that the normal functioning of cytochrome is disturbed by the addn. of toluene and quinone, but is resistant toward methylene blue. The phenomena encountered are explained by assuming that cytochrome plays an important role in the O_2 fermentation of the AcOH bacterium and the normal O_2 respiration. Cytochrome is the "O_2 pressure regulator." The equation $Q' = R' C_A$ (Q' = extent of fermentation, R' = activity of the oxidizing enzyme system, C_A = concn. of the acceptor substance present on the surface of the enzyme) is given and the process discussed theoretically. The exptl. findings seem to agree with the theory of K. Shibata and H Tamiya (*C. A.* **24**, 3533). E. G.-F.

D—BOTANY

THOMAS G. PHILLIPS

Piceoside of black willow bark. M. BRIDEL AND J. RABATÉ. *Bull. soc. chim. biol.* **12**, 332–41(1930).—The extn. of the glucoside (see *C. A.* **24**, 4070) is described. B. C. A.

The action of radium on the germination of seeds. G. MEZZADROLI AND E. VARETON. *Atti accad. Lincei* **12**, 73–80(1930); cf. *C. A.* **24**, 5336.—A variety of seeds (cereals such as oats and corn; legumes such as peas, beans, soy) were exposed to the action of the same quantity of Ra at the same distance for 5 min., 30 min. and 3 hrs. The seeds were then planted and the relative growth was noted. Five min. is enough to stimulate growth somewhat; 30 min. has the max. effect, while with 3 hrs., growth is retarded. If ½ the amt. of Ra was used, 5 times the length of exposure was necessary. Therefore, Ra has a stimulating effect up to a certain period of exposure, beyond which the seeds are harmed. The stimulation is apparently permanent as seeds planted 2 months

after exposure showed the same accelerated growth as seeds freshly exposed for the same period of time. A. W. CONTIERI

Bibliography of Aspergillus, 1729 to 1928. HIROSHI TAMIYA AND SHINKICHI MORITA. *Botanical Mag.* (Tokyo) **43**, No. 506 to **44**, No. 524. pp. 204(1929–30); cf. *C. DOX

Researches in ionic interchange between yeast cells and salt solutions. PAUL GENAUD. *Ann. physiol. physicochim. biol.* **6**, 240–330(1930); cf. *C. A.* **25**, 316.—When yeast cells are placed in solns. of dissociable salts, there is a rapid interchange of cations within a few min. between the cellular membrane and the surrounding fluid; the metal begins to penetrate the cell interior within about 10 min., complete equil. being reached in about 60 min. Vital staining by basic dyes is due to just such a cationic interchange between the membrane and the surrounding fluid. The *total* cation content is a fairly const. quantity, characteristic for a yeast cell under definite conditions of growth. Although the cationic interchange usually concerns equimol. quantities, with some metals (*e. g.*, Ag) there is an enormous absorption not conditioned by a simple interchange, but by other forces (*e. g.*, reduction of the Ag^+ to Ag). In cases of simple diffusion (K^+, NH_4^+, Pb^{++}) the vacuoles contain approx. half as much of the absorbed cation as the membrane. Dead yeast cells can take up 4 times as much Pb as living cells, probably because of the liberation of free acids. Corresponding to their slight Na^+ content, the cells are impermeable to Na^+, possibly on account of the fact that the hydrated ion cannot pass through the pores of the cell membrane. The enormous avidity of the cell for Ag^+ is conditioned by the fact that the latter is reduced by an as yet uncharacterized substance in the cell interior. There is an extensive bibliography. H. E.

Effect of spiral ringing on solute translocation and the structure of the regenerated tissues of the apple. L. H. MACDANIELS AND OTIS F. CURTIS. Cornell Agr. Expt Sta., *Mem.* **133**, 3–31(1931).—Trunks of young apple trees were ringed by removing narrow strips of tissue extending twice around the trunks spirally. In some cases the *phloem* and outer tissues only were removed, but in others the outer annual ring of *xylem* also was cut out. The effect of this ringing upon solute translocation was studied by making N analyses and catalase detn. on the leaves. The structure of the regenerated tissues was studied by sectioning and microscopic examn. Lateral transfer of solutes and of food substances is relatively slow, though it does occur when forced by spiral ringing. Foods from above and nutrient salts from below tend to move in straight lines parallel to the long axes of the conducting elements. When the trunk is spirally ringed and nitrate is added to the soil, N movement to branches immediately above the end of the spiral is greatly reduced as in a completely ringed trunk, whereas movement to those branches on the side not obstructed by this upper end of the spiral is normal as in the check trees. The phloem is the more important tissue involved in translocation, since the effect of cutting the phloem alone was the same as when both xylem and phloem were cut. There is a close correlation between high N content and high catalase activity of the leaf tissues of all trees examd. The conducting tissues formed by the cambium subsequent to the ringing changed their orientation so that the long axes of the elements were parallel to the spiral. After the new tissues were formed, the localized effects of the ringing upon solute transfer to the leaves on the tree top disappeared. Cambial growth is made in response to the coming together of the food from the leaves and the nutrients from the roots. The position of greatest thickening of the xylem is detd. more by the food supply than by the nutrient salts. The change in the orientation of the cambium is detd. by a change in the direction of the movement of foods and of nutrients, or possibly something of the nature of an elec. polarity may be a factor in the orientation. The general conception that lateral conduction of food and of nutrients is slow, that these substances move in straight lines parallel to the long axes of the vascular elements, and that cambial growth is a response to the coming together of the streams of food and nutrients is valuable in explaining plant response in practical problems of propagation, grafting and pruning. The possible bearing of this conception of greatest growth activity upon the practice of tapping trees for *oleoresin* is discussed. C. R. FELLERS

Growth behavior and maintenance of organic foods in Bahia grass. W. A. LEUKEL AND J. M. COLEMAN. Fla. Agr. Expt. Sta., *Tech. Bull.* **219**, 5–56(1930).—Except for the first year, frequent cuttings yielded more top growth and greater wt. than a single cutting at mature growth. The top growth from plants cut frequently retained more of a vegetative growth condition, more uniform % of N and a narrower carbohydrate-N ratio than plants grown to maturity. The latter gradually decreased

in % N, were less vegetative and gradually showed a wide carbohydrate-N relation assocd. with increased reproduction. Increased vegetative top growth production on plants was assocd. with a variation in % and quantity of org. foods in the stolons. During periods of slow growth such stolons again increased in wt. and quantity of reserve foods. Heavy seed production was assocd. with some decrease n org. foods in stolons but such foods again increased in quantity thereafter. The elaboration of org. foods by the more horizontal leaf area not removed by cutting appeared to be sufficient for the growing needs of the plant. C. R. FELLERS

Carbohydrate metabolism of Stipa pulchra. ARTHUR W. SAMPSON AND EDWARD C. MCCARTY. *Hilgardia* **5**, 61–100(1930).—The growth cycle of *Stipa pulchra* is an orderly process characterized by periodicity in that intervals of rapid growth alternate with intervals of depression in the growth rate. An inverse correlation existed between the annual march of carbohydrates and the growth rate. Accumulation of foods is related to low or to declining growth velocity, and is most active near the close of the annual growth cycle. Practically complete accumulation of carbohydrate foods occurred where 43 50% of the total annual herbage yield was produced prior to the peak in the growth rate Clipping or grazing had little effect on the total herbage yield and did not prevent the accumulation of max. amts. of carbohydrates in the latter part of the growth cycle. The herbage of *Stipa pulchra* on the range retains its succulency for 9 10 months. C. R. FELLERS

Experiments in forcing gladioli. F. F. WEINARD AND S W. DECKER. Ill. Agr. Expt. Sta., *Bull.* **357**, 345–61(1930).—The most desirable corms for forcing are those over 1½ in. in diam. Storage at 5 8° early in the season and at 20–1 for a short time previous to planting gave the best results. *Ethylene dichloride* and *ethylene chlorohydrin* forced the corms into early growth. The chem. treatment, however, is not yet well standardized and sometimes causes injury. C. R. FELLERS

Some effects of defoliation on fruit spur composition and fruit bud formation in the Oldenburg apple. G. F. POTTER, H. R. KRAYBILL, S. W. WENTWORTH, J. T. SULLIVAN AND P. T. BLOOD. N. H. Agr. Expt. Sta., *Tech. Bull.* **41**, 3–27(1930).—All the blossom buds were removed when in the "pink" stage from 3 heavily blooming Oldenburg apple trees. Every second spur on 2 similar trees was deblossomed so that along each branch deflorated spurs alternated with those blossoming and setting fruit. Four trees from which no blooms were removed served as controls. The wt. and the compn. of the developing fruits were detd. at 10 dates between the period of petal fall and harvest. The compn. and the fruit-bud formation of bearing spurs from the control trees and of deflorated spurs from the other 2 treatments were studied. The increase in dry wt. of the individual fruits followed the usual logarithmic curve of growth, the rate of increase reaching a max. in the second and third weeks in July. At this period each apple absorbed about 1 mg. of N daily and about 300 mg. of carbohydrate. Throughout June and July the N content of the bearing spurs was much higher than that of either of the other 2 types, and also was considerably higher on a % basis than the N content of the fruits. The starch content of bearing spurs and the adjacent 50% deflorated spurs was similar and lower throughout the season than in the 100% deflorated spurs on non-fruiting trees. The sugar-starch equil. of the fruit was independent of that in the spur to which it was attached, and sugars in the fruit reached a concn. several times that in the spur. The ash content of the bearing spurs was comparatively low; that of the 2 types of deflorated spurs was essentially similar. No difference large enough to be detd. existed among the 3 types of spurs in content of free reducing substances, sucrose, P, phlorhizin, acid hydrolyzable substances and total carbohydrates. The compn. and fruit-bud formation of adjoining spurs are materially altered by the presence of blossoming and fruiting spurs. No critical evidence is afforded, however, as to the fundamental nutritional causes underlying fruit-bud formation. C. R. FELLERS

Relation of hydrophilic colloids to hardiness in the apple as shown by the dye absorption test. STUART DUNN. N. H. Agr. Expt. Sta., *Tech. Bull.* **44**, 3–18(1930).—Results are compared both to general experience and opinion as to the ranking of varieties and to a freezing test by solid CO_2. Results of tests for 5 yrs. on 1-yr.-old twigs gathered each fall for 22 different varieties grown in Iowa and of direct freezing tests for 2 of these yrs. show a correlation of about 65% of the varieties compared to field experience, and 55% in 1 series and about 80% in the other on the basis of the parallel freezing test. The freezing tests agree with each other to a less extent. A marked consistency in the varieties not in agreement, as shown by a comparison of the various tests, and their variations in position in the different series, suggest that a lack of constancy in hardiness in any variety is assocd. with its failure to respond consistently or correctly

to any hardiness test. A similar conclusion is drawn from results on N. H. varieties. Similar tests on 12 N. H. varieties show a correlation between the dye test and either of the other standards of from 60 to over 90%. A large no. of freezing tests were made, distributed throughout the dormant season, which offered a wider basis of comparison. A marked trend toward a closer agreement was shown in the series gathered later in the season. Conclusion: The dye absorption test is not sufficiently consistent to be used in a quick, conclusive detn. of hardiness in the apple, but possibly in conjunction with other tests, such as the freezing test, will serve to differentiate between the hardiness of unknown varieties which are rather const. in that respect, if a sufficient no. of detns. is made. Some other factors besides the hydrophilic colloids are apparently partially responsible for hardiness, at least in ligneous plants like the apple. C. R. F.

Development and ripening of peaches as correlated with physical characteristics, chemical composition and histological structure of the fruit flesh. II. Histology and microchemistry. R. M. Addoms, G. T. Nightingalf and M. A. Blake. N. J. Agr. Expt Sta., *Bull.* **507**, 3–19(1930); cf. *C. A.* **24**, 5333.—Elberta and Shipper Cling varieties were used. Microchem. tests showed a gradual decrease in *protopectin*, *cellulose* and *hemicellulose* content as ripening proceeded. The change from hard-ripe to soft-ripe occurs within a very short time and is accompanied by profound changes in the cell walls, many of which completely break down and become disorganized. Comparisons made on fruits from a highly veget tive tree and a less vegetative tree, higher in carbohydrates, showed no chem. differences for the first 75 days after bloom. However, the latter contained more tannins and oxidases, but no histological differences were noted. Differences in microchem. and histological reactions in the Elberta and Shipper Cling varieties were evident only in the final stages of ripening. The non melting quality of ripe fruits of Shipper Cling variety is assocd. chiefly with the retention of a high content of insol. protopectin in the cell walls of the flesh. A bibliography is given. C. R. Fellers

Studies on tree root activities. III. G. H. Harris. *Sci. Agr.* **11**, 191–9(1930); cf. *C. A.* **24**, 5054.—The immediate influence of top pruning on root respiration is due to the injury caused. On the other hand, the immediate influence of injecting sugar in the top on root respiration is due to the injections stimulating bud activity. The buds in turn stimulate root respiration. In the nutrient solns. used, where all the nutrients were readily available, the amt. of CO_2 excreted by the root and absorption appeared to have little relation. Absorption seemed more closely related to the activity of the growing top. Cutting off the light from the growing tops reduced the amt. of root respiration. When transpiration is high, the CO_2 excreted by the roots is lower than if transpiration were low at this time. Some of the CO_2 produced during root respiration is apparently swept up to the tops during a time of high transpiration and consequently less is excreted by the root than if transpiration were low. C. R. F.

Sparassole in the roots of Rhododendron japonicum. Kono Kinoshita. *Acta Phytochim.* **5**, 157–65(1930).—Sparassole (I) is obtained from the alc. exts. of roots of *Rhododendron japonicum* collected in November. I is found in the cooled receiver upon distn. of the alc. It m. 67–68°. The yield is 0.36%. Hydrolysis yielded the monomethyl ether of orsellinic acid (II), m. 174–175° from 80% alc. The m. ps. given by previous authors are too low. II is converted to orcine by concd. HCl or HI. A mixed m. p. with a sample of I obtained from another source finally identified the substance as the monomethyl ether of orsellinic acid methyl ester. E. G. F.

The amount of sorbitol in rowan berries. G. Tanret. *Bull. soc. chim. biol.* **12**, 541–3(1930).—The sorbitol (isolated as the dibenzaldehyde deriv.) found on Aug. 15, Sept. 12 and Oct. 15 was 44.4, 66.5 and 68.9 g. per kg. whole berries of *Sorbus aucuparia*, corresponding to 147.8, 209.4 and 173.2 g. total sol. material. Acid and sugar analyses are also given. C. G. King

The penetration of 1-naphthol-2-sulfonic acid indophenol, *o*-chlorophenol indophenol and *o*-cresol indophenol into Valonia. Matilda Moldenhauer Brooks. *Proc. Nat. Acad. Sci.* **17**, No. 1, 1–3(1931).—B. (*C. A.* **23**, 4241) presents the continuation of the studies on oxidation-reduction indicators and their penetration into living plants on *Valonia*. Indicators lying further toward the pos. end of the scale are considered. 1-Naphthol-2-sulfonic acid indophenol does not penetrate into the sap within 24 hrs. at p_H values from 5.8 to 9. *o*-Cresol indophenol and *o*-chlorophenol indophenol penetrate into the sap in a colorless form and faster from an acid than alk. soln. Different equiv. concns. are established accordingly as a phosphate or borate buffer is used. Where reduction has changed the color of the dye, its identity was established spectrophotometrically. B. S. Levine

A source of error in the determination of amide nitrogen in plant extracts. Hubert

B. VICKERY AND GEO. W. PUCHER. *J. Biol. Chem.* 90, 179–88(1931).—HCl is an unsuitable reagent for the hydrolysis of amides in plant exts. and may lead to uncertain results if nitrates are also present, although the so-called Sachsse method in which *N* HCl is used and hydrolysis is continued for 4 hrs. actually gives quite accurate results if these definite conditions of hydrolysis are rigidly maintained. A compensation of errors occurs in which the oxidation of NH_3 by the mixt. of HNO_3 and HCl is counterbalanced by extra NH_3 formed by reduction of HNO_3 under the influence of an easily oxidized unknown substance present in tobacco leaf and other plant exts. Substitution of 2 *N* H_2SO_4 and a 6-hr. hydrolysis are recommended. When this is done accurate and reproducible results are secured with no interference from nitrates and considerable latitude is permissible both in acid concn. and in time of hydrolysis. A. P. L.

Biochemical transformation of acetic acid by molds and the chemistry of citric acid formation. T. CHRZASZCZ AND D. TIUKOW. *Biochem. Z.* 229, 343–57(1930).—In the metabolism of AcOH by the mold *Penicillium* succinic, fumaric, oxalic, *l*-malic and citric acids are formed and probably also other acids not yet identified. The finding of *l*-malic and citric acids is here reported for the first time. It is concluded that the citric acid formation in sugar cultures also proceeds over AcOH. The AcOH is changed to succinic acid and by dehydrogenation, and this in turn is dehydrogenated to fumaric acid. The fumaric acid is changed to *l*-malic acid by taking up a mol. of H_2O. It is assumed that at some moment both malic and acetic acid ions are present in the culture, citric acid being formed from these two by a dehydrogenation The transformation of the sugar to citric acid proceeds over the intermediate stages of pyruvic acid ⟶ acetaldehyde ⟶ AcOH, then as outlined before K and Na ions have a greater effect than Ca ions on the transformation of AcOH, and the formation of citric acid proceeds better; in fact, in the presence of Ca ions alone only succinic and *l*-malic acids have been found S. MORGULIS

Carbohydrate metabolism of higher plants. Formation of methylglyoxal by enzymes of germinating seeds. CARL NEUBERG AND MARIA KOBEL. *Biochem. Z.* 229, 433–42(1930).—Peas or beans were sterilized by submersion for 40 min. in 0.1% $HgCl_2$, then washed thoroughly with sterile H_2O and germinated in Petri dishes After 1–2 days the fresh sprouts were removed from the seed membranes and ground finely, and either extd. or made into dry prepns. with alc.-ether. Exts were made from the latter by 17–20 hrs. digestion with H_2O contg. 3% toluene. The methylglyoxal was produced from added hexose-phosphate ester, whereby the enzyme was completely removed from the fresh material or from the alc.-ether dry prepn., and could not be found in the residue. Obviously methylglyoxal is the intermediate product in the desmolytic changes in the sugar mol. both in plants and animals. S. MORGULIS

Microchemical study of hemicellulose in some plant cells, with special reference to its distribution in the protoplasm. R. C MALHOTRA. *J. Biochem.* (Japan) 12, 341–9 (1930).—Recent studies on hemicellulose seem to suggest that this substance is not merely present in the cell walls impregnated in cellulose, pectin or lignin, but actually is present as a reserve carbohydrate. Microscopic studies reveal that the hemicellulose is present not only in the cell wall but also as protoplasmic inclusions. Hemicellulose tests on tomato cells grown in warm and cold temp. seem to show that there is more hemicellulose in cells of plants grown in the cold than in the warm temp. S. MORGULIS

Glucides and glucidic compounds of the brown algae. H. COLIN AND P. RICARD. *Compt. rend.* 190, 1514–6(1930).—Many algae have been analyzed for mannitol, laminarine and algine. The figures are given. T. H. RIDER

The relationship between intracellular r_H and cytoplasmic sexualization of horsetail spores. PH. JOYET-LAVERGNE. *Compt. rend.* 191, 865–6(1930).—The spores of *Equisetum arvense*, *E. limosum* and *E. maximum* are divided into 2 groups. There is a relationship between the sexualization of the groups and their intracellular oxidation-reduction potentials. T. H. RIDER

The presence of tannoids in flowers. ST. IONESCO. *Compt. rend.* 191, 867–8 (1930).—Flowers or their parts are boiled in 96% alc. or in $(CH_3)_2CO$ until decolorized, then soaked in distd. H_2O until soft again, when the presence of tannoids can be demonstrated by the production of color by treatment with $Fe_2(SO_4)_3$, U acetate, $Cu(OAc)_2$ or K_2CrO_4. All parts of many flowers were found to contain tannoids. T. H. R.

The soluble enzymes secreted by Hymenomycetes. The quinones and the antioxidant function. L. LUTZ. *Compt. rend.* 191, 880–2(1930); cf. *C. A.* 24, 5796.—*Quinone* is shown to have an antioxidant effect, retarding the action of the soln. enzymes of *Hymenomycetes.* T. H. RIDER

Callusing of cotton stem cuttings. H. E. REA. *Plant Physiology* 5, 575–85 (1930); cf. *C. A.* 13, 139.—The treatment of cotton cuttings with 2.0, 1.0, 0.5 and

0.25% of aq. solns. of $KMnO_4$ for 30 min., prior to placing in propagators, reduced the percentage of callusing 37%. WALTER THOMAS

Preliminary study of elongation of roots of Georgia collards as affected by sodium luminal. T. W. PRATT. *Plant Physiology* **5**, 587–97(1930).—Pronounced retardation of root elongation by Georgia collards (*Brassica oleracea*) was produced by sodium luminal, used in concns. from 0.1 to 1.0%, within 1.5 hrs. after administration. The effect of the sodium luminal on the root elongation was immediate, the greatest retardation occurring during the first of the six 15-min. intervals of observation. Distd. water partially removed the depressing action of the sodium luminal. The stronger the concn. of the drug, the greater was the retardation of root growth. WALTER THOMAS

Effect of various methods of storage on the chlorophyll content of leaves. PHILIP A. HARRIMAN. *Plant Physiology* **5**, 599–606(1930).—*Soy bean* and *nasturtium* leaves dried at 98° suffered a considerable loss of chlorophyll (approx. 70%). Leaves dried at room temps. (18° to 24°) lost 20 to 30% of their chlorophyll. Even at the optimum temp. range for oven drying (45° to 60°) some chlorophyll may be lost. Low temps. are ineffective in preventing the loss of chlorophyll unless the leaves are actually frozen. Leaves frozen with "Dry Ice" retain all of their chlorophyll; also leaves desiccated at reduced pressure (7 cm. mercury) over concd. sulfuric acid at room temp. lost little or no chlorophyll. Leaves desiccated at reduced pressure in the absence of O and CO_2 lost more chlorophyll than leaves desiccated in air at the same pressure. *Conclusion.*—Freezing is the most satisfactory method of storing leaves for later detn. of chlorophyll. WALTER THOMAS

Production of kojic acid by Aspergillus flavus. O. F. MAY, A. J. MOYER, P. A WELLS AND H. T. HERRICK. *J. Am. Chem. Soc.* **53**, 774–82(1931).—With 20% dextrose soln., *Aspergillus flavus*, under favorable conditions, is capable of transforming more than 45% of the dextrose present and 55% of that consumed into kojic acid in 12 days from the time of inoculation from spores. $(NH_4)_2SO_4$ was unsatisfactory as nutrient N; NH_4NO_3 was most satisfactory; $NaNO_3$ was much less satisfactory. Better results were obtained with a KH_2PO_4 1 g. and $MgSO_4.7H_2O$ 2 g. per l. than with KCl 0.1, H_3PO_4 0.054 and $MgSO_4.7H_2O$ 0.5 g. per l. A range from 30° to 35° promoted rapid vegetative development with high yields of acid. In a range of sugar concns. from 15 to 35% growth and acid production were satisfactory, the highest yield occurring at a concn. of 20%. The max. quantities of acid were most economically produced in 12-day cultures when the ratio of the surface area of mycelium to the vol. of the soln. had a value of from 0.3 to 0.5. C. J. WEST

Chemical changes in infectious chlorosis in leaves of Abutilon. H. v. EULER, W. HERTZSCH, S. MYRBÄCK, D. RUNEHJELM AND A. FORSSBERG. *Arkiv Kemi Mineral. Geol.* **10B**, No. 13, 6 pp.(1930); cf. *C. A.* **24**, 5332; **25**, 131.—Those portions of the leaves affected with infectious chlorosis have much lower catalase activity, higher proportion of amino N, less chlorophyll, xanthophyll and carotene, and less tryptophan than the normal green portions. J. J. WILLAMAN

Studies on the ripening of rice grains. T. TADOKORO AND M. ABE. *J. Faculty Agr. Hokkaido Imp. Univ.* **27**, 349–87(1930); cf. *C. A.* **22**, 967, 3906.—Rice was harvested at 4 weekly intervals, the last sample being dead ripe. The ash and P decreased at first. The total N showed no definite tendency to change, but the ratio of protein to non-protein N increased constantly. Of the 4 groups of rice proteins detd., the water-sol. group gradually decreased, while the NaCl-sol. and alc.-sol. groups increased. The alkali-sol. group was inconstant in its changes. All of these changes are just the opposite of those during germination. While the non-protein N is decreasing, the amino N of the proteins is also decreasing, indicating a formation of higher proteins from lower. Oryzenin, the alkali-sol. protein, decreased in ash and P during ripening, but increased in N, S and amino N. Its isoelec. point changed toward the alk. side, and its $[\alpha]$ increased. The amt. of amino N liberated from oryzenin by ultra-violet light increased with ripeness. Arginine increased at first and then decreased, while histidine increased continuously. Lysine decreased at the later stage, while cystine decreased and then increased. Thus the authors think that oryzenin is at its highest degree of condensation sometime before dead ripening. The ash and P content of rice starch decreased gradually, while the sapon. value increased. The amt. of glucose formed by hydrolysis with HCl attained a max. before complete ripeness, and at this same period the $[\alpha]$ of the acetylated starch reached a max. and the content of acetyl its min. J. J. W.

A limnological significance of free H_2CO_3 (LINDEMANN) **14.**

E—NUTRITION

PHILIP B. HAWK

Urinary syndrome of metabolic disturbances caused by lack of vitamin B in the rat. J. ROCHE. *Bull. soc. chim. biol.* **12**, 342–56(1930); cf. *C. A.* **23**, 1166.—In rats receiving *ad libitum* the diet of Randoin and Simonnet, the C/N ratio of the urine and feces is practically const. for a normal animal on a given diet, although the actual value varies according to the age of the rat. On a diet deficient in vitamin B the ratio increases (more rapidly as the point of death is approached). Ingestion of yeast temporarily reduces the ratio. The consequences of lack of vitamin B are manifested sooner on a diet rich in carbohydrate. Death is not due to inanition, which would cause a fall in the C/N ratio. B. C. A.

Fractional dialysis of urine. A. BOIVIN. *Compt. rend. soc. biol.* **101**, 722–4(1929).—A vegetable diet increases the quantity of easily dialyzable substances in urine, while a meat, and particularly a milk, diet has the reverse effect. B. C. A.

The effect of irradiated ergosterol (vitamin D) on the calcium-phosphorus metabolism of the chicken. E. J. KING AND G. E. HALL. *Can. Chem. Met.* **15**, 22(1931).—One group of 4-month old chickens was fed an "adequate basal diet contg. all the essential elements for growth except vitamin D." Another received the same diet plus 2 drops of irradiated ergosterol soln. daily. Their growth was normal. Group No. 3 was fed excessive amounts of irradiated ergosterol equiv. to 250–1500 times that given the normal birds. These birds lost wt. rapidly, became strikingly anemic and weak-legged. In the rachitic birds there was an increased phosphatase content of the bones accompanied by a hypocalcemia of the serum and in the hypervitaminous birds a subnormal phosphatase content accompanied by a hypercalcemia. W. H. B.

Effect of acidic and basic diets in chronic nephritis. D. M. LYON, D. M. DUNLOP AND C. P. STEWART. *Edinburgh Med. J.* **38**, 87–108(1931).—High basic, high acid and high purine diets of similar protein content were investigated for their effect in chronic nephritis. The basic diet alone brought about clinical improvement as well as favorable variations in the blood and urine chemistry. RACHEL BROWN

The group of "water-soluble vitamins" and their relationship. III. The scurvy of rats. WERNER KOLLATH. *Arch. exptl. Path. Pharmakol.* **153**, 359–80(1930); cf. *C. A.* **25**, 132.—Rats can be given a disease histologically identical with guinea-pig scurvy by a proper diet. The addn. of alk. hematin to such a diet causes 75% of young rats to develop beriberi; their bones, however, show the same scorbutic changes. It is therefore suggested that the absence of a common factor underlies both beriberi and scurvy, other factors of age, species, or diet detg. which disease will appear. H. E.

Methylglyoxal as an intermediary product of carbohydrate catabolism. ERICH SCHNEIDER AND ERNST WIDMANN. *Klin Wochschr.* **9**, 1916–7(1930).—Previous workers have demonstrated that methylglyoxal is formed by liver, kidneys, muscle cells and red cells in the course of sugar metabolism. By removing the substance (as the 2,4-dinitrophenylhydrazone) S. and W. have shown that it is formed by human red cells, even after hemolysis, and also by white blood cells. As much as 70–75% of the total glucose added passes through the methylglyoxal stage. Diabetic blood cells show no abnormality in this respect. Material from abscesses did not form the substance, even though the bacteria involved were quite active, either in pure culture or when added to fresh leucocytes. H. EAGLE

Biological significance of milk peroxidase: Preliminary report concerning a relation between vitamin B and peroxidase. TAYURU ARAKAWA. *Tohoku J. Exptl. Med.* **16**, 118–22(1930).—Pregnant rabbits on a diet contg. no vitamin B secrete milk contg. no peroxidase. With the addn. of vitamin B (beriberol) to the diet, peroxidase appears in the milk. H. EAGLE

"Aperoxidatic" milk as a possibly early symptom of avitaminosis B. An experimental study. KAZUŔ SUZUKI AND TAYURU ARAKAWA. *Tohoku J. Exptl. Med.* **16**, 228–31(1930).—In rabbits secreting peroxidase-free milk on a diet contg. no vitamin B, the peroxidase reaction of the blood leucocytes remains as strong as normal. H. E.

Studies on the quantity of the glomerular filtrate. I. Glomerular filtrate in beriberi. FUSAKICHI NAKAZAWA AND HYOE KUSAKARI. *Tohoku J. Exptl. Med.* **16**, 321–8 (1930).—The glomerular filtrate of normal humans is 200–150 cc. per min., as estd. by creatinine output (if it is assumed to be a simple filtrate, with neither tubular secretion nor resorption). In beriberi it is much lower, and may fall to as little as 10 cc. per min. With the administration of vitamin B, this returns to its normal value. H. EAGLE

The toxicology of the irradiated products of ergosterol. WOLFGANG HEUBNER.

Nachr. Ges. Wiss. Göttingen Math.-physik. Klasse No. 2, 149–63(1930).—The irradiated products of ergosterol were prepd. according to the method of Windaus, some of the samples being irradiated in ether, some in benzene and others in alc. In most cases the light from Mg was employed. Expts. on rabbits which were fed with the ergosterol products showed various pathological effects centered chiefly in the aorta and arteries. Death, following a loss in wt., occurred in all cases. Calcification foci were found in the aorta upon postmortem exam'n. Data are presented in 13 tables. RUSSELL C. ERB

The feeding of milk goats with a ration consisting of oat straw and nutritive material but poor in vitamin A, and its supplement. A. SCHEUNERT AND K. BERTRAM. *Tierernähr.* 1, No. 1, 70–87(1929).—During a 400-day expt. 3 milk goats were fed on a ration of oat straw, dried scraps and nutritive matter, but lacking in hay or green food. To insure milk production it was necessary to add a salt mixt. of CaO, H_3PO_4 and NaCl. Before the addn. of this mixt. the milk yield dropped but rose to normal again upon the addn. Adding wheat germ, which contains a small amt. of vitamin A, produced a temporary increase in the milk yield. The effects of a lack of vitamin A were evident in 2 of the animals. One of these did not become pregnant and the other gave premature birth to 2 dead kids. The one goat that was given vitamin A daily in the form of 10 cc. of cod-liver oil went through an apparently normal pregnancy and gave birth to two dead kids and one living kid. The latter showed good development. After 3 months on the vitamin-A deficient diet, the milk showed a deficiency in vitamin A. A long time was required to bring the milk vitamin content back to normal. RUSSELL C. ERB

Nutritional study of the white school children in five representative counties of Florida. CHESTER F. AHMANN, OUIDA D. ABBOTT AND GEORGIA WESTOVER. Fla. Agr. Expt. Sta., *Bull.* 216, 5–50(1930).—A survey of defects in white school children as correlated with diet, wt., age, etc. C. R. FELLERS

Effect of the use of mineral oil upon the absorption of vitamin A. JENNIE I. ROWNTREE. *J. Nutrition* 3, 345–51(1931).—The effect of mineral oil on the absorption of vitamin A is dependent on the amt. of vitamin A in the diet. When the quantity of mineral oil given to rats is comparable to the human therapeutic dose and the vitamin A only enough to produce subnormal growth, the rats are unable to withstand the effects of the mineral oil. However, if the amt. of vitamin A is adequate, mineral oil can be given without noticeable effects. If sufficient vitamin is given the amt. of mineral oil could be increased 50% without producing a slackening of growth or preventing the cure of severe ophthalmia. If this laxative is employed, it should be accompanied by a generous amt. of fat-sol. vitamins. Bibliography. C. R. FELLERS

Preparation of a concentrated source of the heat-labile vitamin B, free from contamination with the heat-soluble factor G. HERBERT M. EVANS AND SAMUEL LEPKOVSKY. *J. Nutrition* 3, 353–74(1931).—25% EtOH is an efficient extractive of both the heat-labile and heat-stable, water-sol. vitamins; the heat-stable factor is in low concn. in the outer layers of the rice kernel and decreases further in abundance in the inner layers, whereas the heat-labile factor is in high concn. in the rice outer layers and decreases only slightly in the inner layers. Clay activated by the 25% ext. furnishes an excellent source of vitamin B free from the heat-stable factor. When the sirup resulting from concn. of a 25% ext. is treated with 95% alc. so that the resulting concn is 90%, most of the heat-stable factor is removed; nevertheless, large losses in the heat-labile factor are produced in this way. When the final concn. is 80% these losses are much reduced, though somewhat more heat-stable vitamin is present. In the case of the rice polish, so little of the heat-stable factor is initially present that fractionation with the 80% alc. yields an ext. almost free of the heat-stable factor and very rich in vitamin B. Finally, adsorption with clay is more selective for the heat-labile vitamin and thus the last traces of the heat-stable factor are left behind. Quant. removal of antineuritic B from clays by means of $Ba(OH)_2$ was not achieved, though feeding of these clays gave a high dosage of antineuritic B with assured absence of the heat-stable factor. Bibliography. C. R. FELLERS

Factors which determine renal weight. VII. Protein intake and age. EATON M. MACKAY AND LOIS LOCKARD MACKAY. *J. Nutrition* 3, 375–85(1931); cf. *C. A.* 23, 2744.—An extended study of the linear relationship between renal wt. and protein intake proved that it is not influenced by age. The empirical linear formula, *protein intake* = 0.0183 *renal wt.* − 2.75, expressed the relationship in normal male rats 70, 130, 220 and 400 days old when receiving adequate amts. of protein in the form of casein. **VIII. Protein intake and sex.** *Ibid* 387–94.—A linear relationship between renal wt. and protein intake was demonstrated for female rats at all ages. When receiving adequate amts. of protein in the form of casein it may be expressed: *protein intake* =

0.0183 *renal weight* − 2.2875. This is similar to the formula expressing the same relationship for male rats, except that at a zero protein intake it demands a theoretical renal wt. in relation to a unit of body surface (100 sq. cm.) of 125, instead of 150 mg.
C. R. FELLERS

Further experimental differentiation of vitamins B and G. H. C. SHERMAN AND M. R. SANDELS. *J. Nutrition* 3, 395–409(1931); cf. *C. A.* 23, 1160.—Dried bakers' yeast yielded a much larger proportion of its vitamin B (B_1) than of its vitamin G (B_2) to extn. with 80% EtOH. In 95% EtOH, no measurable amt. of the vitamin G of yeast was dissolved; in 80% EtOH the soly. was appreciable; in 60% EtOH the vitamin G was more sol. The soly. of vitamin G increases as the proportion of H_2O in the EtOH:H_2O solvent is increased. It was found best to judge the soly. of the vitamin from the feeding of the residue rather than of the ext. for a part of the extd. vitamin G disappeared and it is suggested that this may have been due to a partial destruction of vitamin G by oxidation. There was no corresponding loss of the extd. vitamin B. Rats lacking vitamin B showed a much more rapid decline of food consumption than those lacking vitamin G. It is evident that vitamin B (B_1) has a relation to the maintenance of appetite and the prevention of polyneuritis in rats; that growth in the rat requires both vitamins B and G and responds, within limits, according to the level of feeding of each; and that lack of vitamin G, under sufficiently controlled conditions, quite regularly produces in the rat the deficiency disease designated as pellagra-like by Goldberger and his associates and by Chick and Roscoe, though the particular type of skin lesion which this term suggests is not characteristic of the cases of most complete deprivation of vitamin G. Whether the observed variability of symptoms of the G-avitaminosis is connected with multiple nature of vitamin G is a question still under investigation. Bibliography.
C. R. FELLERS

Influence of bulk in the diet upon fecal calcium and phosphorus. LEAH ASCHAM. *J. Nutrition* 3, 411–20(1931).—Five dogs were kept in a neg. Ca balance at all times to better to interpret the results. The food unit consisted of a food mixt. contg. const. mixed amts of casein, sugar, lard and salt mixt. but of varying proportions of cellulose-flour and agar. The only diet changes made were in the kind and amt. of roughage. With but 1 exception excretions of both Ca and P were greatest during the periods of high roughage, the agar causing the higher excretions. If Ca has a physiol. action of importance in the intestines, the data do not show it, and it is impossible to assign a special function to Ca.
C. R. FELLERS

Autoxidation of fats with reference to their destructive effect on vitamin E. MARIAN J. CUMMINGS AND H. A. MATTILL. *J. Nutrition* 3, 421–32(1931).—Observations on the susceptibility to oxidation of several fats and oils were correlated with the reproductive behavior of rats reared on food mixts. contg. these same fats. The autoxidizability of the fats was measured by the induction period of O absorption and the length of this period increased in the following order: cod-liver oil, lard, butter fat, cottonseed oil, stearin, hydrogenated cottonseed oil. When mixed as in the diets, the fats mutually influenced the autoxidizability of the mixt. The reproductive behavior of animals, as indicated by the nos. of litters, the frequency of resorptions and the wts. of the testes, indicated that the mixt. of hydrogenated cottonseed oil and butter was most satisfactory, that of lard and cod-liver oil and that of stearin and butter were least successful. Intermediate were the mixts. of cottonseed oil with butter and with cod-liver oil, and the combination of hydrogenated cottonseed oil with cod-liver oil. The animal tests are in general agreement with the chem. tests and indicate that the knowledge of the distribution of vitamin E is relative rather than absolute. The efficiency of a given source of vitamin E depends, in part, upon the autoxidizable materials and antioxidants which are assocd. with it. The possible role of vitamin E as an antioxidant is discussed. Full bibliography.

Role of diet in the cause, prevention and cure of dental diseases. MILTON T. HANKE. *J. Nutrition* 3, 433–51(1931).—An extraordinarily complete editorial review with bibliography.
C. R. FELLERS

Antianemic potency of cane and beet molasses. W. E. KRAUSS. Ohio Agr. Expt. Sta., *Bimonthly Bull.* 147, 182–3(1930).—Rats fed upon an exclusive milk diet develop nutritional anemia and die as a result of a lack of Cu and Fe. Cane and beet molasses were fed rats as milk supplements. Both were also fed to anemic rats to test their curative properties. Cane molasses possessed excellent anemia-preventing and anemia-curative properties while beet molasses was very much inferior. A chem. examn. of the ash of cane and beet molasses showed the former to contain appreciable quantities of Cu and Fe while beet molasses ash was very deficient.
C. R. FELLERS

Lime in animal production. D. W. MAY. *Porto Rico Agr. Expt. Sta.* 1929. *Repl.*

4–5(1930).—Osteoporosis, a disease of horses where the bones, especially of the head, become porous and soft, was caused by diets deficient in Ca. The heavy clay soils of Central Porto Rico are definitely deficient in lime and the crops raised thereon are similarly deficient, thus giving rise to the disease in animals when the crops are used for fodder. The addn. of sea salt, bone meal and lime to the ration is recommended. C. R. FELLERS

Nutritional discoveries in relation to livestock feeding practices. G. BOHSTEDT. *Sci. Agr.* **11**, 65–73(1930).—General. C. R. FELLERS

Mineral feed problem with dairy cattle and swine. G. BOHSTEDT. *Sci. Agr.* **11**, 74–7(1930).—Tabular data are presented showing the most common mineral deficiency diseases in livestock and the remedy. C. R. FELLERS

Antiscorbutic power of fruit and flour. T. SCHLOSSBERG. *Compt. rend. soc. biol.* **102**, 1104(1930); *Physiol. Abstracts* **15**, 101.—Orange juice and lemon juice prevented the onset of scurvy in guinea pigs on a diet which otherwise caused it. Powd. milk and yeast added to flour had no preventive action. G. G.

Value of fats in the feed of dairy cows. ARNOLD BUSCHMANN. *Tierernähr.* **1**, 129–78(1930).—The effect of adding vegetable oils or oil-rich seed meals to the ration of dairy cows was studied. Up to a certain limit, varying from 0.4 to 1.0 kg. oil per day per 1000 kg. body wt., the fat content of the milk was not changed or was increased less than 0.1%. Feeding larger amts. slightly decreased the milk fat. The limit was lowest for rapeseed oil, highest for coconut, with sesame and linseed intermediate. The chem. and phys. constants of the milk fat were altered to the same extent as though approx. 18% of the particular oil in question had gone directly into the milk as so much butter fat. L. E. GILSON

Vitamin D efficacy of hog feeds. VALENTIN HORN. *Tierernähr.* **1**, 194–205 (1930).—Healthy hogs made greater gains in wt. in proportion to the amt. of food eaten when "Hemon," a com. irradiated phytosterol prepn., was added to the ration, but not sufficient to show a profit over the addnl. expense. L. E. GILSON

Does the addition of potassium iodide to the diet affect the composition of the intestinal and fecal flora? A. SCHEUNERT AND J. RODENKIRCHEN. *Tierernähr.* **1**, 206–18 (1930).—This question has been raised by the widespread adoption of table salt contg KI. Rats were given 0.20 mg. KI per day in their ration and compared with rats not given KI. There was no apparent difference in the counts of the various bacteria and fungi. Tables of bacterial counts are given. L. E. GILSON

Vitamin D preparations in hog feeds. VALENTIN HORN. *Tierernähr.* **1**, 295–305 (1930); cf. preceding abstr.—Vigantol-Merck and Hemon when fed in equiv. quantities were equally efficaceous in restoring to health and promoting the growth of groups of sick, coughing, rachitic young pigs. L. E. GILSON

Tryptophan and histidine as "anabolites." GEORGES FONTÈS AND LUCIEN THIVOLLE. *Compt. rend.* **192**, 63–5(1931); cf. *C. A.* **25**, 1575.—Simultaneous injection of tryptophan and histidine allows a living organism (dog) in equil. with an unchanging diet, to make very clear gains in wt., which are attained rapidly and maintained for a long time. These gains may be explained only by an improvement in the general assimilation processes, and especially those which have to do with N metabolism. The name "anabolite," as proposed for these amino acids, seems justified. L. K.

Metabolism of lipides. The role of the pancreas endocrine in the phenomena of pulmonary fat catabolism. I. I. NITZESCU AND GR. BENETATO. *Bull. soc. chim. biol.* **12**, 827–48, 849–72(1930); cf. *C. A.* **24**, 5811.—From the content and rate of catabolism of fats in lung tissue and blood, *in vivo* and *in vitro*, N. and B. conclude that the destruction of fats in the tissues is dependent on a localized thermolabile factor which is activated by insulin which functions as a coenzyme or kinase. The localized factor is also diastatic, controlling the catabolism of glycogen. C. G. KING

Resistance of chickens to parasitism affected by vitamin A. JAMES E. ACKERT, MARIAN FISHER MCILVAINE AND NAOMI ZIMMERMAN CRAWFORD. *Am. J. Hyg.* **13**, 320–36(1931).—The resistance of growing chickens to the intestinal round worm, *Ascaridia lineata*, was lowered when the fowls, 4–7 weeks of age, were kept on a diet deficient in vitamin A for a period of 5 weeks. The larger no. of worms remaining in the chickens is attributed to a weakened peristalsis. The source of the vitamin A in the control animals was cod-liver oil. The criteria for judging whether this vitamin affected the resistance of the chickens to the parasites were the no. and the lengths of the worms remaining in the chickens at the close of the expt. N. A. LANGE

Resistance of chicken to parasitism affected by vitamin B. JAMES E. ACKERT AND L. O. NOLF. *Am. J. Hyg.* **13**, 337–44(1931).—Preliminary tests were carried out to ascertain if the vitamin B complex is a factor in the resistance of chickens to the in-

testinal round worm, *Ascaridia lineata*. The source of vitamin B was baker's yeast. Groups of chickens given the same no. of embryonated eggs of the parasite had more worms when their diets lacked vitamin B than did similar groups fed adequate amts. of this vitamin. The larger no. of worms is attributed in part to partial paralysis of the intestine due to lack of vitamin, the greatly weakened peristalsis probably aiding the worms in remaining in their habitat. It is suggested that yeast may contain a factor which is favorable to the growth of worms since larger worms were found in those chickens whose diet contained yeast. N. A. LANGE

Variations in the chlorine content of the blood serum and urine of mice subjected to acute experimental scurvy. LUCIE RANDOIN AND ANDRÈE MICHAUX. *Compt. rend.* 191, 1378–80(1930); cf. *C. A.* 24, 4535. B. S. LEVINE

The effect of fluorine on the calcium metabolism of albino rats and the composition of the bones. F. J. MCCLURE AND H. H. MITCHELL. *J. Biol. Chem.* 90, 297–320 (1931).—Fluorine, especially when consumed in the more sol. form of NaF at levels of 0.0313 and 0.0623% of F, may cause the deposition of an apparently abnormal constituent in the bones or an abnormal deposition of a non-Ca constituent, possibly a fluoride of a mineral other than Ca, as evidenced by an increase (av. 1.3%) in the % of ash in the bones above the normal. There is also an interference with the deposition of Ca in the bones (av. decrease in Ca content 1.05%). The P content of the bone ash was not significantly affected by NaF feeding but the Ca:P ratio was depressed. When either CaF_2 or NaF was fed at the above levels, growth was inhibited entirely aside from any effect on food consumption; the higher level of NaF only lowered the food consumption also. The Ca balance was unaffected by either CaF_2 or NaF up to the level of 0.0313% F in the ration but at a level of 0.0623% the % of Ca that would otherwise have been retained by the exptl. rats was lowered. The peculiar effect of F on the development of the teeth was again demonstrated; the characteristic abnormalities appeared when either the sol. NaF or the insol. CaF_2 was fed. Bibliography of 37 references. A. P. LOTHROP

The physiological effects of diets rich in egg white. HELEN T. PARSONS. *J. Biol. Chem.* 90, 351–67(1931); cf. *C. A.* 24, 5802.—Diets rich in egg white speedily cause a nutritional disorder and death in young rats weaned from stock rations. As little as 5% of dried liver fed for 3 days before the beginning of the egg diet protects the rats from this disorder. The swiftness of onset of the first acute symptoms suggests that the effect is due to a direct injury from the egg white rather than to a nutritional deficiency in the usual sense of the term. In rats surviving the 1st few weeks on a ration contg. 66% of dried egg white, either raw Chinese, or from raw fresh eggs, symptoms developed which strikingly resemble pellagra even though the ration contained 20% of potent dried yeast. These symptoms were prevented or cured by 20% of dried beef liver (but not by 10%) no matter how far advanced the dermal or nerve involvement. Lard and raw linseed oil were ineffective as preventive or curative agents. The symptoms noted were loss of wt., lessened activity, an awkward gait in walking, a humped back, meteorism, increased shedding of hair, soiled fur, paws and tail, closed eyelids, bloody urine, and progressive spasticity. The results suggest caution in the use of as large quantities of egg white in invalid feeding as has been the common practice in many hospitals. The introduction of egg white into the somewhat restricted dietary of a child may also perhaps need to be safeguarded with protective foods in somewhat the same way as its introduction into the diets of the rats used in the expts. A. P. L.

Ketogenesis in relation to the food of swine. V. ZAGAMI. *Arch. intern. physiol.* 33, 159–72(1930).—Swine excrete considerable amts. of "ketone bodies" when fed carbohydrate diets. These are increased considerably upon fat or protein diets. Fats produce a greater increase than proteins. The NH_3 excretion does not parallel that of the ketones but bears a relation to the protein ingested as well as to the "ketone bodies" excreted. In this phase of intermediary metabolism swine contrast with the herbivora. C. M. MCCAY

The metabolism of nitrogen. VII. Comparative influence of carbohydrates and fats upon the utilization of nitrogen. G. PASQUALINO. *Arch. intern. physiol.* 33, 185–95(1930).—A series of diets was designed contg. casein, egg albumin and glutin. These proteins were fed with either starch or butter. The N balances were detd. P. supports his earlier thesis that 10–40% of the N intake cannot be accounted for by fecal N plus urine N plus body weight increase. He finds no influence of fats or carbohydrates upon the "lost" N. C. M. MCCAY

Experimental studies on the influence of diet on the formation of biliary and renacalculi. II. Feeding on a diet deficient in fat-soluble vitamins. 2. The quantitative change in potassium, sodium, calcium, magnesium, total cholesterols and total

fatty acids in the blood. KAZUMASA USUNI. *Japan J. Gastroenterology.* **2,** 226–30 (1930).—Normal values upon the sera of 82 young rabbits (50–120 days) were established as follows:

	Range (mg. %)	Mean (mg. %)
Ca	26.25— 17.56	22.37
K	17.56— 8.23	13.36
Mg	3.76— 2.40	3.24
Na	605.00 - 360.00	492.00
Total cholesterol	80.35— 47.56	60.5
Total fatty acids	254.12 -160.00	19.0

These same constituents were detd. upon 72 normal rabbits after they were placed upon a diet deficient in vitamin A. In cases that developed eye symptoms there was a marked increase in serum Ca. All the blood constituents increased in cases of calculi formation independently of the appearance of symptoms of avitaminosis. Ca and cholesterol increased the most. C. M. MCCAY

Vitamins. Physicochemical constants of serum and plasma of animals fed on autoclaved meat with or without yeast. FERDINANDO NEGRI. *Biochim. terap. sper.* **17,** 445–60(1930).—Dogs, fed exclusively on autoclaved meat, do not live longer than 2 months. The body temp. decreases especially in the last week of life. The p_H and the alkali reserve decrease; the refractive index of the serum decreases constantly. The sugar and N in the blood decrease; the latter increases in the urine; creatine in the blood and creatinine in the urine increase considerably. The addn. of yeast restores the animal almost to normal; only an innocent hyperglucemia was observed. A. E. M.

Changes in the central nervous system in some avitaminoses. SILVIO BRAMBILLA *Sperimentale* **84,** 537–52(1930).—Histological investigations of the central nervous system in scurvy of guinea pigs and in rickets of rats showed only slight degenerative changes, higher in scurvy than in rickets. No reason was found to suppose a unity of the neuropathol. picture in different avitaminoses. A. E. MEYER

Sauerkraut as a source of vitamin C. B. A. LAVROV AND NATALIE YARUSOVA *Biochem. Z.* **220,** 115–27(1930).—Hay and oats which have been autoclaved invariably produce typical scurvy in guinea pigs receiving this as their basic diet. Addn of sauerkraut to such a basic diet inhibits the development of the disease process, 30 cc. of the juice being required for a prophylactic dose. If it is assumed that the amt. of vitamin C present in the min. prophylactic dose of a definite product is a vitamin unit, 1 kg. sauerkraut juice contains only 33 units, 1 kg. sauerkraut 26 units while apple juice (cider) will contain 330 to 660 units per kg. S. MORGULIS

Hypervitaminosis in chickens. EARL J. KING AND G. EDWARD HALL. *Biochem. Z.* **229,** 315–22(1930).—Under the influence of overdosage with radiated ergosterol no calcareous deposits were observed in the organs of chickens; nevertheless the bones were weak and bent. There was a decreased phosphatase content in the bones and in the kidney. S. MORGULIS

Studies in experimental scurvy. X. Adrenaline content of the suprarenals and the amount of the adrenaline-like substance in the serum of guinea pigs fed on a vitamin-C-free diet. SHINSUKE OHATA. *J. Biochem.* (Japan) **12,** 419–27(1930). In the serum of scorbutic guinea pigs there is a definite diminution in the amt. of adrenaline-like substance as well as a decrease in the adrenaline content of the suprarenal glands. Although the adrenaline content of the gland decreases also during inanition, this decrease is not as great as during scurvy. The change in the adrenaline like substance of the serum is the same in inanition and scurvy. The effect on a vitamin-C free diet is, therefore, not purely an inanition effect. S. MORGULIS

The relation of carotene to vitamin A. BASHIR AHMAD. *J. Soc. Chem. Ind.* 50, 12–4T(1931); cf. *C. A.* **23,** 1941; **24,** 402, 5801. Colored palm oils from different sources were tested colorimetrically for carotene and biologically for vitamin A. Tests were also made upon oils in which the carotene had been partly or largely destroyed by hydrogenation. The results of these tests indicate that the yellow coloring matter in the vegetable oils is carotene and that this substance shows vitamin A activity. Certain charcoals adsorb carotene, during which process it is oxidized and so made biologically inactive. In fish-liver oils, the pigment can be adsorbed without destruction of vitamin A. N. M. NAYLOR

Lung calcification in healthy and tuberculous rabbits caused by massive doses of irradiated ergosterol. H. SIMONNET AND G. TANRET. *Compt. rend.* **190,** 1520–9 (1930); cf. *C. A.* **24,** 2409.—Irradiated ergosterol increases pulmonary calcification in

normal rabbits in a ratio of 1:20, while in tuberculous rabbits, the increase was as high as 1:80. In chronic tuberculosis the evolution of tubercules is checked. T. H. R.

Biochemical investigations on rubrene. M. JAVILLIER AND (MLLE.) L. EMERIQUE. *Compt. rend.* **191**, 882–4(1930).—*Rubrene* (I), $C_{42}H_{28}$, is a cryst., orange-red compd. rich in double bonds, and is decolorized by fixation of O_2. It is in many ways analogous to *carotene* (II), $C_{40}H_{56}$. Albino rats fed on a diet deficient in vitamin A were fed I without improvement in the vitamin-A-deficiency symptoms. 75% of I by mouth is eliminated in the feces. The remainder is probably altered in the body since I cannot be detected in the organs. I and II are therefore not physiologically similar.
T. H. RIDER

Further observations on the toxic effects of irradiated ergosterol. J. C. HOYLE. *J. Pharmacol.* **40**, 351-72(1930); cf. *C. A.* **25**, 134.—Bread or milk added to a synthetic diet did not protect rats against the toxic action of alc. irradiated ergosterol which contained a high concn. of vitamin D. A diet modified to contain protein, carbohydrate, fat and ash in the proportions found in a bread-and-milk diet conferred no protection. A diet contg. a smaller proportion of Ca and P had no protective action against irradiated ergosterol with either high or low concn. of vitamin D. A bread-and-milk diet had no protective action against amts. of irradiated ergosterol contg more than 70,000 antirachitic units.
R. RIEGEL

Further biochemical studies on the antineuritic vitamin. ATHERTON SEIDELL AND MAURICE I. SMITH. *U. S. Pub. Health Repts.* **45**, 3194–3200(1930).—The potency of a vitamin salt mixt. prepd. from brewer's yeast by the methods described by Smith (*C. A.* **24**, 1408–9) and Seidell (*C. A.* **23**, 4723) was compared with that of a sample of the crystals prepd. by Jansen (*C. A.* **21**, 2150). 0.05 mg S. and S. prepn. contg. 0.0062 mg. N_2 has the same curative value as 0.04 mg. J.'s crystals contg. 0.0069 mg. N_2. There is not sufficient evidence to conclude that the same compd. is involved in both prepns. S. and S. purified their prepn. by J.'s method, but no crystals were obtained. Rats were placed on a diet deficient in the antineuritic vitamin, until polyneuritis developed. The ration was then changed to one deficient in both vitamins, and the antineuritic concentrate administered intravenously (0.1 mg. per day). The rats recovered from paralysis but failed to grow. Death, due to nutritive failure, followed in 22–32 days.
W. GORDON ROSE

Catalytic vitaminic substances and their action in beriberi. ALESSANDRO SEPILLI. *Zymologica, Zym., Chim. Col. e Zucch.* **5**, 13–7(1930).—The expts. prove that besides having a strong action against putrefactive bacteria lactic ferments also cure polyneuritis in pigeons.
R. SANSONE

Further fractionation of yeast nutrilites and their relationship to vitamin B and Wildiers' "bios." ROGER J. WILLIAMS AND ELIZABETH M. BRADWAY. *J. Am. Chem. Soc.* **53**, 783–9(1931).—Expts. with Wildiers' original yeast culture show that his "bios" is not readily adsorbed by fuller's earth and appears to be the same as the nutrilite which stimulates the growth of Gebrüde Mayer yeast. No conclusive evidence of its multiple nature is available. The yeast nutrilites studied by Miller and his associates are shown to be distinct from the "bios" of Wildiers. The Toronto workers should be credited with the discovery of a new series of yeast nutrilites. Yeast No. 578 of the Am. Type Culture Collection and old process baker's yeast appear to have more complex requirements than Wildiers' yeast. Evidence is presented for the existence of a fourth distinct nutrilite concerned in the growth stimulation of yeast No. 578. It seems reasonable to suspect that several of the nutrilites for this yeast may be components of "vitamin B," since the antineuritic vitamin has previously been shown to affect its growth very strikingly.
C. J. WEST

Optical activity of cystine preparations used for animal experimentation. J. R. HAAG. *J. Am Chem. Soc.* **53**, 808–9(1931). Marston and Robertson (*C. A.* **23**, 4970) have criticized studies of the use of cystine because the optical activity of the prepns. was not detd. Of 7 prepns. examined, the value for α_D^{31} varied from —207.4° to —216.6°; one had the value —185.9°. This variation cannot be explained on the basis of S content but is partly due to the prolonged washing of certain samples with hot H_2O in order to remove the tyrosine present. It is highly probable that any one of the 7 samples is suitable for animal feeding unless it is assumed that inactive cystine is highly toxic.

Irradiation products from ergosterol. SOC. DES USINES CHIMIQUES RHÔNE-POULENC. Brit. 335,277, June 25, 1929. In order to obtain substances having intense antirachitic effect, unconverted ergosterol is sepd. from the product obtained by the irradiation of ergosterol, by crystg. from org. solvents in which the ergosterol is slightly sol. such as alc., acetone and EtOAc (the sepn. being continued until the sol. residue in alc. soln. shows a dextro-rotatory power greater than 25° for the yellow line of Hg). The active product may be obtained by distn. of the solvent or may be taken up in a vegetable oil. The irradiation may be effected in EtOH at a temp. of 75° while agitating the soln. with an inert gas, preferably with light having few or no rays below 2750 A. U. and is preferably stopped somewhat before the max. production of antirachitic vitamin is reached.

E. K. MARSHALL, JR.

Skin. III. Sugar content of the skin under physiological and pathological conditions. E. URBACH AND G. SICHER. *Arch. Dermatol Syphiles* **157**, 160-82(1929); cf. *C. A.* **23**, 174, 893.—Values of the sugar content of the skin and blood, resp., are: man 47, 98; rabbit 117, 109; guinea pig 119, 117; rat 80, 83; dog 60, 92; mouse 53, 108 mg. per 100 g. (cc.). After administration of sugar the skin sugar increases like the blood sugar and returns to normal values. The skin sugar is diminished by insulin The effect of pathol. conditions of the skin is described. B. C. A.

Water and phosphorus compounds of the nerve on degeneration. R. M. MAY. *Compt. rend.* **190**, 1150-1(1930).—During the first month the water content of the degenerated sciatic nerve of the rabbit increases to 14% above the normal and thereafter falls to the normal value. The total P diminishes progressively during the first 2 months to a third of its normal value. The lipin P decreases after 100 days to a tenth of its normal value, when histological examn. shows complete reabsorption of the lipin products of the nerve. The alc.-sol. and the protein P after an initial rise diminish to a third of the initial values, while the water-sol. P shows a steady increase up to 35% above the normal value after 6 months. Also in *Bull. soc. chim. biol.* **12**, 934-53(1930). B. C. A.

Urea and ammonia in normal gastric juice. D. SIMICI, R. VLADESCO AND M POPESCO. *Compt. rend. soc. biol.* **101**, 199-202, 202-4(1929).—The gastric juice of fasting persons contains 0.014-0.042% of urea and 0.0048-0.0098% of NH_3, the values being scarcely affected by a test meal. Injection of urea (5-10 g. in 20 cc. of water) raised the values to 0.06 and at least 0.03%, resp. In pathol. conditions not affecting the kidneys these values are not markedly changed; in those affecting the kidneys they are increased to 0.3 and 0.11%, resp. B. C. A.

Dextrose in normal urine. H. ROTH. *Compt. rend. soc. biol.* **101**, 218-20(1929). The amt. of dextrose in normal urine varies between 0.02 and 0.30%, depending on the time of day. After fermentation with yeast there remains in the urine 0.01-0.02% of reducing non-sugar substances. B. C. A.

Non-dialyzable fraction of urine. A. BOIVIN. *Compt. rend. soc. biol.* **101**, 724-6 (1929).—The wt., C-N ratio, S content and P content of the non-dialyzable fraction of human urine depend on the technic of the dialysis. B. C. A.

Oxygen consumption of the heart in varying, approximately isotonic, work. L BAUER. *Z. Biol.* **89**, 513-22(1930).—By the method of Eismayer and Quincke (*C. A.* **23**, 2504), it is shown that the amt. of O used for each contraction of the heart does not increase proportionately with increase in pressure, and therefore in work done, but bears a linear relationship to the initial vol. before contraction. B. C. A.

The equilibrium between glycogen and lactic acid. WILDER D. BANCROFT AND GEORGE BANCROFT. *J. Phys. Chem.* **35**, 195-214(1931).—The rate of formation of

lactic acid during fatigue and the quantity of lactic acid found in fatigued muscle can be explained by assuming that enzymes catalyze its formation from glycogen. The reaction is revers ble, but glycogen may be stabilized by adsorption on protein. The formation of acid would be slow during anaerobic rest for this reason. The rapid action as a result of heat rigor or administering $CHCl_3$ is due to liberation of glycogen from the protein. Narcotics might act by freeing adsorbed glycogen from protein or by freeing enzymes from adsorption on the lipins or by a combination of the 2 reactions. The lactic acid found in the muscle is dextrorotary. One would expect inactive lactic acid to be formed by ordinary chem. processes. The adsorption of glycogen on protein could account for the conversion of lactic acid to glycogen during recovery of a muscle. Some failures to find glycogen adsorbed on protein or as a result of the action of enzymes on lactic acid are due to faulty methods of analysis. The *formation of lactic acid from glycogen in cancer* follows a path different from that followed in normal tissue. F. E. BROWN

Recent advances in the physiology of digestion. IV. The intestine. H. H. DUKES. *J. Am. Vet. Med. Assoc.* **31**, 235-9(1931); cf. *C. A.* **25**, 993.—A review. RACHEL BROWN

Studies in blood diastase. Factors which cause variation in the amount of diastase in the blood. CHARLES REID AND B. NARAYANA. *Quart. J. Exptl. Physiol.* **20**, 305–11 (1931).—The diastase in the blood was detd. by the method of Fyfe. Observations were made chiefly on dogs but also on humans, rabbits and cats. The blood diastase decreased after meals, injections of glucose, glycogen and insulin, but increased after anesthetics and injections of starch. Since pancreatectomy and ligature of the pancreatic duct caused little or no change in the amt. of circulating diastase, the pancreas is not the main source of blood diastase. Since definite variations can be induced by injections of insulin and glycogen, it appears likely that the circulating diastase is not entirely a waste product on its way to excretion. Evidence is adduced that variations in blood diastase are probably due to its being taken up or given out by the liver cells accord ng to the requirements of the body with respect to the glycogen-glucose equil. probably in assocn. with insulin. RACHEL BROWN

Placental hormones. J. B. COLLIP. *Can. Med. Assoc. J.* **23**, 631-3(1930); cf. *C. A.* **24**, 5812.—A brief résumé of work already reported, in which C. stresses his view that the human placenta contains at least 3 distinct active principles, one a sp. product of placental tissue functioning, and actively related to the condition of pregnancy. A. T. CAMERON

Notes on the clinical use of certain placental extracts. A. D. CAMPBELL AND J. B. COLLIP. *Can. Med. Assoc. J.* **23**, 633-6(1930); cf. *C. A.* **24**, 2781.—Observations on 135 cases of deranged ovarian function led to the following conclusions: Emmenin does not alter normal menstrual cycles. Its effect in dysmenorrhea has been particularly encouraging, and it appears to correct certain types of amenorrhea of recent origin. It definitely lengthens the cycles in polymenorrhea. It relieves the menopausal symptoms of recent origin, but not in castrates. An anterior-pituitary-like principle from the placenta arrests certain forms of metrorrhagia. A. T. CAMERON

The basal metabolism during harvesting. G. FARKAS, J. GELDRICH AND A. SZAKÁLL. *Arbeitsphysiol.* **3**, 468-76(1930); cf. *C. A.* **23**, 887; **24**, 5352.—The basal metabolism of 6 harvesters was detd. by the Douglas bag method during varying lengths of time, the longest for a period of over 7 weeks. The basal metabolism at the time of the most strenuous work varied from 1.20 to 1.36 cals. per kg. per hr. and was about 10% higher than the min. values obtained during the periods of idleness after harvesting and threshing were finished. T. M. CARPENTER

The protein catabolism at extraordinary altitudes. A contribution to the question of the limits of acclimatization at high altitudes. A. LOEWY. *Arbeitsphysiol.* **3**, 596-604(1930); cf. *C. A.* **25**, 988.—Ten urines obtained from 6 members of Dyhrenfurt's expedition to the Himalayas at altitudes between 5150 and 7300 m. and preserved in air-tight sterile bottles contg. powd. thymol were analyzed at Davos. Expressed in % of total N the constituents averaged: urea 75.4, ammonia 5.05, preformed creatinine 3.74, total creatinine 4.80, uric acid 2.22, amino acids 0.94 and undetd. N 12.5%. The urines were more nearly normal than those collected by Hopf (cf. *C. A.* **23**, 5223) in the second winter Olympic. This cannot be explained by the inhalation of O as only one sample was obtained under this condition and its compn. agreed well with that from the same person without previous inhalation of C. The approach to normality may be explained by the extensive acclimatization at the high altitudes. The acclimatization began at 2700 m. and the urines were collected 49 to 86 days later.

Meanwhile the subjects had successively gradually attained the high altitudes at which the urines were collected. T. M. CARPENTER

The anterior pituitary hormone. W. FALTA AND F. HOGLER. *Klin. Wochschr.* **9**, 1807–12(1930). H. EAGLE

Investigations in the role of the liver in the intermediary metabolism. KARL PASCHKIS. *Klin. Wochschr.* **9**, 1917–9(1930).—In liver damage, as, *e. g.*, in toxic jaundice, there is an abnormal increase in blood amino acids following the peroral admnistration of amino acids, suggesting that deaminization is a function of the liver H. EAGLE

Effect of temperature upon the height of contraction and time of maximal contraction of skeletal muscles. I. Frog muscles. KISUO SUGAI. *Tôhoku J. Exptl. Med.* **16**, 1–24(1930).—The time required for maximal contraction decreases with increasing temp. (10–40°); the temp. coeff. is 2 between 10° and 25°, but only 1.2 between 25° and 40°. The degree of contraction is usually a min. at 22–27°; it increases at either higher or lower temps.; occasionally it remains quite const., and in a third group decreases uniformly with temp. **II. Muscles of white guinea pigs.** *Ibid* 54–76.—Contrary to the results obtained with the muscles of poikilothermic animals, the extent of contraction of guinea pig striated muscle decreases with temp. (10–40°). The latent period and the time required for maximal contraction both show a similar decrease with temp., the temp. coeff. being 1.2 between 40° and 25° and 1.8 between 25° and 10°. At the same temps., the contractility gradually decreases, but the max. contraction time remains unaffected. H. EAGLE

Effect of temperature upon the contraction curve with several peaks. KISUO SUGAI. *Tôhoku J. Exptl. Med.* **16**, 25–53(1930). H. EAGLE

Studies in the internal secretion of the pancreas. XV. TAIZO KUMAGAI AND SATORU UKAI. *Tôhoku J. Exptl. Med.* **16**, 157–68(1930).—Aq. exts. from various portions of pigeon pancreas were tested for their hypoglucemic effect upon rabbits. Those prepd. from regions relatively rich in alpha cells were found to be distinctly more active, contrary to the theory of beta-cell activity. H. EAGLE

Indispensability of the suprarenal glands in causing nicotine hyperglucemia in rabbits. TATSUSABIRO INABA AND KOGORO OIKAWA. *Tôhoku J. Exptl. Med.* **16**, 169–77(1930).—Double splanchnicotomy does not affect nicotine hyperglucemia in rabbits, but removal of the suprarenals prevents it completely. H. E.

The vascular effect of tissue fluids. SABURO FUKAMI. *Tôhoku J. Exptl. Med.* **16**,

184–8(1930).—Perfusion of Ringer fluid through surviving tissue (rabbit leg) endows the fluid with vasodilating properties, not observed if H_2O or NaCl soln. is used. The vasodilating activity is most marked $1^1/_2$ hrs. after the fluid is prepd., and gradually disappears in the course of 24 hrs. H. EAGLE

The resorption of parenterally introduced emulsified fats. SEINOSUKE HOTTA. *Tôhoku J. Exptl. Med.* **16**, 311–20(1930).—The number of very fine granules seen in blood plasma (fat droplets) is an accurate measure of parenteral fat absorption paralleling the results obtained on chem. analysis. Absorption from serous cavities is very rapid, and is conditioned by the circulation of the underlying tissues. H. E.

Biochemistry and biophysics of the developing hen egg. I. Influence of humidity. ALEXIS L. ROMANOFF. Cornell Univ. Agr. Expt. Sta., *Mem.* **132**, 3–27(1930).—From the exptl. data it is concluded that the extreme conditions in the incubator, 80 and 40% relative humidity, have both direct and indirect influence on the developing chick embryo, as follows: The growth of the embryo was rather irregular, being somewhat hastened at high and retarded at low humidity. The cycles in the growth of the embryo were decidedly disturbed. The Ca metabolism in certain stages of the embryonic development was much better at high than at low humidity. The mortality of the embryo was noticeably increased during the 2nd critical period, at the 19th day of incubation, particularly at high humidity. The physicochem. constitution of the yolk sac was slightly changed; this might have affected the embryonic metabolism, leading to the low vitality of the embryo and to its susceptibility to environment. The water content of the shell membranes and the contents of the allantoic sac corresponded to the humidity condition; this might have made an obstruction to hatching through the restriction of free movement of the embryo and through the hindrance to pulmonary embryonic respiration. Bibliography. C. R. FELLERS

Effect of the estrus-producing hormone on the growth of the mammary gland. C. W. TURNER AND A. H. FRANK. Mo. Agr. Expt. Sta., *Research Bull.* **145**, 5–56 (1930).—In the normal rabbit after continued estrus, the mammary glands show extreme extension of the duct systems resembling the naked branches of a tree. If pregnancy or even pseudo-pregnancy now ensues, the ducts develop lobules contg. large nos. of alveoli, resembling the budding of leaves from the smaller branches. The daily injection of 20 rat units of the estrus-producing hormone recovered from pregnant-cow urine, for 30 days in male castrate rabbits and in female rabbits castrated previous to puberty caused the growth of the duct system of the glands equal to that produced during continued estrus in the normal female. The results obtained seem to warrant the conclusion, that the estrus-producing hormone will cause the growth of the ducts equal to that produced during estrus, that the rate of development is not hastened by increasing the dosage and that there was present in none of the oils used a hormone or hormones which would produce the type of growth characteristic of pregnancy. C. R. FELLERS

Basal metabolism of young women. HUGHINA MCKAY. Ohio Agr. Expt. Sta., *Bull.* **465**, 3–37(1930).—The Benedict-Roth metabolism app. was used to study the basal metabolism on 91 girls aged from 14 to 18 yr. O consumption averaged 197 cc. per min.; basal heat production 1364 cal. and av. basal cal. production was 25.4 per kg. Heat production per kg. decreased fairly regularly as age increased. No significant differences among the age groups were noted on O consumption. When age was disregarded, heat production per kg. decreased decidedly with increased wt. The overwt. group averaged 9% less and the underwt. group, 12% more per kg. than the entire group. Predictions of basal metabolism on surface area are less liable to error than those based on height or wt. Basal metabolism of young college women is somewhat higher in the spring than in autumn or winter. C. R. FELLERS

The effect of manganese on the growth of rats. V. E. NELSON, J. M. EVVARD AND W. E. SEWELL. *Proc. Iowa Acad. Sci.* **36**, 267(1929).—Mn in small quantities stimulated the growth of rats. The basal diet employed consisted of casein 18, yeast 12, cod-liver oil 5, salts (mixt. no. 185) 3.7 and dextrin 61.3. $MnSO_4.4H_2O$ was fed at 2 levels, 100 and 600 p. p. m. of ration. In 56 days the control gained 1.78 g. daily and consumed 434 g. of feed per 100 of grain. On the smaller Mn allowance the gain was 2.06 g., and the feed requirement was 391.4 g. for 100 gain. On the larger Mn allowance the figures were 1.69 and 458.5. Apparently the 600 parts of $MnSO_4.4H_2O$ per million inhibited growth. W. G. GAESSLER

Hydrolysis of levorotatory substance in human milk. M. POLONOVSKI AND A. LESPAGNOL. *Compt. rend. soc. biol.* **101**, 64–5(1929); *Physiol. Abstracts* **14**, 373.—A levorotatory non-reducing lactoside, a glucoprotein, exists in human milk, which is converted to a reducing substance by hydrolysis. G. G.

Basal metabolism as a function of temperature. C. KARPER. *Compt. rend. soc. biol.* **101**, 708–10(1929); *Physiol. Abstracts* **14**, 653.—The influence of the surrounding temp. on the min. heat production of pigeons after a 26 hrs.' fast has been detd. By a simple mechanism of adaptation the exchanges in a pigeon may be diminished by 29.4%. The adaptation is slow, and may take several weeks for completion. In contrast with this slow mechanism is the rapid chem. regulation setting up increased heat production when the temp. is lowered. G. G.

Coagulation of blood and cholesterol content. L. BUGNARD. *Compt. rend. soc. biol.* **102**, 291–3(1929); *Physiol. Abstracts* **14**, 552.—The cholesterol of serum is greater than that of plasma. The coagulation of blood under oil or in air is accompanied by an increase of cholesterol in the fluid phase. G. G.

Mechanism of concentration of urinary indoxyl. G. LAROCHE, A. GRIGAUT AND P. DELILLE. *Compt. rend. soc. biol.* **102**, 532–4(1929); *Physiol. Abstracts* **15**, 38.—Parenteral injection of isotonic saline soln. in the dog leads to a lowering of urinary indoxyl. Ingestion of water by the mouth increases it because of the absorption of indole from the alimentary canal. Peptone shock causes an augmented output. Tissue disintegration with transformation of tryptophan to indole may account for some of the increase. This would imply the endogenous formation of indole, which cannot be demonstrated. G. G.

Cholesterol regulation in the lung. L. BUGNARD. *Compt. rend. soc. biol.* **102**, 550–1(1929); *Physiol. Abstracts* **15**, 18; cf. *C. A.* **24**, 647, 4816.—The distribution of cholesterol in the blood depends on the reaction. When the acidity is increased the amt. of cholesterol in the plasma rises, the effect being explained by a transference of cholesterol from the corpuscles. Diminution of CO_2 in the lung is accompanied by the reverse change in the cholesterol distribution. The distribution seems to be a factor in maintaining the physicochemical equil. and the p_H of the blood. G. G.

Oxidation-reduction potential of the vitreous humor. E. REDSLOB AND P. REISS. *Compt. rend. soc. biol.* **102**, 1060–2(1930); *Arch. phys. biol.* **7**, 221–5(1930); *Physiol. Abstracts* **15**, 145.—The oxidation-reduction potential of the vitreous humor in the rabbit was measured by the injection of indicators and by the insertion of a fine platino Ir point with an indifferent electrode on the skin for elec. measurement. The results of the 2 methods agreed well. A potential of +110 mv. was found, which corresponds with an r_H of 19.1 for a p_H of 7.6. Arrest of the circulation caused a fall of potential to +51 mv., corresponding to an r_H of 16.9. G. G.

Reactions of ovary to placental injections. M. KLEIN. *Compt. rend. soc. biol.* **102**, 1068–9(1930); *Physiol. Abstracts* **15**, 181.—Exts. of total placenta cause a great disturbance of the ovary in the rabbit. The changes resemble those obtained with hypophysin. The effects are produced with human placenta at all stages of pregnancy and at term. G. G.

Is the active placental substance a hypophyseal hormone? M. KLEIN. *Compt. rend. soc. biol.* **102**, 1070–1(1930); *Physiol. Abstracts* **15**, 181 2.—Hemorrhagic follicles and corpora lutea are found in the ovary after injection of the placental ext. These changes are supposed by some workers to be sp. tests of hypophysin. The increased thyroid activity described as resulting from injections of hypophysin did not occur as a result of placental injection. It is probable that the placenta contains a substance which acts on the ovary but which is not hypophysin. G. G.

Acidosis in pregnancy. E. L. SOLAI, J. DALSACE AND M. GIRARDOT. *Compt. rend. soc. biol.* **103**, 111–2(1930); *Physiol. Abstracts* **15**, 184.—Uncompensated acidosis has been demonstrated in albuminuric pregnancy. Now it is shown that acidosis exists to some extent toward the end of normal pregnancy. It is greatest in labor and disappears after parturition. There is a lowering of p_H and of the alk. reserve. In preeclamptic conditions the p_H and alk. reserve are lowest. G. G.

Oxytocic properties of woman's blood during parturition. J. FONTES. *Compt rend. soc. biol.* **103**, 349–50(1930); *Physiol. Abstracts* **15**, 119.—The oxytocic substance in woman's blood must be a fetal product or a product obtained from fetal accessory structures, as it disappears a few hrs. after parturition. The blood of the umbilical cord is not active, while that from the placental site of the uterus is. The placenta may be the seat of formation of the oxytocic substance. The oxytocic element is the detg. factor in setting up labor pains. G. G.

Secretory phenomena in the thyroid of birds. P. FLORENTIN AND M. WEIS *Compt. rend. soc. biol.* **103**, 601–3(1930); *Physiol. Abstracts* **15**, 179–80.—In certain birds massive degeneration of the parenchyma of the thyroid was observed. The débris is poured directly into the circulation, cellular emboli being seen in the small vessels. Amitotic multiplication is supposed to be the method of regeneration. The

analogy with mammalian thyroid processes is marked. The phenomenon seems to be connected with changes in the sexual organs. G. G.

Difference in cerebral effects of a new thyroid extract and thyroxine. G. FUCHS. *Compt. rend. soc. biol.* **103**, 603–5(1930); *Physiol. Abstracts* **15**, 180.—An ext. has been made from the thyroid of vagotonic animals which acts on psychomotor centers in lowering their chronaxie. It contains a hormone which is different from that affecting metabolism. Thyroxine does not lower the chronaxie of the nervous centers. G. G.

Substances extracted from the suprarenal glands by hydrogen peroxide. J. STEFL. *Compt. rend. soc. biol.* **103**, 650–2(1930); *Physiol. Abstracts* **15**, 180.—In extg. the cortical hormone of the suprarenal gland, adrenaline may be excluded by using H_2O_2. The ext. contains no lipoids, but choline is abundant. The alc. ext. contains lipoids and a crystallizable substance. The crystallizable substance is supposed to be identical with the oxidation product of adrenaline. Choline exists only in the peroxide ext., not in the alc. It probably arises from the decompn. of lecithin. G. G.

Remarks on the work of Mond and Netter "does the ionic permeability of muscle change during muscular activity?" E. ERNST. *Arch. ges. Physiol.* (*Pflügers*) **226**, 243(1930); cf. *C. A.* **24**, 5354.—Polemical. ARTHUR GROLLMAN

Hemin, bilirubin and porphyrins. HANS FISCHER. *Naturwissenschaften* **18**, 1026–37(1930); cf. *C. A.* **25**, 526.—An elaborate review of the present knowledge of the chemistry of blood pigment and related chem. compds.; numerous references are given. B. J. C. VAN DER HOEVEN

Morphology of the porphyrins. M. BORST. *Naturwissenschaften* **18**, 1038–41 (1930).—A review of recent work on morphological distribution of porphyrins and derivs. (cf. Borst and Königsdörffer, Untersuchungen über Porphyrine, Leipzig, 1929). B. J. C. VAN DER HOEVEN

Proteoclastic function of the thyroid. M. LOEPER, A. LEMAIRE AND J. TONNET. *Compt. rend. soc. biol.* **102**, 279–80(1929); *Physiol. Abstracts* **14**, 580.—The thyroid gland breaks up proteins. Nucleo-albumins (precipitable by AcOH) are less abundant in the venous than in the arterial blood. Serine is more abundant in the venous blood. The amino acids are less abundant in the efferent blood. Fresh thyroid ext. breaks up albumins *in vitro*. E. C. K.

Rest-nitrogen percentage of the blood of natives and of Europeans in the Tropics. W. RADSMA. *Mededeel. Dienst Volksgezondheid Nederland.-Indië* **19**, Pt. 2, 227–32 (1930).—A series of urea estns. with undernourished natives resulted in an av. of 23 mg. %; from 3 to 4 hrs. after the last meal at 10 or 11 A. M., the av. was 25.8 mg. %. The blood examd. was capillary blood from the fingertip. J. A. KENNEDY

Gasometric determination of the relative affinity constant of carbon monoxide and oxygen in whole blood at 38°. J. I. SENDROY, S. H. LIU AND D. D. VAN SLYKE. *Bull. soc. chim. biol.* **12**, 532(1930).—Three normal and 3 pathol. samples of human blood gave a value of 210 for the affinity const. K (p_{O_2}/p_{CO}) = ($HbCO/HbO_2$), and for 10 samples of beef blood K = 179. All values found were within 2.5% of the av. C. G. KING

Food balance and nutrition. LUCIE RANDOIN. *Bull. soc. chim. biol.* **12**, 815–26 (1930); cf. *C. A.* **24**, 5805.—Pigeons receiving 66% carbohydrate on a vitamin-B free diet died in 17–27 days, but when on a carbohydrate-free diet (54% protein) they survived 3 months. Similarly rats died in 30–60 days or survived 4 months. Expts. also indicate a needed balance of mineral salts and carbohydrate. Details concerning purification of the diets are not given. C. G. KING

Relationship between electrical differences of potential in the skin and normal basal metabolism. CHARLOTTE PURDY, A. FRANCES JOHNSON AND CHARLES SHEARD. *Science* **73**, 46–9(1931). W. D. LANGLEY

Regulation of cholesterolemia. L. BUGNARD AND C. SOULA. *Compt. rend.* **191**, 1382–4(1930).—The regulation of cholesterolemia is an automatic function of the blood tissue. It is accomplished by the globular cholesterol existing in this tissue although it is neither generated nor destroyed by it. The mechanism of such regulation is purely a physical one and depends upon the cholesterol circulating generally in the cellular constituents of the blood and in the plasma. B. S. LEVINE

The work of the kidney in the production of urine. HENRY BORSOOK AND HOWARD M. WINEGARDEN. *Proc. Nat. Acad. Sci.* **17**, 3–12(1931).—Summary: (1) The work of the kidney in the excretion of urine is analyzed by means of the second law of thermodynamics. (2) It is shown that the work performed by the normal kidney in man in the excretion of urine is of the order of magnitude of 0.7 g. cal. per cc. of urine, or 70 g. cal. per g. of N excreted. B. S. LEVINE

The energy cost of the excretion of urine. HENRY BORSOOK AND HOWARD M.

WINEGARDEN. *Proc. Nat. Acad. Sci.* **17**, 13–28(1931).—Summary: (1) The work of the kidney in the excretion of urine is analyzed by means of the second law of thermodynamics. It is shown that the production of either hyper- or hypo-tonic urine entails work on the part of the kidney. The excretion of a urine which is the same as the plasma in all details incurs no work by the kidney. (2) The energy consumed by the kidney in man in the production of urine was found to be 6–11 kg. cal. per g. of N excreted. (3) It is shown that the normal healthy kidney considered as a chem. machine possesses a great capacity for work, but performs its work with an "efficiency" probably not greater than 1–2%. (4) The effect of disease is to reduce markedly the capacity of the kidney for work. B. S. LEVINE

Gas tensions in the tissues. J. ARGYLL CAMPBELL. *Physiol. Rev.* **11**, 1–40 (1931).—General review covering diffusion, absorption, quant. measurement and other problems concerning gases in body tissues, cavities and secreted fluids. Extensive bibliography. E. R. LONG

Factor influence on oxidative and lytic systems. W. LOELE. *Virchow's Arch. Path. Anat.* **279**, 207–13(1930). In the oxidation system: OH + α-naphthol + NH_2-(COOH) + COH + Fe^{+++} a variety of amino acids may take the place of the glycocoll. This artificial oxidation system, in its susceptibility to heat, prolonged standing, $ZnCl_2$, etc., behaves much like the cell oxidase supposed to function in the granules of eosinophilic leucocytes. Amino acids function in tryptic systems *in vitro*, inhibiting the action of alkali. While *in vitro* the groups COH and NH_2(COOH) both inhibit the action of alkali, they are themselves antagonistic, the inhibiting action of COH being removed by NH_2. In the formation of blood cells peptic processes occur in the lymphocytes and tryptic processes in the granular leucocytes and red blood corpuscles. The formation of these cells may be modified by changing the OH concn. of tissue, and by treatment with aldehydes, amino acids or ferric salts. E. R. LONG

The equilibrium between cerebrospinal fluid and blood plasma. III. The distribution of calcium and phosphorus between cerebrospinal fluid and blood serum. H. HOUSTON MERRITT AND WALTER BAUER. *J. Biol. Chem.* **90**, 215–32(1931). Normal serum contains from 9.35 to 10.6 mg. of Ca per 100 cc. (av. 10.0 mg.) while the Ca content of cerebrospinal fluid is approx. ½ this amt. (4.5 to 5.23 mg., av. 5 mg.) The Ca content varies directly with the serum protein in such a way that there is no significant change in the ratio with changes in the serum protein. In meningitis there is a slight diminution in serum Ca and an increase in cerebrospinal fluid Ca which is accounted for by increased permeability of the meninges and the choroid plexus with a resulting increased protein content in the spinal fluid. There is a definite decrease in serum Ca at the end of pregnancy; the amniotic fluid Ca averages 6.59 mg. per 100 cc. In non-suppurative diseases of the central nervous system the Ca content of both serum and spinal fluid is normal; the spinal fluid P content varies between 31 and 45% of the serum P (av. 38%) in these diseases while in suppurative conditions the ratio varies between 35 and 123% (av. 40%). The serum and spinal fluid Ca content of cats is slightly higher than in humans, the spinal fluid Ca averaging 54% and the aqueous humor 60% of the serum Ca. **IV. The calcium content of serum, cerebrospinal fluid and aqueous humor at different levels of parathyroid activity.** *Ibid* 233–46. The cerebrospinal fluid Ca remains markedly constant in spite of a well-marked change in the serum Ca level, the striking lowering of serum Ca in parathyroid tetany and its sustained elevation following parathormone administration being without appreciable effect on the spinal fluid Ca level. Injection of parathyroid hormone causes only a slight increase also in the Ca content of the aqueous humor (0.6 mg.). If one accepts the cerebrospinal fluid as a dialyzate in osmotic and hydrostatic equil. with the blood plasma, the data would indicate that variations in serum Ca occurring during parathyroid tetany or following the administration of parathyroid gland ext. are chiefly and perhaps wholly limited to the non-diffusible Ca. Variations in serum Ca associated with different levels of serum protein involve both the diffusible and non-diffusible Ca. Bibliography of 55 references. A. P. LOTHROP

Studies in hyperthermia. II. The acid-base equilibrium in hyperthermia induced by short radio waves. FRITZ BISCHOFF, M. LOUISA LONG AND ELSIE HILL. *J. Biol. Chem.* **90**, 321–9(1931); cf. *C. A.* **24**, 2784.—"With the exception of a fall in blood vol., which is probably not a direct effect, no difference in effect was noted between raising the body temp. by placing the subject in the field of condenser plates in circuit with a short-wave radio transmitter and in raising the body temp. by means of diathermy, warmed air or hot water baths. Of fundamental importance was the loss of CO_2. The p_H of the blood became more alk., there was a shift of bases to the blood proteins and an increased oxygenation of the hemoglobin of venous blood. No signifi

cant change in the non-protein N constituents of the blood was noted. No evidence was obtained that the body was attempting to compensate for the condition of alkalosis through the urinary or perspiratory excretions." **III. The phosphorus equilibrium.** FRITZ BISCHOFF, L. C. MAXWELL AND ELSIE HILL. *Ibid* 331–9.—"No P is eliminated in the perspiration during a hyperthermia induced by radio waves. The decrease in the rate of urinary P excretion is accounted for by the decrease in P elimination with increase in metabolism and the conversion of inorg. to org. P in the blood with an alk. shift of blood p_H. The decreased rate of urinary N excretion is accounted for by the increased N elimination through the perspiration." A. P. LOTHROP

The action of general cold stimuli (sea bathing) on the resistance of erythrocytes. A. CHIATELLINO. *Arch. sci. biol.* (Italy) **15**, 346–55(1930); cf. *C. A.* **24**, 4824.—Cold stimuli such as sea bathing cause an increase in the no. of red blood corpuscles and a definite but slight decrease in the resistance of the corpuscles to hemolysis. P. M.

The place of origin of the biliary pigment. EMILIO BECCARI. *Arch. sci. biol.* (Italy) **15**, 356–95(1930).—A review. PETER MASUCCI

The reaction of articular tissues. BRUNO BORGHI. *Minerva med.* **1930**, II, 913–7.—The object was to see whether intensive work, immobility and the local action of heat and cold have the power to modify the p_H of articulations. One knee of the rat was used for the study, while the other was kept as a control. The p_H was detd. by means of phenol red which was injected intraperitoneally into the rats. The following results were obtained: Intense work changed the tissues of articulation toward the alk. side; immobility did likewise at first, but later the reaction of the tissues changed toward the acid side of the normal. The local application of heat increased the alky. Cold produced slight and inconst. changes toward the acid side which was revealed by the diminution of the buffer value of the tissues toward acids. The mechanism of these changes and their significance in the general pathology of articulation are discussed PETER MASUCCI

The curve of alveolar carbon dioxide tension during voluntary apnea. GIORGIO GIORGI *Arch. ital. biol.* **84**, 11–22(1930).—For the same individual there is an av. value for alveolar CO_2 tension beyond which it is impossible to maintain apnea. This max. alveolar CO_2 tension varies for different individuals, but for the same individual it is fairly const. S. MORGULIS

Influence of the liver on the function of the heart. A. RONCATO. *Arch. ital. physiol.* **84**, 23–31(1930).—Blood perfused through the liver produces a marked hemodynamic effect upon the isolated heart. The perfusion arrangement is such as to permit the inclusion or exclusion of the pancreas, and this shows that the pancreas does not contribute to the effect upon the heart of the blood circulating through the liver. No conclusion is drawn as regards the nature of the substance given off by the liver which may be a hormone, or some nutritive factor furnished by the liver to the heart. Finally, it is also considered that the liver may detoxicate the blood which passes through it before reaching the heart and thus increase its action upon the contraction of the heart. S. MORGULIS

Studies of carbohydrate metabolism of blood and organs with the aid of a new colorimetric method. I. The presence of different hexoses besides glucose in human blood and their formation in vitro. ZACHARIAS DISCHE. *Biochem. Z.* **229**, 169–95 (1930).—Two methods were employed for the detn. of the blood sugar. A part of the blood is deproteinized with 25%, and another part with 10% CCl_3CO_2H. After remaining overnight this is centrifuged. It has been definitely established that no free sugar is retained in the ppt., nor do any substances pass into the fluid which affect the color reactions utilized in the sugar detn. Added glucose has always been quantitatively recovered. The color reactions were produced with diphenylamine-HCl or with indole-H_2SO_4. The former reaction was so modified that it included all hexoses and not merely fructose. For this purpose to 1 part of the sugar soln. are added 2 parts of Rothenfusser's reagent (100 cc. concd. HCl, 80 cc. glacial AcOH, 20 cc. of 10% alc. diphenylamine); this is then heated in the boiling water bath 3, 10 or 30 min. The ketoses show a much stronger coloration than aldoses, the difference being greater the shorter the time of boiling. By the indole-H_2SO_4 reagent the relative color intensities for various sugars are as follows: glucose 100, fructose 125, Harden-Young ester 100, mannose 70 and galactose 75. The results by the former reaction are invariably higher (10–150%) than by the latter. In some instances the diphenylamine-HCl procedure gave variable results depending on whether the heating was for 10 or 30 min, which is regarded as an indication that blood contains 2 other hexoses besides glucose, an aldose and a ketose, which are designated as the "additional sugar." Following a large glucose dose the intensity of both the diphenylamine-HCl and indole-H_2SO_4 reaction gen-

erally increases to the same extent, so that only the glucose but not the "additional sugar" of the blood is raised under these circumstances, but occasionally there is an increase also in the "additional sugar." An hr. after the injection of 20–30 units of insulin both glucose and the "additional sugar" disappear, but the latter disappears more rapidly. Incubating blood at 37° for 2 hrs. causes practically all the "additional sugar" to disappear. From the behavior of fluoride or citrate blood kept for several hrs. at room temp. it is evident that a ketose sugar is formed, which disappears more quickly than glucose when the blood is kept in the incubator. Addn. of glucose to citrated blood causes the formation of a ketose as well as an aldose. The newly formed ketose is present only in the red cells whereas the preformed "additional sugar" is practically equally distributed between cells and plasma. The formation of the ketose in blood at room temp. is much increased through the addn. of Na_2HPO_4, and it is believed that this ketose is really a hexosephosphate ester. S. MORGULIS

Influence on the development of the female sex organs of hyper-interrenalization. CARL MÜLLER. *Endokrinologie* **8**, 5–14(1931).—Expts. were performed on female rats exactly 3 weeks old. Some of these young rats were thymectomized, and only about 15% of the operated animals were lost. A special ext. of the adrenal bodies was used to inject some of the intact and of the thymectomized rats. For this purpose very fresh beef suprarenal glands were freed from fat, etc., and the cortex, carefully sepd. from the medulla, was ground fine in a few cc. 0.9% NaCl. The thick, reddish pulp obtained from about 150 g. substance is boiled in an Erlenmeyer flask for 10 min. on the water bath to remove proteins. This is filtered through gauze, about 30 cc. soln. being obtained. Traces of adrenaline are removed by passing air through the ext. which is now neutralized with 0.05 *N* NaOH. Every 2–3 days 0.5 cc. of this was injected. These injections of the cortical ext. produced a typical strong inhibition of development of the external as well as internal female sex organs. In the ovary defective development of the ova was observed and absence of normal corpora lutea. S. MORGULIS

Inactivation by proteolytic enzymes of the anterior hypophysis hormone obtained from pregnant urine. M. REISS, A. SCHÄFFNER AND F. HAUROWITZ. *Endokrinologie* **8**, 22–4(1931).—Expts. were made with the following proteolytic enzymes: amino polypeptidase, carboxypolypeptidase, pepsin, inactive trypsin and activated trypsin. Only the activated trypsin brought about complete destruction of the hormone. S. MORGULIS

The significance of the bile acids in the carbohydrate metabolism. IX. The effect of bile acids on the sugar assimilation. SEI FUZITA. *J. Biochem.* (Japan) **12**, 383–91(1930).—The glycogen-forming capacity of the fasting rabbit liver from different monoglucides decreases in the following order: *d*-fructose, *d*-glucose, *d*-mannose and *d*-galactose. The glycogen forming capacity in this series can be raised on the av. 42–52% by the administration of cholic acid. Fructose yields the greatest glycogen production both with or without cholic acid; in point of extent of the glycogen formation with cholic acid this is followed by glucose, mannose and finally galactose. The lowering of the excretion threshold for these various sugars under the influence of cholic acid is therefore to be attributed to its stimulation of glycogen formation in the liver. S. MORGULIS

Studies on the nature of the prophyrin appearing in urine following ingestion of chlorophyll. YASUO NAKAMURA. *J. Biochem.* (Japan) **12**, 475–85(1930).—Spectroscopic studies as well as biol. tests show that urine porphyrin following the ingestion of chlorophyll is isomeric with blood porphyrin. The urobilin output after chlorophyll ingestion is always increased. S. MORGULIS

The site of ammonia production. A. FØLLING. *Skand. Arch. Physiol* **61**, 23–6 (1931).—F. experimented upon himself, on an ordinary diet, and in a condition of acidosis caused by NH_4Cl or alkalosis by $NaHCO_3$. The plasma NH_3 was detd. by the Parnas method, the rate of kidney filtration by Rehberg's method and the urinary NH_3 in hourly samples. So long as the urine is more acid than p_H 7.8 more NH_3 is found in the urine than is filtered through the kidney during the same time, so that the NH_3 must be formed by the kidney. The results of analysis also allow the calcn. of the concn. of undissocd. NH_4OH in plasma and urine, according to which the latter is 10 times as great as the former, thus precluding any possibility of a direct diffusion from plasma into urine. S. MORGULIS

Further observations on the depressor substance in brain tissue. RALPH H. MAJOR AND C. J. WEBER. *J. Pharmacol.* **40**, 247–52(1930); cf. *C. A.* **24**, 2199.—The depressor substance is adsorbed on Lloyd's reagent from a brain ext. and then freed by treatment with $Ba(OH)_2$. The soln. is further purified by pptn. with phosphotungstic

acid and $AgNO_3$. The final soln. produces a fall in blood pressure in dogs before or after atropinization. It gives a positive Sakaguchi, and a negative Pauly, reaction. The substance is not histamine, choline or acetylcholine. C. RIEGEL

G—PATHOLOGY

H. GIDEON WELLS

Chloride determinations in cases of intestinal obstruction. M. PAGET. *Bull. soc. chim. biol.* **12**, 409–10(1930).—Chloride detns. in cases of high or low obstruction of the intestine should be made on whole blood when the alk. reserve is increased and on the serum when it is normal. B. C. A.

Magnesium and calcium in the liver of hyperthyroidized animals. M. CAHANE. *Compt. rend. soc. biol.* **100**, 577–8(1929).—With guinea pigs the increase was 0.0021 and 0.0015%, resp. B. C. A.

Relation between changes in the alkali reserve and relative chlorine and sodium contents of the blood in experimental immobilization of the intestine and in histamine shock. F. D. ALSINA. *Compt. rend. soc. biol.* **100**, 1098–1101(1929).—The changes in the alkali reserve are accompanied by a relative increase in blood Na and decrease in blood Cl. B. C. A.

Dextrose and normohemolysins. I. DJURICIC. *Compt. rend. soc. biol.* **100**, 1224–5 (1929).—Dextrose has no influence on hemolysis by hemolysin; hence the mechanism is not that in hypertonia and is not accompanied by colloidal changes of the proteins of the surface layer. B. C. A.

Gaseous exchange in fever caused by naphthylamine-yellow or by β-tetrahydronaphthylamine. J. DADLEZ AND W. KOSKOWSKI. *Compt. rend. soc. biol.* **100**, 1234–6, 1238–40(1929). B. C. A.

Nature of the toxic product arising from closure of the intestine. A. BLANCHETIERE AND L. BINET. *Compt. rend. soc. biol.* **101**, 14–7(1929).—On occlusion of the intestine there is present a single-chain substance of proteose character, probably arising from the decarboxylation of leucine; it is possibly isoamylamine. B. C. A.

Action of formaldehyde, hydrogen peroxide and white phosphorus on tuberculin. J. F. HEYMANS AND C. HEYMANS. *Compt. rend. soc. biol.* **101**, 153–5(1929).—Tuberculin, which is not decomposed by the above reagents, is exceptional among proteins. B. C. A.

Affinity of hemoglobin for oxygen in anemia. G. LITARCZEK, H. AUBERT AND I. COSMULESCO. *Compt. rend. soc. biol.* **101**, 220–1, 222–3(1929).—The affinity of hemoglobin for O is reduced in anemia. The ratio of $1/k$ to $C_H \times 10^8$, where k is the dissocn. const. of the oxyhemoglobin, is abnormally high in anemia. B. C. A.

Bile protein in diabetes. J. GAVRILA AND A. MOGA. *Compt. rend. soc. biol.* **101**, 404–6(1929).—In diabetes the bile protein is increased. B. C. A.

Susceptibility and resistance to tar cancer, an experimental study. J. MAISIN. *Ann. Surgery* **93**, 180–9(1931).—Tar cancer is the result of a local irritation as well as of a general intoxication. Certain mineral salts (Mg, Cu) used in convenient doses are capable of delaying the appearance of cancer and of lowering the percentage of induced tumors. Other salts, *i. e.*, salts of radioactive metals, have the opposite effect. Diet can influence the appearance and evolution of tar cancer. The liver diet activates the development of cancer. It is probable that other diets would retard its appearance. Vitamin A adsorbed in addn. to a normal alimentation has no inhibitive effect on the appearance of cancer. Preceding closely the development of tar cancer and during its evolution, the metabolism of fats is deficient and the variations of the cholesterolemia are marked. The same variations are to be noticed after repeated ionium injections. RACHEL BROWN

Dehydration in intestinal obstruction. GAVIN MILLER. *Edinburgh Med. J.* **38**, 47–53(1931).—In high simple obstruction in dogs, death is caused by loss of intestinal secretion causing dehydration and loss of Na and Cl ions. Only the blood plasma and interstitial fluid are lost. The intracellular fluid is maintained by an ionic concn. consisting mainly of H_2PO_4 and K. These are not lost in the gastrointestinal secretion and so dehydration does not impair the intracellular fluid. RACHEL BROWN

Experiences with a high carbohydrate-low calorie diet for the treatment of diabetes mellitus. I. M. RABINOWITCH. *Can. Med. Assoc. J.* **23**, 489–98(1930).—A report from the clinical point of view is given of a diet such as the title indicates. Provided the fat content is kept very low and the cal. value is within the min. requirements, it is possible, in the majority of cases, to make the diet of the diabetic quite attractive without the use of insulin. Where insulin is necessary, the dosage and frequency of

administration are less than with diets ordinarily in use. Special articles of food are not necessary. Low plasma cholesterol and N retention in the early stages are characteristic metabolic features assocd. with the treatment. A. T. CAMERON

Chloropenia with excess of tissue chlorine in cirrhoses. H. THIERS. *Compt. rend. soc. biol.* **101**, 475–6(1929); *Physiol. Abstracts* **15**, 36; cf. *C. A.* **24**, 5370.—In alc. cirrhosis of the liver the following syndrome is described: (1) diminution of Cl in blood, (2) normal or raised alk. reserve, (3) urea and non-protein N diminution in blood, (4) excess of Cl in tissues. The hepatic lesion plays a part in this. It is not attributable to the same mechanism as in nephritis. H. L. D.

Superventilation tetany. FRIEDRICH HOLTZ. *Z. physiol. Chem.* **194**, 76–80(1931).—The tetany resulting from a prolonged period of voluntary forced breathing is accompanied by a lowering of the phosphate content of the serum. This may drop to a value as low as $^1/_3$ of the normal, while the Ca remains normal. A study was made of the effect on nervous excitability by measuring a low-voltage current in milliamperes required to produce tremors in the tibial nerve. No fundamental difference was observed between normal and epileptic subjects except that epileptics reached the excitable stage somewhat sooner. A. W. DOX

Disturbances in the carbohydrate metabolism in Basedow's disease. BERNHARD KUGELMANN. *Klin. Wochschr.* **9**, 1533–4(1930).—Thyreotoxic patients given 100 g. of levulose *per os* show an appreciably higher and more prolonged curve, presumably due to functional liver insufficiency. H. EAGLE

An experimental contribution to the serodiagnosis of carcinoma. I. The use of a scale-photometer in the albumin-A reaction of Kahn. W. BACHMANN. *Klin. Wochschr.* **9**, 1540–1(1930).—The demonstration of normal quantities of albumin A in the serum is strong presumptive evidence for the absence of carcinoma. **II. The comparison of the Kahn method of albumin-A determination by scale-photometric measurement with the modified Botelho reaction.** W. BACHMANN AND FR. SCHMIDT. *Ibid* 1541–3(1930). A Kahn estimate of albumin-A over 32 signifies the absence of cancer; readings of 32–30, with the Botelho M or Z tests negative, make carcinoma improbable. Kahn < 32, and positive Botelho M and Z tests are strong evidence for the existence of cancer; Kahn < 30, and Botelho tests negative or conflicting signify possible cancer. It is important to regulate the p_H in the Botelho tests. H. EAGLE

Eclampsia and ion economy. H. ROSSENBECK. *Klin. Wochschr.* **9**, 1545–7(1930).—In eclampsia Na leaves the blood and goes into the tissues, there is also a relative increase in muscle Ca and a decrease in K. In the liver there is an increase of Na and K and a decrease in Ca. There is a theoretical discussion as to the significance of these findings. H. EAGLE

The clinical significance of the porphyrins. HUGO KAMMERER *Klin. Wochschr.* **9**, 1658–63(1930).—A critical analysis of the literature. H. EAGLE

Causal relationship and metabolic effects in diseases of abdominal organs and kidneys. SIGURD FREY. *Klin. Wochschr.* **9**, 1678–81(1930). H. EAGLE

Organ-antibody formations in human beings. OEDRON FISCHER AND FELIX GEORGI. *Klin. Wochschr.* **9**, 1817–9(1930).—Spirochetes grown in a rabbit brain medium and injected into humans cause the appearance of antibodies which react with an alc. ext. of either spirochetes or human brain. Spirochetes grown on a rabbit-kidney medium, and injected into humans, cause the appearance of antibodies against an alc. ext. of beef kidney, against sheep red blood cells, and against spirochetes. Absorption of this latter serum with sheep red cells removes its reactivity for the sheep cells as well as for the kidney, but leaves undiminished its reactivity with the spirochetes. The greater reactivity of the kidney-spirochetes antisera for spirochetes grown on a kidney medium is not affected by this absorption. F. and G. conclude (1) that sheep red cells, rabbit kidney and beef kidney contain common receptors, which may or may not be identical with the Forssman receptor; (2) that organ-specific antibodies may be induced in humans (anti-brain, anti kidney), which are not species specific; (3) that the difference between spirochetes grown on kidney and brain media, manifested by their greater reactivity with the homologous antisera, are not dependent upon the organ antibodies present in these sera. It is highly significant that none of these anti-spirochetal sera is Wassermann-positive. H. EAGLE

Decrease of the urine chloride in acute fibrinous lung involvement. F. REICHL. *Klin. Wochschr.* **9**, 1860–2(1930). H. EAGLE

The significance of elastin in icterus. F. ROSENTHAL. *Klin. Wochschr.* **9**, 1909–13(1930).—In jaundice, there is not a uniform satn. of the body by the bile pigments, but a selective absorption detd. by the affinity of the various organs for bilirubin. Thus, in dogs with exptl. jaundice (toluenediamine), despite a very high blood bilirubin,

the bilirubin content of the spleen, heart, muscle, fat, brain, etc., is minimal; while the liver, kidney, skin conjunctive heart valves, vascular intima and lungs contain large quantities. The bilirubin content of the liver and kidney is probably due to their excretory function, while the great affinity of the other tissues is detd. chiefly by their high content of elastic fibers. *In vitro*, these fibers absorb bilirubin from soln. In jaundiced skin, conjunctival, nuchal ligament, etc., the pigment cannot be extd. by alc., acetone or $CHCl_3$ save in small quantities, while it is readily extd. from liver or kidney. Apparently, elastin enters into a firm combination with bilirubin. It should be emphasized that the foregoing holds only for acute exptl. jaundice. H. EAGLE

The iodine-deficiency theory of goiter. C. ALEXANDER HELLWIG. *Klin. Wochschr.* 9, 1914–6(1930).—See *C. A.* **24**, 3052. H. EAGLE

Icterus neonatorum gravis. H. KLEINSCHMIDT. *Klin. Wochschr.* 9, 1951–4 (1930).—The disease is characterized by a high degree of erythroblastosis. The large quantity of hematin in the blood and the pronounced siderosis both indicate toxic destruction of the blood. Early transfusion is suggested. H. EAGLE

Acid-base balance in gastric and duodenal ulcer. F. REICHE AND F. FRETWURST. *Klin. Wochschr.* 9, 1954–9(1930).—The authors cannot confirm the findings of Balint that there is acidosis in cases of duodenal ulcer. H. EAGLE

Testing the detoxicating function of the liver. MICH. SCHOUR AND CEL. ROSENGARTEN. *Klin. Wochschr.* 9, 1968(1930).—With increased putrefaction and a normally functioning liver, there may be indicanuria, but indole or urorosein does not appear. In cases of liver insufficiency, indican decreases, and the other 2 substances appear in the urine, the quantity depending upon the degree of intestinal putrefaction and of liver damage. H. EAGLE

Studies in the experimental autohemolysin of rabbits. SHUNYO SUNAMI. *Tôhoku J. Exptl. Med.* **16**, 277–97(1930).—A mixt. of lecithin and pig serum injected intravenously into rabbits causes the production of autohemolysin. A certain proportion of rabbits normally contain autohemolysin in the serum: and only a certain proportion contain the necessary receptor groups in the red cells which can combine with the antibody. H. EAGLE

The distribution of water in the animal body. I. Distribution of water in the rabbit with a functional impairment of the thyroid gland. HYOE KUSAKIRI AND KENJIRO TAKEDA. *Tôhoku J. Exptl. Med.* **16**, 329–40(1930).—In hyperthyroidism, the body as a whole loses water, particularly the skin; in hypothyroidism there is water retention, also chiefly in the skin Variations in the other organs are not const. H. EAGLE

Studies in the colloid-osmotic pressure of the blood in normal and pathological conditions. III. Colloid-osmotic pressure of the blood in hypotension and hypertension. FUSAKICHI NAKAZAWA AND JIRO IZUMI. *Tôhoku J. Exptl. Med.* **16**, 341–51(1930); cf. *C. A.* **24**, 2801.—In both hypotension and hypertension without kidney involvement there is no significant change in the colloid osmotic pressure of the blood or in the osmotic pressure per gram of serum protein. In hypertension with kidney damage, however, the total colloid osmotic pressure is very low, even though the serum protein may show no striking change. **IV. Colloid-osmotic pressure of the blood in experimental kidney damage.** KOTARO KIMURA AND FUSAKICHI NAKAZAWA. *Ibid* 352–60.—Following poisoning with cantharidin or U, the total colloid-osmotic pressure of dog serum is strikingly low, as is also the pressure per unit serum. In marked contrast following U poisoning, the colloid-osmotic pressure of the urine per unit protein is 3–5 times its normal value. Nephrectomy or bilateral obstruction of the ureters has qualitatively the same effect upon serum colloid-pressure as poisoning, although to a less degree. These results are ascribed to the presence in serum of larger protein-aggregates, due either (1) to an increased capillary permeability allowing the passage of small protein "molecules" into the tissues; (2) albuminuria, with passage of the smaller protein particles into the urine; (3) functional changes in the organs responsible for the regulation of blood protein. These results take on an added significance in the light of the recent work of Van Slyke. H. EAGLE

Metabolism of blood glucose in experimental trypanosomiasis. G. ZOTTA AND E. RADACOVICI. *Arch. roumaines path. exptl. microbiol.* **2**, 55(1929); *Rev. hyg. méd. prév.* **53**, 65(1931).—Exptl. studies with guinea pigs in Nagana showed no definite relation between hyperglucemia and the nos. of trypanosomes present in the blood. It is believed that the hyperglucemia in trypanosomiasis is due to a disturbance of the central gluco-regulating mechanism in the body. C. R. FELLERS

Cholesterol content, viscosity and p_H of blood after splenectomy. L. BUGNARD *Compt. rend. soc. biol.* **101**, 546–8(1929); *Physiol. Abstracts* **14**, 661; cf. *C. A.* **24**, 3556.—

The cholesterol content and the viscosity of the blood are increased after splenectomy. The changes begin at once. Temporary suppression of splenic function by clamping the pedicle was practised in dogs. When the clamp has been on for a few min. there is an appreciable increase of viscosity. After prolonged clamping there is no return to normal viscosity. G. G.

Sodium and chlorine of organs in uremia. L. Blum and P. Grabar. *Compt. rend. soc. biol.* **101**, 717–8(1929); *Physiol. Abstracts* **14**, 648.—In uremic conditions there are important modifications of the contents of Na and Cl. Na and Cl in some cases are much increased, especially Cl, as shown by lowering of the quotient Na/Cl. In other cases the diminution of the quotient is marked with a slight increase of Na. In still others the quotient is raised above the normal. The changes are not characteristic, or at least not characteristic of the various states grouped under the title uremia. G. G.

Sodium and chlorine in nephritis with scarcity of salt. L. Blum and P. Grabar. *Compt. rend. soc. biol.* **101**, 718–9(1929); *Physiol. Abstracts* **14**, 648.—In some fatal cases of Bright's disease the Na and Cl contents of different organs are greatly diminished but the quotient Na/Cl is greater than normal. In other cases the loss of Cl is less marked. This loss is pronounced in the myocardium. The least diminution is in the gray matter of the cerebrum. G. G.

Indoxylemia and indoxyluria in a pelvic tumor with compressed ureter. H. Thiers. *Compt. rend soc. biol.* **102**, 91–2(1930); *Physiol. Abstracts* **15**, 171.—In a pelvic tumor with compression of the ureters, progressive uremia, oliguria and alimentary intolerance, the indoxylemia varied with the indoxyluria, both declining as the uremia progressed. The reaction of Obermayer for blood indoxyl is pos. only when indoxyluria is present and in renal impermeability. It does not seem that any important value can be attached to retention of indoxyl in the condition of uremia. G. G.

Relation between alkali reserve and leucocyte index. S. Uchocha. *Compt. rend. soc. biol.* **102**, 354–5(1929); *Physiol. Abstracts* **14**, 551.—Acidosis was produced in dogs and rabbits by the administration of NH_4Cl. This causes, in rabbits, a lowering of the alkali reserve and a displacement to the left of the leucocyte index (Arneth). As the acidosis passes off, the leucocyte index returns to normal. Similar results were obtained in the dog, but with less influence on the alkali reserve. The same phenomena were observed in human beings with affections causing diminution of the alkali reserve. G. G.

Anisotonia in uranium nephritis. E. Pribyl. *Compt. rend. soc. biol.* **102**, 402–4 (1929); *Physiol. Abstracts* **14**, 573.—In 6 rabbits rendered nephritic by the use of U nitrate acidosis and non-protein N of the blood were increased in a parallel manner. In one instance in which a cure was effected, the non-protein N returned to normal but the acidosis persisted. The urinary Ca remained unchanged. The urinary NH_3 was greatly increased, which points to a regulatory function in acid-base equil. The NH_3 of the blood showed no increase. NH_3 is obviously formed in the kidney. G. G.

Permeability of the placenta to the serum antitoxin complex. L. W. Larrier and L. Richard. *Compt. rend. soc. biol.* **102**, 564–6(1929); *Physiol. Abstracts* **15**, 65.—Antitoxins pass through the placenta to the fetus, but heterologous normal serum does not. The antitoxic serum passes slowly, as is shown by complement deviation, but the quantity is appreciable. Anaphylactic sensitization of the fetus can be effected with antitoxic serum. G. G.

Alimentary anaphylaxis and desensitization per os. R. Jahiel. *Compt. rend. soc. biol.* **103**, 59–60(1930); *Physiol. Abstracts* **15**, 196.—In a woman of 21, certain phenomena of anaphylactic nature were observed, which in their course and treatment bring the case into line with lab. expts. on animals. It was found that the exact doses of milk necessary to cause pruritus, urticaria, etc., was more than 5 cc.; accordingly, 5 cc. of milk was administered regularly 1 hr. before giving a bowl of milk which was thus tolerated. Some days after the beginning of this treatment the anaphylactic state still existed, as the taking of a bowl of milk without the preliminary small dose caused urticaria, but ultimately the tolerance of milk was established. G. G.

Potassium in normal and pathological serum. A. Remond and E. Cantegrid. *Compt. rend. soc. biol.* **103**, 63–4(1930); *Physiol. Abstracts* **15**, 153.—Low blood K is found in Parkinson's disease and in diabetes. Markedly high blood K is observed in nephritis but not in proportion to the degree of azotemia. High blood K of less degree than in nephritis accompanies cancer but is independent of the seat and type of growth. The K is normal in amt. in numerous other conditions examd. G. G.

Zinc porphyrinuria. E. Derrien and P. Cristol. *Compt. rend. soc. biol.* **103**, 126–8(1930); *Physiol. Abstracts* **15**, 171.—In the "metallic spectrum" in porphyrinuria

Zn was demonstrated as the cause in certain cases. In the intervals between crises the Zn in the urine amounted to 1 mg. per 24 hrs., whereas during the attacks it was at least 3 times more abundant. The crisis is regarded as probably due to zincopenia, and an indication is provided for treatment with Zn. G. G.

Mode of action of manganese salts in immunization. A. LUMIÈRE AND R. H. GRANGE. *Compt. rend. soc. biol.* **103,** 261–3(1930); *Physiol. Abstracts* **15,** 132.—Injection of Mn salts in the dog caused a marked leucocytosis. It is probable that the increase of immunity produced by this method is due to this leucocytosis. Substances capable of stimulating the leucogenic function should be made use of for immunizing purposes. G. G.

Variations of affinity of hemoglobin for oxygen in hyperthyroidism. G. LITARCZEK, H. AUBERT AND J. COSMULESCO *Compt. rend. soc. biol.* **102,** 1110–1(1930); *Physiol. Abstracts* **15,** 89.—In hyperthyroidism an increase of the const. $1/K$, expressing the affinity of hemoglobin for O, was found. An increase of $1/K$ corresponds to a lower assocn. curve and to a more ample liberation of O to the tissues. The increase is not so accentuated as in anemic subjects. G. G.

The pathology of iron. F. PROESCHER. *J. Lab. Clin. Med.* **13,** 807–18(1928); *Physiol. Abstracts* **13,** 541.—A histological study of blood, of brain and of other tissues in cases of paresis, pernicious anemia and malignant growths was carried out with the Berlin-blue and methyl-green methods of staining. Many speculative suggestions are put forward to account for the distribution of Fe found by this method. G. G.

Ammoniacal output in alkalosis. M. POLONOVSKI, P. BOULANGER AND H. WAREMBOURG. *Compt. rend. soc biol.* **100,** 267–9(1929); *Physiol. Abstracts* **14,** 39; cf. *C. A.* **23,** 4970.—It has not been possible to confirm the views of Janney that increased NH_3 in the urine is anti-acid in function and that excess of $NaHCO_3$ by the mouth annuls the NH_3 eliminated. NH_3 seems to be taken from the blood by the kidney in obedience to a law similar to that governing the selection of urea. It is further confirmed that the NH_3 output does not follow that of total N, and exptl. alkalosis causes reduction of the ammoniacal coeff. which, according to the law of Hasselbalch, should remain const. E. C. K.

Blood creatinine and creatine in pathological states. J. GAVRILA, V. VOIR AND KAMNEANTZU. *Compt. rend. soc. biol.* **100,** 381–3(1929); *Physiol. Abstracts* **14,** 471.—In 15 cardiovascular cases the creatinine varied from 1.3 to 2.14 and creatine from 3.04 to 6.65 mg. %. In 13 cases of diabetes the creatinine varied from 1.33 to 2.5 and creatine from 4.05 to 7.5. mg %. In leucemia creatinine varied from 1.42 to 2.5 and creatine 3.6 to 6.72 mg. %. In 24 cases of chronic nephritis the creatinine varied from 1.33 to 10 and creatine from 3.93 to 17 mg. %. N showed parallel variations. In 7 cases of pulmonary tuberculosis the creatinine varied from 1.26 to 1.66 and creatine from 3.44 to 5.84 mg. %. In tuberculosis, pleurisy and bronchiectasis the normal limits were maintained. E. C. K.

Soap-venom complexes in immunization against cobra venom. M. RENAUD. *Compt. rend. soc. biol.* **103,** 143–4(1930); *Physiol. Abstracts* **15,** 197.—Venom of the cobra mixed with Na oleate or palmitate loses its toxicity. The immunizing power of this mixt. was tested by repeated injection into guinea pigs. In 30% of animals it was distinctly demonstrated. Soap behaves toward venom as it does toward toxin, notwithstanding the remarkable differences of chem. structure between venom and toxin. It annuls the toxic action while leaving the antigenic properties intact. E. C. K.

Pathological variations of protein osmotic pressure and the protein composition of blood serum. CH. ACHARD, A. GRIGAUT AND A. CODOUNIS. *Bull. soc. chim. biol.* **12,** 417–40(1930).—By using the osmometer of Grigaut and Boutroux, greater variations were found in the osmotic pressure of the serum proteins than in the ratio of albumin to globulin. From the study of 4 normal and 56 pathol. subjects very little correlation was found between the values and the condition of disease, except the low total protein in nephritis. The albumin-globulin ratio was found to be of little significance. C G. KING

The iodine content of the thyroid gland accompanying simple and exophthalmic goiter. P. SAINTON AND H. SIMONNET. *Bull. soc. chim. biol.* **12,** 773–6(1930).—The av. I contents from 13 cases of simple goiter and 11 cases of exophthalmic goiter were 0.095 (0.010–0.215) and 0.090 (0.010–0.267)% dry wt., resp. C. G. KING

The absence of tryptophan and histidine as the cause of pernicious anemia. Therapy of the anemias by supplementing the organism with hematogenic amino acids. GEORGE FONTÈS AND LUCIEN THIVOLLE. *Compt. rend.* **191,** 1395–7(1930).—F. and T. argue that the absence of tryptophan and histidine may be regarded as the cause of anemias. Experimentally the administration of the 2 amino acids in cases of leu-

cemic, secondary, splenomegalic and neoplastic anemias produced encouraging results. B. S. LEVINE

The "zoning" phenomenon in complement fixation with cholesterolized alcoholic beef heart extract. Its mechanism and significance. B. S. LEVINE. *J. Infectious Diseases* **48**, 189–202(1931).—L. presents theoretical considerations and exptl. evidence to explain the mechanism and significance of the "zoning" phenomenon occurring in complement fixation employed in the lab. diagnosis of syphilis in which the preliminary incubation is done in the ice box. By "zoning" L. means the occurrence of a stronger fixation of complement in a lesser amt. of suspected serum. He concludes that in the serum of most adults there are various types of immune substances either in the free state or in union with their respective homologous antigens. Upon the addn. of cholesterolized alc. beef heart suspension, the action of which L. proves to be non-specific, interfaces are created at the suspended particles of the colloid. The so-called immune complex concentrates at such interfaces in spherical and spheroid configurations. With the increase in the diln. of the serum, the dispersion of the suspended complexes increases, leading to an increase in the surface area of the sensitized spheres in accordance with the following formula: $S_2/S_1 = \sqrt[3]{n_2/n_1}$, where S_2 = surface area of the suspensoid in the more dil. serum; S_1 = surface areas of the sensitized spheres in the original diln. of the serum; n_2 = the no. of suspended spheres in the more dil. serum; and n_1 = the no. of spheres in the serum of the original diln. In a special case where $n_1 = 1$, the formula becomes $S_2/S_1 = \sqrt[3]{n_2}$. With a ration of the dispersion in the serum of the higher diln. to that of the lower exceeding 8:1 the consumption of the complement by vol., $v/2$, of full strength serum will be greater than the consumption of complement by vol., v, of full strength serum when both are dild. with the saline-antigen suspension to the same final volume. Hence, "zoning" will appear in all serums in which the consumption of complement by the so called "non-specific" antibodies in the first tube of the cold fixation procedure just exceeds, equals or nearly equals one "unit." The significance of the "zoning" phenomenon rests on the fact that it definitely proves the general immunologic rather than the specific leutic nature of complement fixation with cholesterolized alc. beef heart ext. L. concludes that to consider serum specimens manifesting "zoning" "positive for syphilis" is paramount to denoting positive for syphilis specimens showing hemolytic inhibition in a complement fixation procedure where 1.0 or 1.1 unit of complement is considered the "dose." B. S. LEVINE

Chemical investigations in Dercum's disease. IRVINE H. PAGE. *Virchow's Arch. Path. Anat.* **279**, 262–4(1930).—The depot fat of the abdominal cavity and that of the thigh were similar, and likewise normal, in a case of Dercum's disease. Chem findings do not explain why fat is laid down in Dercum's disease. E. R. LONG

Animal ochronosis and porphyry. R. FIKENTSCHER. *Virchow's Arch. Path. Anat.* **279**, 731–9(1931).—Beef kidneys, bone marrow and bone from a case of so-called "animal ochronosis" were examd. for the presence of porphyry. The results were negative in the kidneys and bone marrow and positive in the bone. In bone the substance was detected by direct chem. analysis and spectroscopic examn. of extd. pigment. F. concludes that the ochronosis, or better, osteohemochromatosis of cattle depends, in part at least, on porphyry. E. R. LONG

The glycogen content of the cadaver liver. HANS POPPER AND OSKAR WOZASEK. *Virchow's Arch. Path. Anat* **279**, 819–68(1931).—The total carbohydrate and glycogen content of the liver was detd. in 177 human bodies. Examn. was made as soon as possible after death. Usually the values obtained by chem. detn. of total carbohydrate and histol. estn. of glycogen corresponded. In sudden deaths, in persons previously in good health, the total carbohydrate content of the liver ranged from 1.56 to 6.17% of the moist wt., with considerable amounts of glycogen histologically visible. When death occurred after a wasting disease, the figure ranged from 0.24 to 1.53%, with little or no glycogen demonstrable in sections. In 22 cases of cirrhosis of the liver, where death came gradually, the value for total carbohydrate was 0.38–0.94%. Histologically demonstrable glycogen was relatively high. In 17 diabetics the total carbohydrate was 1.19–8.50%, *i. e.*, significantly higher than in other pathological conditions and equal to, or higher than, in the normal state. Glycogen could always be found, usually in considerable amount. In 11 liver tumor metastases total carbohydrate was 0.28–1.45%; glycogen was histologically not demonstrable. In 26 kidneys the total carbohydrate ranged from 0.28 to 1.64%, the higher values being found in cases of diabetes mellitus. E. R. LONG

A study of the blood urea clearances with relation to diuresis in normal and nephritic animals. ROBERT L. JOHNSTON. *J. Lab. Clin. Med.* **15**, 943–52(1930).—The ability

of the kidneys of the normal and nephritic, fasting animal to clear the blood of urea is correlated with the water-diuresis curve. A simple diuresis test is described for the detn. of the status of renal function. E. R. MAIN

The incidence of lipoids in urine. A report of the micropolariscopic examination of 1470 specimens. ARTHUR T. BRICE, JR. *J. Lab. Clin. Med.* **15**, 953–60(1930).—Lipoid substances were detected in 13.3% of the pathol. urines examd. A high incidence of urine lipoids assocd. with degenerative diseases of the kidneys suggests that pathol. conditions in the gall bladder may be an etiologic factor. E. R. MAIN

The Congo red test with special reference to excretion of the dye in the urine. NELSON W. BAKER AND ALBERT M. SNELL. *J. Lab. Clin. Med.* **16**, 262–70(1930).—The disappearance of more than 60% of intravenously injected Congo red from the blood stream in 1 hr appears to be a sp. test for amyloidosis. The dye is not excreted in the urine in the absence of albuminuria. It is excreted in relatively large amts. in chronic lipoid nephrosis and, in some instances, in nephrosclerosis with albuminuria and in renal amyloidosis. E. R. MAIN

Adrenaline glucemia in disturbances of the liver. G. NANNINI. *Minerva med.* **1930**, II, 874–7.—The glucemic curve was studied after the injection of adrenaline into 20 patients suffering from various hepatic lesions. The results indicate that the glucemic values are useful in the diagnosis of hepatic lesions and also for differentiating various types of icterus. PETER MASUCCI

The function of the liver in cardiopathic cases investigated by means of the amino acid curve. LUIGI ALZONA. *Minerva med.* **1930**, II, 917–23.—The hepatic function in patients with various forms of cardiac disturbances was studied by detg. the amt. o amino acids in the blood after the intravenous injection of glycocoll. A. concludes that the deaminizing action of the liver in cardiopathic cases varies according to the valvular lesion; the relation between compensation and the deaminizing power of the liver is not const.; in aortic lues, glycocoll disappears from the blood with more difficulty; as a general rule, the older the lesion, the more impaired is the hepatic function. PETER MASUCCI

The determining factors of the hypoglucemia in diabetic children. PEDRO B. LANDABURE. *Semana méd.* (Buenos Aires) **1931**, I, 160–4.—In 50% of diabetic children subjected to a diet and insulin treatment, hypoglucemic symptoms develop. This is due to a high variability of the glucemia in children. Even doses of 2 to 5 units may cause the syndrome which is not controlled by the sugar-forming substances in the diet. The symptoms appear at a blood sugar between 0.07 and 0.024%. A direct relation between the sugar level and the severity of the symptoms could not be established. A. E. MEYER

The passage of some normal antibodies from the mother to the fetus. ELISA MORELLI. *Sperimentale* **84**, 431–41(1930).—The bactericidal power against cholera vibrios in the blood of the pregnant guinea pig is not transmitted to the fetus. The hemolytic capacity of rabbit blood decreases during pregnancy and is not present in the new born. The lack of antibodies does not seem to be connected with changes of the complement in the blood. A. E. MEYER

The action of proteins in the growth of grafts of homologous neoplasms. GIOVANNI FAVILLI. *Sperimentale* **84**, 489–504(1930).—Mouse carcinoma and rat sarcoma were transplanted after a previous stimulation of the reticulo-histiocyte system by injection of protein. The growth was stimulated in this case; this is probably due to injuries in the spleen caused by the proteins. A. E. MEYER

Isolation of the toxin of Fraenkel's gas gangrene bacillus. II. ALFRED EBEL. *Biochem. Z.* **229**, 265–8(1930); cf. *C. A.* **24**, 5854.—Culture filtrates acid to litmus were evapd. *in vacuo* and completely pptd. by the addn. of 96% alc. The alc. soln. was then evapd. *in vacuo* to a very small vol. and again pptd. with alc. The alc. soln. of the poison was treated once more as above, until the condensed material dissolves completely in 96% alc. Upon the addn. of abs. alc., however, a thick, inactive ppt. is again produced. The soln. of the poison in the abs. alc. is now put through the same process of purification with abs. alc. until the concentrate completely dissolves in the abs. alc. and gives no ppt. even with an alc. soln. of $Pb(OAc)_2$. The soln. of the poison in abs. alc. is subjected to electrodialysis against distd. water, when only the cathode portion reveals strong activity and an alk. reaction. This portion was greatly concd. *in vacuo* and mixed with 4 vols. of 96% alc.; upon standing in the ice box inactive crystals sep. out. The alc. soln. is again concd. and purified by electrodialysis. The alk. dialyzate is pptd. with Pb acetate, the soln. freed from Pb and once more electrodialyzed. The dialyzate is concd. *in vacuo* and treated with alc. until the residue of the abs. alc. soln. is completely sol. in abs. alc. Pptd. now with ether, the

ether-alc. soln. retains the bulk of the poison. A further attempt is in progress to isolate the poison from this ether-alc. soln. S. MORGULIS

Studies on glucolysis of the blood. I. H. K. BARRENSCHEEN AND KARL HÜBNER. *Biochem. Z.* **229**, 329-42(1930).—An investigation of a number of glucolysis curves shows that the application of the equation of a first order reaction even with Fukushima's corrections for adsorption and diminished enzyme activity does not yield uniform reaction consts., more particularly during the initial stages of glucolysis. Studies on blood from normal fasting persons show that there is a 15–30 min. induction period which can be eliminated under the influence of SO_4 ions. The blood glucolysis is similarly stimulated by PO_4 and AsO_4 ions. The inorg. P during the first hrs. of glucolysis does generally diminish; this is attributed to a process of phosphorylization, the SO_4 ions stimulating this diminution in the P. It is interpreted that SO_4 ions activate the P-esterifying process Previous excessive ingestion of carbohydrate causes the disappearance of the induction time observed in the glucolysis of blood from the fasting subject, and the decrease in inorg. P occurs sooner and to a greater extent. Similarly the addn. of hexosediphosphate (but not of mono-phosphate esters) causes the disappearance of the induction time and accelerates the glucolysis. S. MORGULIS

Disturbances in the mineral regulation mechanism in diseases of cattle. A study of tetany. B. SJOLLEMA AND L. SEEKLES. *Biochem. Z.* **229**, 358-80(1930).—A study of blood serum of cattle suffering from delivery paresis and a "grass tetany" reveals some remarkable changes in the mineral metabolism, particularly in the Mg content, the concn. of Ca ions and of the inorg. P. In the former disease these quantities were on the av. 2.19, 0.44 and 2.16 mg. %; in the latter, 0.46, 1.18 and 4.33 mg. %, resp. The difference between these 2 pathol. states was also manifested in the total Ca content, namely, 4.35 and 6.65 mg. %, resp. In the normal cattle the concns. of Mg, P, Ca^{++} and Ca on the av. were 1.66, 4.57, 1.65 and 9.35 mg. %, resp. A graphic method has been developed for representing the total blood content of Mg, Ca and P in such a way that the normal and pathol. states are spatially sepd. In delivery paresis the ratio Ca/Mg = 2 approaches that (0.9) existing when narcosis is produced through the injection of a Mg salt. In "grass tetany" this ratio is Ca/Mg = 14.6, while in normal cattle it is 5.6, showing that there is actually a condition of excitation. In "grass tetany" the Mg content of the blood varies according to the time of the collection of the sample. If taken at the beginning of an attack of tetany the Mg is low and after the attack it is almost invariably high, possibly because of the strong muscle contraction during the convulsions. The tetany attacks in "grass tetany" occur even when the Ca/P is relatively high, namely 1.5, whereas in parathyroid tetany the attack does not take place unless this ratio is less than 1. In both pathol. conditions, however, the % of diffusible Ca undergoes wide variations Whereas in normal cattle the diffusible Ca constituted 48-66% of the total, it ranged from 25 to 100% during delivery paresis and from 40 to 100% during "grass tetany," but no connection was observed between the change in the % of diffusible Ca and the attacks. The inorg. P of the serum is completely diffusible under all conditions. The diffusible fraction of the Mg varied greatly in the normal and in the sick cattle. In delivery paresis no evidence was found of a relationship between the concns of the Ca^{++}, H^+, HCO_3^- and HPO_4^{--} of the serum. S. MORGULIS

Behavior of blood water during asphyxia. TAKESHI SASO. *J. Biochem.* (Japan) 12, 281-315(1930).—The plasma vol. in acute asphyxia decreases about 14.8%, this being practically independent of the dehydration of the blood. The sp. gr. of the serum is always raised by about 0.3% in acute asphyxia. The dehydration of both blood and serum during acute asphyxia is very small, being on the av. 0.6% for serum and only 0.3% for the whole blood. In prolonged asphyxia, on the contrary, the water content of the serum or blood always increases and there is never any dehydration. The dehydration occurring in acute asphyxia is not extensive enough to account for all the changes in the concn. of the various blood constituents, and the passage into the blood from the tissues must be the chief source from which these increases originate. Particularly in prolonged asphyxia, when there is actual hydremia, the increased concn of different blood constituents is obviously due to migration of substances from the tissues. S. MORGULIS

Comparative study of proteins in blood serum and pathological serosities. CH. ACHARD AND A. ARCAND. *Compt. rend.* **189**, 510-2(1929).—The authors question the fact that the proteins of exudates and transudates come only from blood plasma. Pointing out that the protein content of plasma varies notably in pathol. conditions they compare the protein content of blood serum with that of serous liquids. In 12 cases of pleurisy (10 inflammatory and 2 cardiac) about 50% of protein was found in

the serous liquids while 63–86% was found in the blood serum. The ratios between the proteins of blood plasma and serous liquids (serum/liquid) were 1.25 to 1.76 for the inflammatory cases, and 2 to 2.89 for the cardiac. The ratios for individual proteins were: albumin 1.16 to 2.24 (one exceptional value of 0.91); globulin, 1.14 to 2.23 (2 exceptional values of 0.96 and 4.13); *myxoprotein*, 1.07 to 1.79 in six cases, but 3.53, 5.66, 6.50 and 17.92 in four cases; in the two cardiac cases the values were raised for albumin and globulin, but were discordant for *myxoprotein* (1.07 to 5.66), in two cases exceeding the ratio for globulin in the blood serum but not in the serous liquid. In seven cases of dropsy the values of serum/liquid were 11.13 to 22.96 (one exceptional value of 1.60 in a case of serum rich in protein). The ratios for the individual proteins were: albumin, 3.61 to 46.47; globulin, 1.60 to 40.13; *myxoprotein*, 4.75 to 32.31. The ratios show that there was always much less albumin, globulin and *myxoprotein* in the serous liquids than in the blood serum, but the proportion was much more variable for *myxoprotein*. A. and A. conclude that most of the proteins of serous liquids come from blood plasma, but that this does not exclude the possibility of protein formation in the serous membranes. A. L. RAWLINS

Guanidine-like substances in the blood in experimental yellow fever. G. M. FINDLAY AND E. HINDLE. *Lancet* 1930, II, 678–9.—In exptl. yellow fever in monkeys there is an increase in the blood content of guanidine-like substances, similar to that assocd. with other conditions involving liver necrosis. This increase can be reduced by the administration of Ca lactate, which, however, does not prevent death but does tend to prevent hemorrhages. The method of Pfiffner and Myers was used for detg. the guanidine-like substances. F. B. SEIBERT

Manganese in foodstuffs and its possible relation to cirrhosis of the liver. A. E. BOYCOTT AND G. R. CAMERON. *Lancet* 1930, II, 959.—The method of Bradley (Lindow and Peterson *C. A.* 22, 125) was used for detg. the Mn. Various food products were analyzed and of them cloves, tea, pepper, ginger, coriander, winkles and scallops contained the most Mn. F. B. SEIBERT

Plasma-protein loss with edema but without proteinuria and its bearing on the concept of nephrosis. T. I. BENNETT, E. C. DODDS AND J. D. ROBERTSON. *Lancet* 1930, II, 1006–8.—Massive loss of protein may occur from the blood by routes other than the kidney and edema follows this loss. In such cases no pathol. changes are produced in the kidneys. F. B. SEIBERT

Urea content of the cerebrospinal fluid in status epilepticus. O. R. BINYON AND J. TYLOR FOX. *Lancet* 1930, II, 1233–4.—There was a high urea and glucose content of the cerebrospinal fluid. F. B. SEIBERT

Inflammation. V. The mechanism of fixation by the inflammatory reaction. VALY MENKIN. *J. Exptl. Med.* 53, 171–7(1931); cf. *C. A.* 24, 4833.—Microscopic studies show the presence of a network of fibrin within the tissues and numerous thrombosed lymphatics at the site of inflammation. Pptd. Fe compds., possibly coagulated horse serum or particulate matter caught in this fibrinous reticulum, will disseminate less readily than trypan blue from the site of inflammation. Trypan blue injected at the periphery of an inflamed area fails to enter the site of inflammation. Fixation of foreign substances by the inflammatory reaction is primarily due to mechanical obstruction caused by a network of fibrin and by thrombosed lymphatics at the site of the inflammation. **VI. Fixation of trypan blue in inflamed areas of frogs.** *Ibid* 179–83.—Trypan blue, injected into the circulating blood stream of frogs, accumulates rapidly in an inflamed area; injected directly into the area of inflammation, it is fixed *in situ* and fails to diffuse outward. If the dye is injected at the periphery of an inflamed area, it fails to enter the site of the inflammation. This failure of penetration is caused by the occlusion of lymphatic vessels and the presence of a network of fibrin in the inflamed area. C. J. WEST

Mineral content of pastures research (ASTON) 12. The detection of horse meat as an adulterant in sausage and other studies of the precipitin test (BOLIN) 12.

A. N. RICHARDS

Elimination of quinine in the bile. F. CAUJOLLE. *Bull. soc. chim. biol.* 12, 299–306 (1930).—The presence of quinine in the bile of dogs, after intravenous injection of an isotonic soln. of the neutral sulfate, is demonstrated by observing the fluorescence in

H_2SO_4 when exposed to light from a Hg vapor lamp after passage through a suitable filter. Elimination is more rapid in the urine than in the bile. B. C. A.

Intestinal elimination of iron in the dog. V. Henriquès and A. Roche. *Bull. soc. chim. biol.* **12**, 404–8(1930).—A daily oral administration of Fe (360–1675 mg.) as lactate does not affect elimination by the colon. The intestinal absorption of Fe (detd. by the $TiCl_3$ method) varies with the salt used, and the results do not support the theory of absorption in the small intestine and elimination by the large intestine. B. C. A.

Arrest of the internal secretion of the pancreas during decamethylenediguanidine hypoglucemia. E. Zunz and J. La Barre. *Compt. rend. soc. biol.* **101**, 141–3(1929); cf. *C. A.* **24**, 1149.—Synthalin hypoglucemia is accompanied by a diminution of the secretion of insulin. B. C. A.

Chemistry of overventilation. G. Popoviciu and H. Popescu. *Compt. rend. soc. biol.* **101**, 406–8(1929).—In convulsions caused by over-ventilation there is an increase in serum-Ca and a decrease in the serum-phosphate. The decrease in phosphate is reduced by ergotamine and increased by adrenaline and ephetonine. All these drugs tend to reduce the serum-Ca. B. C. A.

Effect of yohimbine on blood sugar. S. Hanson. *Compt. rend. soc. biol.* **101**, 601–3, 603–5, 605–7(1929).—Yohimbine causes a slight rise in blood sugar; in small doses it suppresses adrenaline hyperglucemia, although with larger doses a rise is observed The increase by yohimbine of the hypoglucemic action of insulin is discussed. B. C. A

Effect of adrenaline on the respiratory metabolism in exophthalmic goiter. I Schill. *Magyar Orvosi Arch.* **30**, 202–9(1929). B. C. A

Influence of electrolytes on the syneresis and clotting of blood. Satya Prakash and N. R. Dhar. *J. Phys. Chem.* **35**, 629–37(1931).—The electrolytes used were KCl, $CaCl_2$, $(NH_4)_2SO_4$, KF, $K_2C_2O_4$, AcONa, $Na_2C_4H_4O_6$, NaOH and Na citrate Each test sample contained 230 cc. of goat blood and was dild. to 250 cc. by the addn. of H_2O and salt soln. The smallest quantity of electrolyte used was 2 cc. of *N* soln. and the largest was 15 cc. of 3 *N* soln. In all cases syneresis decreases with increasing concn. of any one electrolyte. The concns. necessary to suppress syneresis in the clots formed were: KCl 0.12 *N*, $CaCl_2$ 0.0845 *N*, $(NH_4)_2SO_4$ 0.176 *N*, $K_2C_2O_4$ 0.016 *N*, Na citrate 0.016 *N*, KF 0.049 *N*, NaOH 0.039 *N*. If still higher concns. of electrolytes were added the blood was stabilized and no clotting occurred. Stabilizing of blood by fluorides, citrates and oxalates is due not to removal of Ca but to the influence of the anions. Clotting of blood and syneresis are affected by the same forces which affect formation and syneresis of both org. and inorg. gels F. E. Brown

Therapy of spontaneous mouse cancer. Failure of tuberculin, karkinolysin and some inorganic compounds therein. Burton T. Simpson and Millard C. Marsh *Ann. Surgery* **93**, 169–79(1931).—Fifty-six inorg. compds. contg. 33 chem. elements for which there is evidence indicating therapeutic value for transplantable cancer and 4 forms of tuberculin, and 1 ext. of thymus have been found to have no therapeutic action on spontaneous mouse cancer. Rachel Brown

Experimental and clinical studies on the treatment of cancer by dichloroethyl sulfide (mustard gas). Frank E. Adair and Halsey J. Bagg. *Ann. Surgery* **93**, 190–9(1931).—Mustard gas soln. is an effective agent against a localized cancer lesion Rachel Brown

Excretion urography: an experimental investigation of the properties of uroselectan. W. Arthur Mackey. *Glasgow Med. J.* **34**, 9–18(1931).—Uroselectan, the Na salt of 5-iodo-2-keto-1-pyridineacetic acid, is well tolerated by rabbits even when administered in amts. proportionately 10 times the human dose, provided the injection is made slowly Administered rapidly, doses smaller than the max. may be fatal. There is no evidence that the kidneys are injured during the excretion of the concd. soln. of uroselectan The urinary tract of the rabbit may be demonstrated by x-rays during the excretion period. R B

The results of the use of acriflavine hydrochloride in the treatment of undulant fever. D. S. Thurber. *Can. Med. Assoc. J.* **23**, 665–8(1930).—Results from a number of cases suggest the intravenous use of acriflavine materially shortens the course of undulant fever, and prevents the development of an incapacitating arthritis. A. T. Cameron

The danger of indiscriminate iodine prophylaxis. J. F. Reith. *Pharm. Weekblad* **68**, 77–82(1931).—A review of the arguments against the indiscriminate and unsupervised use of iodized salt. A. W. Dox

The silica content of human blood and its alteration by administration of silica.

HEINRICH KRAUT. *Z. physiol. Chem.* **194**, 81–97(1931).—The SiO_2 content of the blood of normal persons varies between 1 and 3% of the sulfate ash, but each individual maintains his SiO_2 value within much narrower limits. The blood of tuberculous subjects contains somewhat more SiO_2 than that of normal persons. Administration of easily absorbed SiO_2 increases the SiO_2 content of the blood by a multiple of the quantity administered. After discontinuing the treatment, several weeks elapse before the SiO_2 content sinks again to normal. Two methods of administration were employed: (1) oral administration of "silistren," a glycol ester of silicic acid, and (2) inhalation of a spray contg. a low mol. silicic acid obtained by hydrolysis of $SiCl_4$ or by treatment of silicates with acids at p_H 2–3. The 2nd method is much more efficient. The av. of 27 cases showed an increase of 1.65% over the normal, while in 1 case it rose to 4.5%. The inhalation expts. show that the increase does not correspond to the quantity administered, but that a mobilization of the SiO_2 of the organism occurs, so that the SiO_2 value of the blood remains altered for a considerable time. Eventually the original value returns. The far greater absorption by inhalation is explained by the fact that the orally administered silistren encounters an unfavorable p_H in the intestine and the bulk of it is there converted into an insol. and difficultly absorbed form. A. W. D.

The fate of ternary chains other than those with three atoms of carbon. V. ZAGAMI. *Ann. physiol. physicochim. biol.* **6**, 365–79(1930).—The subcutaneous administration of AcOH to rabbits causes an increased heat production equal to the energy produced by its complete oxidation. Pentose or ethylene glycol has no such effect. Z. concludes that the metabolism of proteins or of carbohydrates does not necessarily involve the formation of ternary C chains as an intermediate product of metabolism. H. E.

The significance of chemical configuration for the pharmacological effects of adrenaline-like substances. BUN-ICHI HASAMA. *Arch. exptl. Path. Pharmakol.* **153**, 161–86 (1930).—β-Phenethylamine, the basic substance of the adrenaline group, has only slight sympathomimetic action. The introduction of a phenolic OH group in the para position or of an alc. OH group in the β-C of the side chains increases its activity. Interchanging the NH_2 and the OH groups of the β-hydroxy-β-phenethylamine destroys its sympathomimetic action. Increasing the length of the side chains by a Me group decreases the activity by ½. The lability of the adrenaline groups is not necessarily detd by the OH groups of the benzene ring. Replacing a H in the α-C by a second phenyl group destroys the activity upon nerves, but endows the substance with strong muscle-stimulating properties. Oxidizing the secondary alc. to a ketone diminishes the activity. The toxicity of the various members of the group does not parallel the intensity of the sympathomimetic action. H. EAGLE

The kidney action of phlorhizin. Investigations upon frog kidneys. HANS HÄUSLER. *Arch. exptl. Path. Pharmakol.* **153**, 187–213(1930).—With a glucose-free perfusing fluid (Mines soln.) phlorhizin does not cause any change in urine secretion. Its glucuretic action is due (1) to an inhibition of the normal tubular resorption, and (2) to a change in the permeability of the vessel walls for glucose, which allows its passage through the walls of the tubules into the urine. H. EAGLE

Distribution of insulin in the organism following its injection. I. HANS HORSTERS. *Arch. exptl. Path. Pharmakol.* **153**, 214–30(1930). Following its intravenous injection into rabbits, insulin is stored primarily in the liver; within 60 min., however, it appears in the muscles, and gradually increases in quantity, 50% of the total injected being recovered after 3½ hrs. from the muscles. In marked contrast, following subcutaneous injection, the max. storage is reached in 60 min., and then only amounts to 30% of that injected. H. raises the question as to whether the injection of insulin stimulates an endogenous secretion. **II. Relationship between method of nutrition and blood sugar.** *Ibid* 231–43.—In both alimentary and adrenaline hyperglucemia the quantity of insulin which can be extd. from the organs is increased. Animals on a carbohydrate-rich diet also show increased insulin. In such animals, the administration of insulin causes a mobilization of endogenous insulin in the tissues which may exceed the quantity injected. Exogenous insulin is much easier to ext. than endogenous. H. suggests that there are 2 types of insulin: fixed tissue insulin, and free, loosely bound pancreatic insulin. In the diabetic the effective tissue-insulin would be decreased. H. E.

Pharmacological and physiological studies on the sweat centers. IV. The effect of inorganic cations upon the thermal and sweat center in the midbrain. BUN-ICHI HASAMA. *Arch. exptl. Path. Pharmakol.* **153**, 291–308(1930); cf. *C. A.* **24**, 2188.—K, Ba and Na ions injected subcranially into the tuber cinereum cause an increase in temp. and in sweat secretion; Mg and Ca ions are inhibitory. H. EAGLE

The mechanism of the lowering of blood pressure by histamine. MAX HOCHREIN AND ROLLF MEIER. *Arch. exptl. Path. Pharmakol.* **153**, 309–24(1930).—In cattle, dogs

and rabbits very small quantities of histamine cause capillary dilatation, acceleration of circulation, moderate increase of arterial pressure and occasionally also of venous pressure. All these effects can be explained by either a decrease in the total vessel vol., or an increased blood vol. Larger doses cause a transient hypertension, followed by hypotension. Both arteries and veins contract, particularly the latter, causing a diminished flow of blood through the dilated capillaries into the veins. The fall in arterial pressure is therefore due to imperfect filling. There is occasionally an increased liver vol., possibly because of the filling of the hepatic capillaries with blood. A temporary decrease in respiration is followed by an acceleration, possibly on account of the increased pressure in the right auricle. H. EAGLE

The effect of homatropine methonitrate upon gastric secretion. M. TENNENBAUM. *Arch. exptl. Path. Pharmakol.* **153**, 325–30(1930).—Homatropine methonitrate is only $^1/_{10}$ as inhibitory upon gastric secretion by dogs as is atropine. H. EAGLE

The effect of an extract of the posterior lobe of the hypophysis, morphine and caffeine upon the activity of the kidneys. B. SAGER. *Arch. exptl. Path. Pharmakol.* **153**, 331–46(1930). H. EAGLE

The reaction of snake hearts to certain cardiac poisons. OTTO GESSNER. *Arch. exptl. Path. Pharmakol.* **153**, 347–58(1930); cf. *C. A.* **24**, 5374.—The heart of *Tropidonotus natrix* or *Vipera berus* is only $^1/_{1000}$ as sensitive to strophanthin as the frog heart. A qualitatively similar resistance was observed against the whole digitalis group, possibly due to decreased absorption by the cardiac muscle. The symptoms of poisoning, and the effects of cations, particularly Ca and K, are the same as in frog hearts. The stimulating and conducting portions of the snake heart are comparatively more sensitive to digitalis than the contracting portions. Saponin and saponin-like toxins affect snake and frog hearts similarly. The blood of *Tropidonotus natrix* and that of *Vipera berus* are not toxic for the heart of these snakes. H. EAGLE

Treatment of morphinism by insulin and grape sugar. GÜNTHER ANTON AND JOSEF JACOBI. *Klin. Wochschr.* **9**, 1547(1930). H. EAGLE

The differentiation of the total blood sugar into glucose and galactose following the administration of galactose. H. PETOW, H. KOSTERLITZ AND H. N. NAUMANN. *Klin. Wochschr.* **9**, 1549–50(1930).—In normal patients, there is little change in the blood glucose following the administration of galactose The latter disappears from the blood within 2 hrs., reaching a max. of 0.02 0.07% within the first hr. In cases with hepatic damage, the blood galactose may rise as high as 0.145%, and is still demonstrable after 2 hrs. In diabetics, the galactose curve is normal, but there is a surprising increase of blood glucose, which may double its original value. H. E

Effect of insulin upon secretion. PETER F. MEYER. *Klin. Wochschr.* **9**, 1578–81 (1930).—Insulin increases the acidity and usually the quantity of gastric juice within 15–90 min. The blood sugar change is the inverse of this change, reaching min. values when the gastric secretion is at its max. Diabetics who do not become hypoglucemic following insulin show no gastric reaction. In achylia, insulin, like histamine, is ineffective. H EAGLE

The retention of uroselectan in the human body. W. TOURNÉ AND F. DAMM. *Klin. Wochschr.* **9**, 1581–3(1930).—With normal kidney function, there is no demonstrable uroselectan in the blood 4 hrs. after its administration; residual quantities of < 0.5 g. in the blood show partial impairment of kidney damage; > 0.5 g. after 4 hrs. indicates a high degree of kidney damage. H EAGLE

Effect of caffeine in hypoglucemia. LUDWIG POPPER AND SUSANNE JAHODA. *Klin. Wochschr.* **9**, 1585–6(1930).—The symptoms of insulin shock are not related to the hypoglucemia, and can be relieved by caffeine, which does not affect the blood sugar. H. EAGLE

The effect of the administration of bilirubin upon the blood. LUDWIG POPPER. *Klin. Wochschr.* **9**, 1770(1930).—The intravenous injection of 0.05 g. of bilirubin into humans causes a transitory (24 hrs.) increase in hemoglobin without affecting the red cell count. H. EAGLE

Clinical experiences in the treatment of post-encephalitic phenomena with harmine. HEINZ FRANK AND OTTO SCHLESINGER. *Klin. Wochschr.* **9**, 1864–6(1930).—Good results are reported, increased by the simultaneous administration of scopolamine. H. EAGLE

The vascular effect of minute iodine concentrations. GEORG BARKAN AND SALME PRIKK. *Klin. Wochschr.* **9**, 1872(1930).—No definite effect is produced by I_2 in concns. between 1:50,000 and 1:10,000 000 upon the caliber of rabbit ear veins. H. E.

Rhusinic acid, an active constituent of Rhus succedanea, L. KOJIRO TERAUCHI. *Tôhoku J. Exptl. Med.* **16**, 123–56(1930).—The chem. and pharmacol. properties of an

acid isolated from the fruit of *Rhus succedanea* are described in detail. It is primarily cardiotonic, is sympathomimetic and is very toxic for rabbits (lethal dose = 0.0067 g. per kg.). H. EAGLE

Effect of camphor upon the adrenaline output and the blood sugar content in non-anesthetized, non-fasted dogs. KOGORO OIKAWA AND TATSUSABURO INABA. *Tohoku J. Exptl. Med.* **16**, 298–310(1930).—Camphor-olive oil injected subcutaneously into dogs in quantities greater than 1.75 g. per kg. caused increased secretion of adrenaline, hyperglucemia, increased pulse rate and respiration, lasting for as long as 2 hours, with the max. effect in 30–60 min. H. EAGLE

The effect of certain narcotics (urethans) on permeability of living cells to water. BALDUIN LUCKÉ. *Biol. Bull.* **60**, 72–9(1931).—Narcotics in the presence of sea water do not decrease permeability to water beyond the value normally found in the fluid. There is a tendency to reduce permeability to water; narcotics of this type are less effective in this respect than are bivalent cations. This effect, too, depends on the chem. compn of the medium in which the narcotizing compd. is dissolved. F. G. G.

Action of ephedrine on the dog heart (electrocardiograph studies) I. E. COELHO. *Compt. rend. soc. biol.* **99**, 1525–7(1928); *Physiol. Abstracts* **14**, 524.—Synthetic ephedrine, ephetonine (Merck), produces certain modifications in the electrocardiogram of the dog. In small doses it causes bradycardia, sinoauricular and auriculo-ventricular block, ventricular extra systole and increase of the T-wave. In large doses it induces tachycardia and affects the whole conducting system, including Purkinje's fibers. Finally the heart fails in fibrillation. G. G.

Intra-ocular tension and physico-chemical properties of the vitreous humor. E. REDSLOB AND P. REISS. *Compt. rend. soc. biol.* **99**, 1586–8(1928); *Physiol. Abstracts* **14**, 521; cf. *C. A.* **22**, 3422.—Swelling of the vitreous humor depends upon its reaction. Isotonic solns. of HCl and H_3PO_4 were injected into the vitreous humor of rabbits. The tension fell in 30 min., and the normal condition was restored in 30 days. Alk. injections gave less characteristic results. Hypotension often follows the rise. Injection of gelatin causes a marked reduction lasting about 8 days. H_3PO_4 was injected in a case of glaucoma, and caused a marked lowering of tension with relief which lasted a month. The effect of gelatin is due to its action on the isoelec. point of the proteins of the vitreous humor. G. G.

Action of mercurial diuretics on hydremia, chloremia, azotemia and the urinary elimination. I. HATZIEGANU, I. GAVRILA AND BORBIL. *Compt. rend. soc. biol.* **99**, 1813–4 (1928); *Physiol. Abstracts* **14**, 258–9.—Neptal, solyrgan and novasurol given to man on a fixed diet cause identical variations in the blood and urine of subjects with different cardiac and renal affections. Hydremia is increased, reaching a max. 5 hrs. after injection. The Cl of blood is increased but not to the same extent in all cases. The N of the blood is practically unchanged. Intense diuresis occurs on the day of injection. The output of Cl on the day of injection is 2 to 7 times greater than on the day preceding. Urea is only slightly increased but not in all cases. G. G.

Action of insulin and thyroxine on endocrine glands. J. VATRIN AND P. FLORENTIN. *Compt. rend. soc. biol.* **100**, 111–3(1929); *Physiol. Abstracts* **14**, 581.—After injection of insulin the thyroid becomes congested, and colloid degeneration increases in the hypophysis. Thyroxine in increasing doses causes a marked reaction in the pancreas; the islets of Langerhans are multiplied, and new islets are being formed at the expense of exocrine acini. Insulin causes hyperplasic and thyroxine degenerative effects. G. G.

Ergotamine, yohimbine and post-hemorrhagic hyperglucemia. I. I. NITZESCU. *Compt. rend soc biol.* **100**, 386–8(1929); *Physiol Abstracts* **14**, 448.—Ergotamine and yohimbine inhibit the hyperglucemia produced by adrenaline. Hemorrhage causes hyperglucemia with increase of P and Ca. The latter form by hyperglucemia is also inhibited by the drugs mentioned, and it is therefore not due solely to increased glycogenolysis following increased output of adrenaline. G. G.

Action of camphor, hexetone and sodium salicylate on cestodes and Ankylostoma of the dog. S. F. GOMES DA COSTA. *Compt. rend. soc. biol.* **100**, 600–1(1929); *Physiol. Abstracts* **14**, 671.—*d*-Camphor in 3 *M*/1000 soln. is inactive on the *Tenia serrata* of the dog. *l*-Camphor has a stronger effect. Hexetone in 5 *M*/1000 has a strong effect, and causes paralysis in twice this concn. Part of this action is due to the salicylate in which hexetone is dissolved. The action of these reagents on cestodes is somewhat less than on *Ascaris*. On the whole, the action of the camphors on *Ankylostoma* is practically nil. Hexetone is less active on *Ankylostoma* than on *Tenic.* G. G.

Effect of sodium carbonate on polycythemia after muscular exercise. I. I. NITZESCU AND O. MIHALESCU. *Compt. rend. soc. biol.* **100**, 686–9(1929); *Physiol. Abstracts*

14, 456.—Among the metabolites of muscular exercise supposed to stimulate splenic contraction lactic acid occupies a prominent place. Na_2CO_3 injected intravenously opposes this action, which is therefore apparently due to the acid. Psychic excitation and lack of oxyhemoglobin are probably secondary agents. It is important to note that, while the alkali prevents splenic contraction and polycythemia, it does not prevent hyperpnea after exercise. G. G.

Action of chloroform on mammalian plasma and serum. P. BORDET. *Compt. rend. soc. biol.* **100**, 751–3(1929); *Physiol. Abstracts* **14**, 283–4; cf. *C. A.* **24**, 891. —If oxalated rabbit plasma is coagulated under the influence of $CHCl_3$ after several hrs. only traces of thrombin are found in it. $CHCl_3$ coagulation of ordinary plasma yields abundance of thrombin. $CHCl_3$ does not excite the formation of thrombin in the absence of Ca. A serum resulting from normal coagulation rapidly loses its thrombin whereas that arising in presence of $CHCl_3$ maintains activity over long periods. G. G.

Chlorine, bromine and iodine and cardiac excitability. L. DE BORGRAAF. *Compt. rend. soc. biol.* **101**, 167–8(1929); *Physiol. Abstracts* **14**, 359.—Br can completely replace Cl as an anion in the perfusing fluid of the frog heart without causing any important changes in the beat. The irritability, however, is diminished. Iodine used to replace Cl entirely causes distinct changes. The heart is slowed and the irritability diminished. G. G.

Action of sodium glycocholate and sodium taurocholate in Ringer-Locke solution on isolated frog heart. D. MANTE AND S. CIORAPCIU. *Compt. rend. soc. biol.* **101**, 225–6(1929); *Physiol. Abstracts* **14**, 375.—Bradycardia was never observed as a result of the action of a weak soln. of bile salts on the frog heart. Tachycardia was common, except in case of concd soln., which caused, besides bradycardia, intoxication of the myocardium and tendency to arrest the beat. G. G.

The pancreatic function in insulin hypoglucemia. B. A. HOUSSAY, J. T. LEWIS AND V. G. FOGLIA. *Compt. rend. soc. biol* **101**, 239–41(1929); *Physiol. Abstracts* **14**, 380.—After the injection of insulin into (*a*) normal dogs, (*b*) dogs without pancreas and (*c*) dogs with cervical grafted pancreas the glucemic fall is similar in all, but the restoration is slowest in the last-mentioned animals. This fact may be due to the suppression of the extrinsic nervous system, which influences the pancreatic endocrine function and which is stimulated by the hypoglucemia. G. G.

Effect of continued injections of insulin in depancreatized dogs. B. A. HOUSSAY, J. T. LEWIS AND V. G. FOGLIA. *Compt. rend. soc. biol.* **101**, 241–5(1929); *Physiol. Abstracts* **14**, 380.—There is a basal secretion of insulin which increases or diminishes according to the glucemic fluctuation. The amt. can be extd. by injections of insulin into depancreatized dogs. It is necessary in such cases to inject a regular dose of 0.01 unit per kg. per hr. G. G.

Injection of sodium nucleate in dementia precox. H. CLAUDE, P. SCHIFF AND A. DIMOLESCO. *Compt. rend. soc. biol.* **101**, 539(1929); *Physiol. Abstracts* **14**, 672.—A markedly irresponsive condition of the nervous system to injection of nucleate of soda and to other kinds of interference is generally recognized. Yet in cases which show no improvement a profound reaction of the organism is indicated by certain changes in the blood. Leucocytosis is an early occurrence, chiefly affecting mononuclears. It may be exhibited before any signs of fever set in; eosinophils are increased later. The discordance between phys and psychic reactions is very marked in dementia precox. G. G

Influence of the thyroid on reticulo-endothelial blocking. F. GOEBEL. *Compt. rend. soc. biol.* **101**, 596–7(1929); *Physiol. Abstracts* **14**, 658.—Injection of colloidal Ag which blocks the reticulo endothelial system and causes hyperglucemia in normal dogs does not cause hyperglucemia after removal of the thyroid. The hyperglucemia is a function of the glycogen reserve, and it may fail to occur when colloidal Ag is injected into a normal dog after thyroid feeding. Blocking of the reticulo-endothelial system causes no change in the cholesterol content of the blood in the dog after thyroidectomy. G. G.

Secretion and glucemia. E. ZUNZ. *Compt. rend. soc. biol.* **102**, 339–40(1929); *Physiol. Abstracts* **14**, 576; cf. *C. A.* **24**, 413.—Secretin free from hypotensive properties lowers glucemia in the dog, and the degree of this effect is in proportion to that on pancreatic activity. But prepns. of secretin have been found which produce the effect on the pancreatic juice without hypoglucemia. Thus, the two actions are not caused by the same chem. compd. G. G.

Histamine and alkalosis. R. RAFFLIN AND P. SARADJICHVILI. *Compt. rend. soc. biol.* **102**, 559(1929); *Physiol Abstracts* **15**, 39.—Subcutaneous injections of histamine

in epileptics and alcoholics produced a condition of alkalosis due to gastric and urinary secretion of Cl. A max. of alky. was reached 20 min. after the injection. The max. of Cl output by the kidney occurred in 10 min.; then there was a fall due to gastric secretion, followed by a 2nd max. 35 min. after the injection. G. G.

Antagonism of the base tropine (tropanol) and pilocarpine on the submaxillary gland. R. HAZARD. *Compt. rend. soc. biol.* **102**, 574–6(1929); *Physiol. Abstracts* **15**, 59; cf. *C. A.* **24**, 891.—Tropanol checks the secretion of saliva evoked by injection of pilocarpine, and pilocarpine increases the secretion when inhibited by tropanol. G. G.

Changes in toxicity of uranyl nitrate in the rabbit. M. GARNIER AND J. MAREK. *Compt. rend. soc. biol.* **102**, 978–81(1930); *Physiol. Abstracts* **15**, 171.—The authors formerly stated that $UO_2(NO_2)_2$ injected subcutaneously in the rabbit was always fatal in a dose of 0.003 g. per kg. From a series of expts. they show now that the fatal dose varies under certain circumstances between 0.001 and 0.004 g. per kg. A cause of this variation, apart from the breed, is the sex of the animal and the season. Females are more resistant than males, and rabbits injected in the summer are less resistant than in cooler weather. G. G.

Action of ephedrine on the spinal and venous pressures of the dog before and after yohimbinization. M. LOEPER, A. LEMAIRE AND J. PATEL. *Compt. rend. soc. biol.* **102**, 989–91(1930); *Physiol. Abstracts* **15**, 191–2.—In the cholalosed dog the intravenous injection of 5 mg. of chlorate of ephedrine causes a prolonged rise of blood pressure in the carotid artery. In the yohimbinized dog the carotid rise of pressure is suppressed. Ephedrine acts on the meningeal pressure independently of the arterial system. Its action is the opposite of that of adrenaline, which augments the meningeal pressure even after yohimbinization. G. G.

Cholagog action of neptal. E. CHABROL, R. CHARONNAT, M. MAXIMIN, J. PORIN AND BOCQUENTIN. *Compt. rend. soc. biol.* **102**, 991–2(1930); *Physiol. Abstracts* **15**, 169; cf. *C. A.* **25**, 352.—Increasing the mol. wt. of cholagog aromatic acids by substitution increases their effect on the flow of bile. The introduction of Hg into the formula of Na salicylate is effected in neptal. In doses of 2 to 4 cc. it doubles the amt. of bile; in 1 expt. the bile was quadrupled. The Hg *per se* does not affect the action. There is a certain parallelism between the cholagog and diuretic action of neptal. A diuretic like $CaCl_2$, on the other hand, has an inhibitory action on the secretion of bile. G. G.

Influence of the non-saponifiable substance of ox spleen on anemia of the rabbit. C. SOULA, J. TAPIE AND J. FAU. *Compt. rend. soc. biol.* **102**, 1022–3(1930); *Physiol. Abstracts* **15**, 154.—Bled rabbits require 10 to 20 days for the regeneration of the erythrocytes. A rabbit which receives 1 g. of cholesterol daily requires 14 days for this result. Given a daily dose of 1 g. of non-saponifiable substance (X), the rabbit needs but 7 days for the regeneration. G. G.

Study of *p*-aminobenzoate of *N*-diethylleucinol (panthesin). A. ROIG. *Compt. rend. soc. biol.* **102**, 1043–4(1930); *Physiol. Abstracts* **15**, 192.—The formula of panthesin has the same aromatic nucleus as novocaine, $NH_2COOCH_3CH_2N(C_2H_5)_2$. It may be sterilized by boiling. It does not inhibit the action of adrenaline on the rabbit ear. Anesthesia of the cornea with a 2 % soln. of panthesin lasts 58 min., as against 35 for cocaine. The relative toxicity of panthesin, *i. e.*, the ratio of toxicity to anesthetic power, is 2 or 3 times less than that of novocaine. The abs. toxicity of panthesin is greater. G. G.

Cholagog action of certain phenolic acids. M. MAXIMIN AND A. BOCQUENTIN. *Compt. rend. soc. biol.* **103**, 3–5(1930); *Physiol. Abstracts* **15**, 168–9.—Sodium benzoate is inactive toward biliary secretion in the dog in doses of 1 g. per 20 kg. The salicylate gives inconstant results. The *m*-hydroxybenzoate has a strong cholagog action. The diphenol acids, catechuic and caffeic, greatly increase the output of bile with increased wt. of solid ext. *p*-Hydrxoybenzoate is practically without effect. It seems that the position of the *m*-hydroxyl group favors the development of cholagog properties. Vanillic acid, in which the OH in the meta position is replaced by OCH_3, has a very marked cholagog action. Though the phenol function intervenes in the effectiveness of the compd., it is not in itself a sufficient factor. The role of the carboxyl group, as previously described, is further insisted on. G. G.

Action of insulin in tissue culture. E. FRIEDHEIM AND L. ROUKHELMAN. *Compt. rend. soc. biol.* **103**, 10–2(1930); *Physiol. Abstracts* **15**, 173.—Insulin acting directly on mesenchymatous cells in artificial culture is without influence on the formation of glycogen, and, far from increasing the consumption of sugar, it diminishes this consumption. The diminution runs parallel with a disturbing influence on growth *in vitro*. G. G.

Action of dinitro-α-naphthol on the pigeon. P. V. UYTVANCK. *Compt. rend. soc. biol.* **103**, 29–31(1930); *Physiol. Abstracts* **15**, 193.—The pigeon after injection of dinitro-α-naphthol exhibits polypnea; 12 min. later the rectal temp. rises and reaches 46.5° in 18 min. Peripheral vasodilatation, hyperglucemia and diminution of muscular and hepatic glycogen accompany the hyperthermia. The phosphates of blood and muscle are increased. The Ca content of blood does not change. The hyperthermic effects of dinitro-α-naphthol are not suppressed by exposure of the reagent to the rays of a Hg-vapor lamp. G. G.

Action of calcium and potassium on the isolated heart. R. KIRSCH AND H. FRÉDERICQ. *Compt. rend. soc. biol.* **103**, 34–6(1930); *Physiol. Abstracts* **15**, 157.—The chronaxie of the isolated heart of the tortoise is lengthened by an excess of Ca or a deficiency of K. It is diminished in the reverse conditions. If the perfusion with the modified Ringer soln. contg. excess Ca or deficient K be prolonged, then the chronaxie slowly returns to its original normal value. A fresh perfusion now with normal Ringer soln. causes a new variation of the chronaxie in the opposite direction to the first change. G. G.

Karyokinetic action of arsenious acid and alkalosis. M. ROCMANS. *Compt. rend. soc. biol.* **103**, 42–3(1930); *Physiol. Abstracts* **15**, 193–4.—In the guinea pig and dog increased multiplication of the cells in the lymphoid organs occasioned by H_3AsO_3 runs concurrently with a wave of alkalosis. The soly. of the Ca ion is diminished, and this effect is proportional to the dose of H_3AsO_3. The results obtained with H_3AsO_3 correspond with those obtained in peptone shock. The curves of cellular division and alkalosis run parallel. In the dog the normal p_H of 7.42 rises to 7.52, and that of the guinea pig rises from 7.29 to 7.42. The acid-base-regulating mechanism does not alter, for the variations of $NaHCO_3$ and H_2CO_3 are mutually balanced. G. G.

Arterial tension and leucocytes. Action of acetylcholine. L. JUNG AND P. COLLET. *Compt. rend. soc. biol.* **103**, 79–81(1930); *Physiol. Abstracts* **15**, 158.—The lowering of arterial pressure caused by injection of acetylcholine in dogs is accompanied by leucopenia. A return to a normal leucocyte count accompanies the restoration to the normal of arterial pressure, but it is slower than the rise of pressure. G. G.

Latent period of fluoride intoxication. H. CRISTIANI. *Compt. rend. soc. biol.* **103**, 292–4(1930); *Physiol. Abstracts* **15**, 126.—The bones of animals from districts where there are no factories emitting F contain very small quantities of this element in their compn., less than 0.05%. The bones of animals from the neighborhood of Al works contain 0.379%. Therefore, in regions where F is present, even in min. quantity, there is a condition of latent fluorosis in the cattle. G. G.

Strychnine-soap complexes. L. VELLUZ. *Compt. rend. soc. biol.* **103**, 302–3 (1930); *Physiol. Abstracts* **15**, 124.—Soaps tend to neutralize the toxicity of alkaloids but to a less extent than that of toxins. A mixture of oleate of Na and strychnine, boiled for 15 min. on a water bath, may be injected into a guinea pig in 4 times the fatal dose of strychnine without harmful effect. Increase of the amt. leads to the typical symptoms. Repeated injections of the complex during a period of 2 months did not produce any immunity either to pure strychnine or to the complex, and it is obvious that immunization against crystalloid poisons cannot be effected by conferring colloidal characters on them. G. G.

Suprarenal capsules in hyperglucemia produced by decamethylenediguanidine. X. CHAHOVITCH. *Compt. rend. soc. biol.* **103**, 328–30(1930); *Physiol. Abstracts* **15**, 117.—Synthalin produces hyperglucemia in the rabbit by its action on the suprarenal capsules. Bilateral extirpation of the capsules prevents the hyperglucemia following injection of synthalin; extirpation of both suprarenal glands does not *per se* cause variations in the amt. of free sugar in the blood. G. G.

Vascular effects of aconite. H. EKERFORS. *Compt. rend. soc. biol.* **103**, 443–5 (1930); *Physiol. Abstracts* **15**, 124.—Aconitine exerts a double action on blood vessels—constrictor in small doses and vasodilator in large doses. The latter is the more common effect, the first being sometimes doubtful. Atropine does not inhibit the action. Aconitine inhibits the constrictor action of $BaCl_2$, and therefore may be supposed to act on the muscle. G. G.

Alteration of the thyroid gland in fluoride intoxication. H. CRISTIANI. *Compt. rend. soc. biol.* **103**, 554–6(1930); *Physiol. Abstracts* **15**, 193.—Guinea pigs were given fluorides in small doses over long periods and their thyroid glands compared with those of controls. In the glands of the former, lesions were common and marked. The animals died after an av. duration of 53 days. G. G.

Macroscopic alterations of the hypophysis in fluoride intoxication. H. CRISTIANI. *Compt. rend. soc. biol.* **103**, 556–7(1930); *Physiol. Abstracts* **15**, 193.—Chronic poisoning

with fluorides causes diminution of vol. of the hypophysis, which becomes flat in appearance. The thickness in the guinea pig is reduced from about 2.25 to 1.7 mm. G. G.

Immediate hyperglucemia with use of insulin. F. RATHERY, R. KOURILSKY AND (MLLE.) Y. LAURENT. *Compt. rend. soc. biol.* **103**, 563–4(1930); *Physiol. Abstracts* **15**, 173.—Injection of insulin in the normal dog causes an immediate rise of the blood sugar, which is transient; it is followed quickly by a fall. This hyperglucemia is not const., but it is frequent. The phenomenon seems to be independent of the nature of the insulin employed, the dose and the path of injection. G. G.

Insulin hyperglucemia in different vascular regions. F. RATHERY, R. KOURILSKY AND (MLLE.) Y. LAURENT. *Compt. rend. soc. biol.* **103**, 565–6(1930); *Physiol. Abstracts* **15**, 173.—The hyperglucemia immediately following the injection of insulin in the normal dog is more marked in certain parts than in others. It is especially pronounced in the hepatic circulation. There is increased discharge of sugar into the hepatic vein and a notable increase of portal blood sugar. G. G.

Cardiovascular effects of choline derivatives administered by the digestive tract. M. VILLARET, L. JUSTIN-BESANÇON AND R. CACHERA. *Compt. rend. soc. biol.* **103**, 583–4(1930); *Physiol. Abstracts* **15**, 190.—Methylacetylcholine introduced directly into an exposed loop of intestine of the dog causes a fall of blood pressure which is maximal in 1 min. Absorption is extremely rapid. The arterial fall of pressure is very prolonged. The heart is scarcely affected, the fall being due to dilatation of the arterioles. Bromocholine used in the same way causes a fall of pressure which is less marked, but bradycardia sets in with respiratory trouble. The animal dies in 50 min. from a dose of 66 mg. per kg. G. G.

Utilization of pentoses by the animal organism. Action of intravenous injection of pentose on lactose secretion. I. I. NITZESCU AND M. BENETATO. *Compt. rend. soc. biol.* **103**, 1119–22(1930); *Physiol. Abstracts* **15**, 119–20.—After the intravenous injection of pentose the amt. of sugar in the milk is increased. Injection of sucrose causes no change in the output of lactose. The lactose-forming power of rhamnose is not as great as that of glucose, but it is equal to that of galactose. G. G.

Acute mercury poisoning, its treatment and alterations in chlorine, water, nitrogen and acid-base relations during its course. A. LANDAU, J. GLASS AND I. BEILES. *Wiener Arch. inn. Med* 20, 31[illegible]1930).—Acute Hg poisoning with Hg oxycyanate was treated by Bi thera[illegible]dministration, after the period of anuria had passed, of NaCl by mouth [illegible]nd subcutaneous injections of physiol. NaCl soln. A chem. study w[illegible]e blood and urine during the 5 definite stages of the poisoning. During [illegible]st period of anuria there was a retention of water without edema, a marked chloropenia of the plasma and blood corpuscles, a constantly increasing azotemia and a lowering of the alkali reserve, forming a complex which is typical for severe Hg poisoning. The chloropenia is probably due to loss of Cl in vomiting and diarrhea, as in mild cases without these symptoms the chloremia remains normal. The azotemia is very marked; it depends in part on the anuria and on a toxic breaking down of the cell proteins. There is a retention of urea, uric acid, creatinine and other N-contg. compds. The azotemia continued to increase for a time after the administration of NaCl had begun. Administration of NaCl at later stages did not increase the azotemia. Usually in acidosis the Cl index of the blood corpuscles rises from increase in Cl content in the corpuscles. Here, however, there is a marked decrease in alkali reserve without a shifting of the NaCl from plasma to blood corpuscles. In spite of a decreased alkali reserve the urine remained alk. Hyperventilation of the lung from toxic stimulation of the respiratory center by Hg or from toxic split products from cellular proteins, and the lowering of the CO_2 tension in the alveolar air bring about a decrease in alkali reserve of the plasma with excretion of basic substances by the kidneys. HARRIET F. HOLMES

Lymphadenoma produced by injection of coal tar. L. MERCIER. *Compt. rend. soc. biol.* **103**, 125–6(1930); *Physiol. Abstracts* **15**, 198.—Injection of coal tar in olive oil into the peritoneal cavity of the mouse caused generalized hypertrophy of the lymphatic glands, and splenic and pulmonary nodules. In some of the descendants of an animal thus treated lymphadenoma appeared spontaneously. Injection of coal tar into the progeny of sensitized animals caused a rapid appearance of lymphoid growths with an increase in the no. of pos. results. E. C. K.

Reaction of thyroid gland to hypophyseal extract. M. ARON. *Compt. rend. soc. biol.* **103**, 145–7(1930); *Physiol. Abstracts* **15**, 180.—Details are given of the histological changes which occur in the thyroid gland as a result of hypophyseal injection in the guinea pig. The vesicles become empty and the epithelial cells are enlarged. The

evidence of marked activity is more easily observed and less equivocal in the thyroid than in any other gland. E. C. K.

Blood-vessel wall changes produced by vigantol and their regression in animals. ALICE SCHIFF. *Arch. Path. Anat.* (Virchow's) **278,** 62–83(1930).—Feeding vigantol (com. irradiated ergosterol) to cats and rabbits in daily doses of 2–4 mg. for 1–3 months resulted in changes in the media of the arteries. The changes included degeneration, proliferation and calcification. Regression of the lesions could not be definitely established; on the other hand, there was some evidence of subsequent progression E. R. LONG

Initial stages of vigantol injury in rabbits. ERNST LAAS. *Arch. Path. Anat.* (Virchow's) **278,** 346–64(1930).—Single doses of 30 mg. vigantol per kg. animal weight produced in rabbits the following changes: calcification in the media of arteries, beginning in the elastic fibers without a recognizable pre-stage, and passing in the aorta from a localized nodular medial necrosis to a more diffuse degeneration; secondly, calcification in various organs, dependent in turn upon degeneration caused by injury to the vessels concerned in the local blood supply. E. R. LONG

Sectioning of the splanchnic nerve and the effect of cholic acid on the creatinine excretion. AIJIRO TAKU. *J. Biochem.* (Japan) **12,** 371 81(1930). —Subcutaneous injection of cholic acid causes a diminution in the creatinine excretion of the rabbit, but this effect disappears after sectioning of the splanchnic nerve. The hypoglucemic influence of cholic acid is likewise removed by sectioning of the splanchnic. All of this indicates that cholic acid exerts its action not peripherally but centrally. S. MORGULIS

Influence of hyperglucemia and of extirpation of the adrenal bodies on the amylolytic power of saliva and blood. TULLIO GAYDA. *Arch. ital. biol.* **84,** 55 66(1930). —See *C. A.* **25,** 328, 338. S. MORGULIS

Behavior and action of organic sulfur compounds in the organism of the dog. I. Action and fate of thiophene in the metabolism of the dog. ANAST. A. CHRISTOMANOS. *Biochem. Z.* **229,** 248 54(1930).—Thiophene is detd. colorimetrically as follows: To each of 2 test tubes are added 5 cc. concd H_2SO_4 and 2 drops of satd. $CuSO_4$ soln., then 0.05 cc. *N* lactic acid. This is thoroughly mixed and heated in boiling water exactly 3 min. After cooling to about 10° a known amt. of thiophene in alc. soln. is added to one and the unknown soln to the other test tube; this is mixed and left at room temp. for 10 min. when a color from rose to deep red develops, depending upon the concn. of the thiophene The colors should be matched quickly in a colorimeter, and the results calcd. by the formula $C = C_1 + S_1/S$, where C_1 = concn. of known soln., S_1 and S are the colorimeter readings of the known and unknown solns. As little as 0.013 mg. still gives a recognizable color. When fed to dogs 5.7- 12.2% of the thiophene are excreted in the urine as a conjugated product and part is assumed to change to CH_3-CH_2SH in the intermediate metabolism. Thiophene does not depress the total N metabolism Thiophene causes a characteristic ataxy reaction in the dog. S. M.

Influence of different foods on the amount of unsaturated fatty acids with four double bonds in the blood. N. BEREND. *Biochem. Z.* **229,** 323 8(1930).—The amt. of fatty acids with 4 double bonds in blood increases, after a preliminary drop, following the ingestion of fat. This preliminary decrease does not occur if carbohydrate is fed together with the fat. Carbohydrate or protein alone has no effect. S. M.

Assimilability and toxicity of racemic lactic acid. OTTO FÜRTH AND PAUL ENGEL. *Biochem. Z.* **229,** 381–96(1930).—The ingestion of fermentation lactic acid causes in man the loss of 20–30% in the urine. The lactic acid is detd. in human urine by pptg. the urine with phosphotungstic acid and removing from the filtrate the glucide-like substances by pptn. with $Ca(OH)_2$ and $CuSO_4$ In rabbit urine lactic acid cannot be so detd.; the long and difficult preliminary extn. with ether in a Lindt liquid extracter is necessary. For the rabbit lactic acid administered orally proved much more toxic than previously supposed. Although subcutaneously as much as 2.8–3.6 g. per kg. can be injected without any obvious harm, rabbits died when fed 1.6 g. and even as low as 0.6 g. lactic acid per kg., also when that quantity was given over a period of 3 days. For mice the lethal dose for subcutaneous injections of the Na lactate was 2–4 g. per kg. Rats, on the contrary, can withstand prolonged administration of 2 g. or more per kg. without any ill effects. The high toxicity of the ingested *l*-lactic acid for rabbits and its poor assimilability also in man throw doubt upon its value as a food substance. The use of small quantities of lactic acid in lemonades, fruit juices or confectionary is probably harmless. Alkalosis induced by $NaHCO_3$ did not alter the effect of lactic acid in rabbits and mice. Nor was the utilization of the lactic acid by the rabbit materially altered by adrenaline, phlorhizin or loading with sugar. Mild

P intoxication caused in rabbits a large loss of lactic acid, followed, however, by increased retention when the intoxication passed off. *In vitro* expts. on the catalytic oxidation of lactic acid on C surfaces fail to reveal any difference between the *d*- and *l*-acid, as is observed in physiol. expts. S. MORGULIS

Does adrenaline exert a direct action on the base of the mid-brain? R. H. KAHN AND E. RINDT. *Endokrinologie* **8**, 1–4(1931).—Following the application of a 1:1000 adrenaline soln. to the surface of the base of the mid-brain there is no evidence of a sympathetic stimulation of end organs or of any injury. This indicates that the direct application of adrenaline to nerve tissue is without effect On the contrary, a strong rise in blood pressure results promptly from the faradic stimulation of the base of the mid-brain. S. MORGULIS

Effect of alkaline extracts of the anterior lobe of the hypophysis on the genitalia of female rats. M. REISS, H. SELYE AND J. BÁLINT. *Endokrinologie* **8**, 15–22(1931).—Alk. exts. from the anterior hypophysis exert an inhibiting effect on the hormone prepd. from the urines of pregnant women. This inhibiting action was especially manifested on the epithelium of the uterus. The striking changes produced by the injection of the sex hormone were absent if this was accompanied by an injection of the alk. ext. The uterus hypertrophy does not occur in animals treated with both exts. and the great hypertrophy of the ovary likewise fails to develop. S. MORGULIS

Studies on relation of chemical constitution and biological action: amyostatic poisons. TAKAOKI SASAKI AND ICHIRO OTSUKA. *J. Biochem.* (Japan) **12**, 429–58 (1930).—Synthetic products made from aminophenylalanine with glycine anhydride possess very interesting biol. actions. These compds., which are the HCl salts of 3-aminohydrocarbostyrils (3-Astyl), act specifically upon the brain stem and cause, in rabbits given subcutaneous injections, disorganization of the myostatic and statokinetic responses resembling the decerebrate rigidity or the akinetic-rigidity syndrome observed in human pathology. The amyostatic action of local anesthetics like novocaine, tutocaine and acoine is similar to that of the 3-Astyl and its derivs., which also seem to have local anesthesia effects. The original must be consulted for a detailed account of the chem. prepn. of these various astyl compds. and their biol. effects. S. MORGULIS

The cause of the diminished effect of the vagus on the heart under insulin. C. E. RÄIHÄ AND P. MALM. *Skand. Arch. Physiol.* **61**, 64–70(1931).—The diminished chronotropic effect of vagus stimulation upon the heart under the influence of insulin is attributable to a lowered sensitivity of the heart. There is some evidence to show that the depressing effect of the insulin on the response to vagus stimulation is associated with an increased K content of the heart. S. MORGULIS

Copper studies. C. G. SANTESSON. *Skand. Arch. Physiol.* **61**, 79–112(1931).—Liver injury from Cu intoxication may arise in a variety of ways. In some instances of acute intoxication or intoxication for a long period with very large doses the blood is the seat of primary injury. Icterus with hematuria and hemoglobinuria, even hemorrhagic nephritis follow, and sometimes there is also evidence of methemoglobin formation. The disruption of red cells occasionally produces thrombosis of the liver blood capillaries which lead secondarily to necrosis of the parenchyma. However, the liver injury may also result from an altogether different cause. In the author's expts. with $CuSO_4$ the primary change in the liver was a strong capillary hyperemia with extensive bleeding which disrupted the liver parenchyma. The clotting of the blood takes place readily, leading to capillary thrombosis and thus to necrosis without primary blood alterations. The hyperemia is due to dilatation of the finest blood vessels and is common in all metal intoxication (Hg, Bi, Cu and especially As). The bleeding, at least in the case of As and P, results from injury of the vessel wall. S. never found icterus or cirrhosis of the liver, and thinks that possibly rabbits are not subject to icterus. A round cell infiltration was observed which might possibly have been an early stage of cirrhosis. The hyperemia from Cu intoxication extends also to the lung and frequently causes hemorrhage or pneumonia. Although intestinal changes have frequently been described, S. found little evidence in his expts. Likewise, the kidney was only slightly affected, although occasionally a little albumin appeared in the urine but never any bile pigment. Generally the intoxication with Cu or Bi has similar effects, but the former acts more upon the liver, whereas the latter acts on the large intestine and cecum and on the kidneys. S. MORGULIS

Toxic action of dictamnin. A. OGATA. *J. Pharm. Soc. Japan* **50**, 1124–33(1930).—Thoms (*C. A.* **17**, 2583) previously isolated dictamnin (I) from *Dictamnus albus* and studied its toxic action. O. repeated the study of the toxic action of I and found a slightly different toxic action. F. I. NAKAMURA

The action of formaldehyde on neuro-muscular excitability. D. BENNATI AND E.

HERZFELD. *Compt. rend.* 190, 1522–5(1930).—The injection of 0.1 cc. of 2% CH_2O in saline into the lymph sac of a 35 g. frog produced no important changes in the chronaxia or rheobase of the sciatic nerve-gastrocnemius. The injection of 0.5 cc. of the same soln. caused loss of excitability apart from an appreciable modification of the 2 characteristics of this excitability. Av. protocols are included. T. H. RIDER

Physiological action of aminomethyl-(3,4-dihydroxyphenyl)-carbinol. RAYMOND-HAMET. *Compt. rend.* 191, 869–71(1930); cf. Barger and Dale, *C. A.* 5, 109.—*Aminomethyl-(3,4-dihydroxyphenyl)-carbinol* (*artérénol*) (I) when injected prior to *d,l-adrenaline-HCl* (II) causes a greater hypertensive effect than the later injection of an equiv. dose of II. However, when II is injected it produces a greater hypertensive effect than a later injection of I. Loup (*C. A.* 7, 4016) has shown that the hypertensive effect diminishes with repeated equal doses of II or other like substances. The action of I proves a little greater than that of II; therefore, the mechanism of the action must be different. In a dog with a sufficient prior dose of *yohimbine* (III), to reverse the action of II, I still causes hypertension, accompanied, however, by renal dilation, whereas I administered without a prior dose of III causes renal constriction. The action of I is, therefore, similar to that of *ephedrine* (IV) (cf. R.-H. *C. A.* 22, 271). However, while strong doses of IV are hypotensive, fatal doses of I are still hypertensive. Similar to IV and contrary to II; the effects of I are not augmented by cocaine. T. H. R.

The chemistry of anesthesia. WILDER D. BANCROFT AND GEORGE H. RICHTER. *J. Phys. Chem.* 35, 215–68(1931).—All types of anesthesia are considered explained satisfactorily by the theories of Binz and of Claude Bernard, that the reversible coagulation of the colloids of the sensory nerves produces anesthesia. The material offered by this paper, however, is limited to a discussion of general anesthesia, local anesthesia not being specifically included. A cursory criticism of other theories is followed by the development of the Binz-Bernard theory, and a discussion of the 3 basic criticisms directed against it, namely: (*a*) The concns. at which narcotics are active are much less than that required to flocculate the cell colloids. (*b*) Coagulation of the cell colloids represents the toxic effect of a narcotic and is irreversible, whereas narcosis is a reversible phenomenon. (*c*) The cases in which the dispersion of the colloids is decreased by narcotics are explained as being only apparent. In answer to (*a*) B. and R. call attention to the fact that the presence of electrolytes makes possible the flocculation of protein sols with a low concn. of EtOH, and the assumption that the colloidal systems of the cell may be so sensitized in life that a small quantity of a narcotic will flocculate them. (*b*) and (*c*) are answered by the fact that with sensitized protein sols reversible flocculation with low concns. of narcotics was accomplished *in vitro*, and that reversible flocculation was demonstrated in yeast cells. Facts which cannot be explained by other theories but which can be explained by the Binz-Bernard theory are stressed. The stimulation of general protoplasmic irritability produced by low concns. of narcotics is explained as dependent upon the decreased stability of the colloids caused by these low concns. while narcosis is caused by higher concns. Attention is called to the fact that typical stimulants, such as caffeine and strychnine, behave as narcotics in high concn. The stimulating after-effect of narcotics is explained as due to the same colloidal state, passed through again in the process of peptization. Anesthesia caused by water, salts, heat, cold, or elec. or mech. means may also be explained as due to the effect on the colloidal state of protoplasm. The conclusion is reached that there is no relation between chem. structure and physiol. action on the grounds that structure merely dets. the phys. properties, which in turn, together with concn., govern the physiol. action. All drugs are assumed to stimulate in some low concn. and to depress in higher concns. Synergism is explained as follows: A small concn. of a drug is adsorbed entirely upon the principal substrate. The addn. of a synergistic drug which is adsorbed upon the same substrate displaces a certain amt. of its predecessor which then affects the secondary substrates in the same manner as would a higher original concn. Antagonism would occur when the colloids of a cell are reversibly coagulated and the agent that caused the flocculation is displaced by a substance of weaker flocculation capacity for the given concn., in which case the bio-colloids will again be peptized by the electrolytes. NaBr and antipyrine, which have a quieting effect on the nerves, produce a lowered irritability following upon increased dispersion of the colloids. Narcotizing agents are divided into 2 groups: direct narcotics, which coagulate the cell colloids by direct action (Et_2O, $CHCl_3$, EtOH) and indirect agents which interfere with some normal function of the cell, such as oxidation, and the coagulation is produced by the accumulated waste products (NO_2, C_2H_2, HCN). T. H. RIDER

Investigation into the distribution of lead in the organism on basis of a photographic (radiochemical) method. SVEND LOMHOLT. *J. Pharmacol.* 40, 235–45(1930).—A

soln. of $PbCl_2$ contg. a small amt. of radium D was injected into mice and subsequently sections of the various organs, or the entire animal, were prepd. and placed on photographic plates. When the plates were later developed the presence of the radioactive substance could be seen. Pictures showed that Pb is deposited in greatest amt. in the liver, in the cortex of the kidney, and in osseous tissue. Very little was found in the brain. C. RIEGEL

The electrocardiogram of non-anesthetized dogs as modified by the intravenous injection of pitressin, atropine sulfate and vagus section. CHARLES M. GRUBER AND WM. B. KOUNTZ. *J. Pharmacol.* **40**, 253–73(1930); cf. *C. A.* **25**, 745.—The following cardiac changes were noted: (1) a brief period of slowing, (2) a period of acceleration, (3) a prolonged period of slowing. During the latter phase the electrocardiogram showed shifting pacemaker, prolongation of auriculo-ventricular conduction time, sino-auricular block, partial auriculo-ventricular block, extra systoles, high T-waves, high branching T waves and bigeminal pulse. After atropine or vagus section, the same changes were noted. C. R.

A study of the effect of morphine upon the respiratory center. A. H. MALONEY AND A. L. TATUM. *J. Pharmacol.* **40**, 291–304(1930).—Depression of the respiratory mechanism is more marked after neonal, phenobarbital, or (to a less degree) amytal and ethyl-α-methylbutylbarbituric acid, than after urethan, chloral hydrate or avertine. From observations on stimulation of the central end of the cut sciatic nerve, stimulation of the intact skin and the effect of increased or decreased intrapulmonic pressure on respiration after morphine in rabbits it is concluded that morphine reduces the responsiveness of the center to acceleratory afferent nervous impulses and to CO_2, but increases the effectiveness of inhibitory vagal impulses. C. R.

Iodine prophylaxis and endemic goiter. A. T. CAMERON. *Can. Pub. Health J.* **21**, 495–506, 541–8(1930).—An extensive discussion and review of the literature on the distribution of I in nature and its correlation with thyroid diseases, particularly simple endemic goiter. A close relationship between deficiency of I in the diet and simple goiter is indicated. Other possible causes of endemic goiter are discussed. There is strong evidence that in certain regions a water-borne infection is a factor, but this probably acts through an effect on I metabolism. It is concluded that iodized salt is the best medium for I prophylaxis. The I content of Canadian iodized salt (1 part KI or NaI to 10,000) seems unnecessarily high, and is perhaps 10–20 times greater than required. The evidence that iodized salt is potentially dangerous for adult (non-toxic) goitrous individuals is frequently open to criticism, and gravely exaggerated. Further study of this aspect is desirable. A bibliography of 60 references is appended. R. E. THOMPSON

Influence of externally applied preparations to promote growth of hair. A. FORSTER. *Arch. exptl. Path. Pharm.* **144**, 363(1929); *Schweiz. Apoth. Ztg.* **68**, 545–7(1930).—Results of systematic expts. on cats with 6 classes of medicaments (19) do not support the belief that the normal growth of hair can be influenced by the external application of supposedly sp. substances promoting growth, *e. g.*, cholesterol, chem. degradation products of hair or "proteolytic enzymes." Aside from the effect of substances producing excessive stimulation of the skin, or of too high concns., treatment with each of the substances examd., even white vaseline, or 50% alc., although widely different in chem. and pharmacol. characters, may produce an increase in the growth of hair. This fact must be ascribed to the effect of mechanical stimulation, an increased flushing with blood, and perhaps also a cleansing of the skin. However, the mechanical effect may be increased by the use of locally acting chem. stimulants. S. WALDBOTT

Poisoning by seeds of the castor oil plant. P. LIPTÁK. *Ber. Ungar. pharm. Ges.* **1928**, No. 5; *Med. und pharm. Rundschau; Schweiz. Apoth. Ztg.* **68**, 280–1(1930); cf. *C. A.* **15**, 2936; **17**, 1844; **19**, 2533.—An account is given of 3 cases of poisoning by ricinus seed; 2 cases were fatal after, resp., 2½ and 5 seeds only had been eaten. S. WALDBOTT

A study of the treatment of Sydenham chorea. B. WASMER. *Thesis*, Lyon, 1929; *J. pharm. Alsace Lorraine* **57**, 255(1930).—Arsylen has been found an efficient and innocuous remedy (cf. *C. A.* **22**, 813). S. WALDBOTT

Distribution of hydrastine between the erythrocytes and the plasma. R. FABRE. *J. pharm. chim.* [8], **12**, 339–45(1930); cf. *C. A.* **24**, 4865.—Hydrastine-HCl was injected into a dog and 100-cc. samples of blood were taken after 1, 24, 48 and 72 hrs. Na citrate was added and plasma and erythrocytes were sepd. by centrifuging. From each sample the alkaloid was extd. by the Stas-Otto-Ogier method, converted into fluorescent hydrastinine sulfate with H_2SO_4 and H_2O_2, and equal vols. of the solns. were photographed in Wood's light. Again, the erythrocytes proved to have a fixing power for

the alkaloid superior to that of the plasma. Expts. *in vitro*, however, showed no difference. S. WALDBOTT

Bee and wasp poison. DE VASCONCELLES. *Rev. Terap.* **1930**, No. 9; *Therap. Ber.; Schweiz. Apoth.- Ztg.* **68**, 561–3(1930).—Present knowledge of this poison and the methods of combating its effects on man are reviewed; cf. Langer, **1896**; *C. A.* **13**, 2934; **14**, 78; **15**, 378, 2127; **17**, 2916, 3058; **18**, 1534; **23**, 906, etc. Effective antidotes are an injection of 0.1% adrenaline soln. (Samson), or of *racedrine* (racemic ephedrine) (Rubitschang) which prolongs the antidotal effect, or of *rephrine* which is a combination of both. S. WALDBOTT

The chemical examination of *Sida cordifolia*, Linn. (GHOSH, DUTT) **17**. Chloretone as a preservative (POLÁK) **17**.

R. A. GORTNER

Insect oils and fats. J. TIMON-DAVID. *Bull. soc chim. biol* **12**, 395–403(1930); cf. *C. A.* **23**, 3513. The larvae of more than 2 dozen insects studied contain quantities of oil varying from 0.94 to 28.0%. The I values of the oils vary from about 1.2 in the case of some Aphidians (these oils have a high sapon. value) to 164.5 for *Saturnia pyri*, Sch. The non-drying oils are most largely represented. The isolation of hexabromostearic acid by bromination of the acids from *Colaspidema atra*, Ol. (m. p. 178.5°) confirms the presence of linolenic acid in the oil of this insect. Oleic acid is widely distributed in insect oils. The amt. of unsaponifiable matter varies from 0.75% in the oil of *Ergates faber*, L. to 12.5% in that of *Heliotaurus monticornis*, Reitt. The oils of tropical insects have a lower I value than those of insects inhabiting cold countries. Females generally are richer in fat than males. Related species yield oils of a similar type. B. C. A.

A study of the occurrence of trimethylamine in marine animals. A. STANLEY COOK. *Can. Chem. Met.* **15**, 22–3(1931).—Trimethylamine oxide was isolated from the muscle of various species of fish. A method is given for the quant. estn. of $(CH_3)_3NO$ in biol. materials, based on the reduction to $(CH_3)_3NH$ and micro steam distn. and titration of the liberated $(CH_3)_3NH$. W. H. BOYNTON

Occurrence of manganese in insects. II. A. P. VINOGRADOV AND M. V. NEUSTRUEVA. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 6, 127–32; cf. *Compt. rend. acad. Sci. U. R. S. S.* **1929A**, No. 10, 227.—Mn was detd. in a large no. of insect species The av. % of Mn based on live wt. was 10^{-4}, the extreme values being 2×10^{-4} and 5.2×10^{-2}. *Formica rufa* has the max. content. The amt. of Mn depends somewhat on the character of the food, is independent of sex and varies inversely with the atm of gaseous exchange in the insect, those always in motion having the smallest Mn content. With regard to distribution in the body, in *Formica rufa* the head contains an av. % of 2.8×10^{-2}, middle portion 9×10^{-2}, posterio portion 3×10^{-1} based on the dry wt. The latter part of the insect contains the major portion of the alimentary tract and also the gland furnishing the poisonous secretion. Its high Mn content is not due to food residues in the tract since the food of these insects contains less Mn and more Fe than the whole insect. As Mn plays a catalytic role in some fermentations, and as HCO_2H probably results from the action of an oxidative-enzyme upon carbohydrate, the high Mn of the posterior part may be related to HCO_2H production. LEWIS W. BUTZ

Occurrence of vanadium in marine organisms. A. P. VINOGRADOV. *Compt. rend. acad. sci. U. R. S. S.* **1930A**, No. 17, 465–7.—*Phalluris obliqua* and *Ciona intestinalis* contain V; *Molpadia affinis* and *Cucumaria frondosa* do not. It would seem that all Ascidiidae have a V-contg. blood pigment. *Phalluris obliqua* contains 0.0302% of the live wt. The quant. method follows: Fuse the ash with Na_2CO_3 and KNO_3, ppt. Pb vanadate from the aq. soln. of the melt, dissolve the ppt. and titrate the V, reduced by SO_2, with $KMnO_4$. LEWIS W. BUTZ

Molar concentration of snail blood; its factors and variations; influence of the state of activity of the animal. MARCEL DUVAL. *Ann. physiol. physicochim. biol.* **6**, 346–64(1930).—There is no definite relation between the state of activity of *Helix pomatia* and the molar concn. of its blood as tested by the depression of the f. p. NaCl constitutes 70–80% of the total. The molar concn. of the blood of the snail steadily

increases ($\Delta > -0.4°$) until rain or dew allows an imbibition of water. If this hydration does not occur, the animal dies when Δ reaches about $-0.6°$. The total blood CO_2 varies inversely with NaCl, is a max. during the state of activity and constitutes 20–30% of the total molar concn. NaCl and carbonates account for almost the entire molarity of snail blood. It contains only 2–3 mg. of mineral P per l. H. EAGLE

Goldfish susceptible to hydrocyanic acid gas. R. J. RYAN. Calif. Dept. Agr., *Monthly Bull.* **19**, 728(1930).—In 2 cases, orchard fumigation with liquid HCN caused the death of goldfish colonies in ponds located about 100 ft. from the nearest tree. Cf. *C. A.* **14**, 2953–4. C. R. FELLERS

Metabolism of the honey-bee colony during winter. C. L. CORKINS. Wyoming Agr. Expt. Sta., *Bull.* No. **175**, 3–54(1930). —As the external temps. decline below the clustering temp., the metabolic rate is not materially increased. C. R. FELLERS

Cholesterol of decapod crustaceans. A. LEULIER AND A. POLICARD. *Compt. rend. soc. biol.* **103**, 82–3(1930); *Physiol Abstracts* **15**, 142.—A method of extg. the cholesterol from certain crustaceans is described. The cholesterol is similar to that of higher animals, but its rotatory power is somewhat higher. G. G.

Influence of thyroxine on growth of embryos of the pond snail. O. V. HYKES. *Compt. rend. soc. biol.* **103**, 644–6(1930); *Physiol. Abstracts* **15**, 180.—Thyroxine has a depressing influence on the growth of the embryos of the pond snail (*Physa*). It alters the normal process of differentiation but has no direct influence on the duration of development. G. G.

Ion action. IV. The influence of various ions on the rate of the toad heart. SHUN HOMMA. *Japan J. Med. Sci.* **1**, No. 3, 109–47(1929).—Expts. were conducted on the isolated toad heart perfused with oxygenated Ringer soln. The NaCl in it was replaced by salts contg. NaBr, NaI, etc., in various concns. It was found that rubber tubing must not be used in the work. Br and I ions show a positive chronotropic action. In weaker concns. this is not evident. Weak concns. of NO_3 ions show a positive chronotropic effect, but strong concns. are markedly negatively chronotropic. SCN ions are practically the same as NO_3 ions. SO_4 ions are very weak and chiefly negative Anions in a given concn. are very different and the sensitivity of the heart beat for these anions shows a lyotropic series. Li shows a negative chronotropic action, and in concn. of 0.11 mols. the heart is quickly stopped. An antagonism exists between Li and K. **V. The influence of various ions on the excitability of heart strips of the frog.** *Ibid* 147–55.—Expts. on strips of heart muscle from *Rana nigromaculata* in a Ringer strip preparation in which various ions were interchanged showed certain changes in irritability when stimulated with direct current of const. duration Br, I and SCN ions in weak concns. increase the irritability. In high concn. the irritability is more or less decreased. SCN shows the greatest effect. SO_4 produces a diminution, while NO_3 ions cause an increase. The concn. of each anion for max. increase in irritability also shows a lyotropic series. The influence of anions on contractility is independent of the irritability. G H. W. LUCAS

Intracellular oxidation-reduction studies. III. Permeability of echinoderm ova to indicators. ROBERT CHAMBERS, BARNETT COHEN AND HERBERT POLLACK. *J. Expll. Biol.* **7**, 1–8(1931).—Ova of the sandollar (*Echinarachnius parma*) and starfish (*Asterias rubens*) were fertilized and freed from jelly and membranes before they were immersed in solns. of indicators. Eggs that were unstained were injected with 1% $K_3Fe(CN)_6$ as a test for reduced, colorless indicator Toxicity of the various stains was gaged by the subsequent development of the eggs. All indophenols studied penetrated the egg membranes except those with a sulfonate radical. Under aerobic conditions the indicators of the series studied down through methylene blue are reduced within the ova. Penetrating indicators are toxic. Except phenol blue sulfonate the indicators that failed to penetrate were non-toxic. Upon cytolysis or tearing, the indicator is washed from the ovum and the reducing substances pass into the surrounding fluid but retain their activity. C. M. MCCAY

The effect of hydrogen-ion concentration on protozoa, as demonstrated by the rate of food vacuole formation in Colpidium. SYLVIA M. MILLS. *J. Expll. Biol.* **7**, 17–29(1931).—Colpidium cultures (from hay infusion) were suspended in a series of buffer solns. and fed India ink suspensions. The rate of formation of food vacuoles indicates the feeding rate. This attains a max. at p_H 6.0. The max. rate of movement also occurs at this p_H. The mucus produced for food collection has a max. viscosity at a p_H of 8.0. This value lies in the zone of decreased food consumption and movement. C. M. MCCAY

The adaptation of Gunda ulvae to salinity. I. The environment. C. F. A. PANTIN. *J. Expll. Biol.* **7**, 63–72(1931).—*Gunda ulvae* occurs at the mouths of streams

flowing into the salt water of the ocean. It must withstand changes from fresh water to undiluted sea water. It may be exposed to either for periods of several hrs. **II. The water exchange.** *Ibid* 73–81.—These worms immersed in dil. sea water swell. At great dilns. the swelling is less than if they were covered with semi-permeable membranes. In waters contg. only small amts. of inorg. elements the worms swell and die. If these fresh waters are rich in $CaCO_3$ the swelling is much less. NaCl, $NaHCO_3$ or glycerol cannot be substituted for the $CaCO_3$. **III. The electrolyte exchange.** *Ibid* 82–94.—The loss of salts upon the transfer of the worms from sea water to fresh water was measured by elec. cond. Twenty-five % of the salts are lost as the worms imbibe water to double their vol. In waters contg. $CaCO_3$ in which the worms survive their internal salt concn. is reduced to 6–10% of that of sea water. Ca alone seems able to check this salt loss since it cannot be replaced by the other electrolytes studied and since salt loss is continuous in distd. water up to the stage of cytolysis. C. M. M.

Researches on the interior medium of the marine lamprey (Petromyzon marinus)—its variations as the exterior medium is changed. FONTAINE. *Compt. rend.* **191,** 880–2 (1930).—Lampreys were placed in fresh water which was progressively dild. with sea water. After 24 hours' immersion in water of a given concn. the Cl content and osmotic pressure of the blood were detd. The Cl concn. increased but the ratio of Cl to other ions in the blood decreased. Mucous retards the appearance of pathol. symptoms when the lamprey is placed in salt water. J. G. MCNALLY

A comparison of the action of magnesium chloride on the respiratory activity and on the contractility of the frog ventricle. J. LEIBOWITZ AND A. SCHWEITZER. *Biochem. Z.* **229,** 291–5(1930).—At the close of the seasonal hypersensitivity of the frog heart to $MgCl_2$ it is found that Mg salts exert an inhibitory effect upon tissue respiration which is parallel to the diminishing inhibition of the contractility. The inhibiting action of small doses of Mg on the oxidation can be shown during the summer in the heart but not in the liver. S. MORGULIS

Action at a distance and the development of the eggs of the sea urchin. New experiments. J. MAGROU AND MME. M. MAGROU. *Compt. rend.* **191,** 802–4(1930); cf. *Ibid.* **186,** 802(1921); **188,** 733(1929); **189,** 779(1929).—Eggs of the sea urchin (*Paracentrotus lividus*) are markedly affected at a distance by exposure to bacterial suspensions and chem. mixts., although sepd. therefrom by a quartz flask with a ground and hydraulically sealed stopper. These expts. were repeated with controls not exposed to the above agents, and slight irregularities of growth in the controls suggested that the larvae do not perfectly accommodate themselves to the sealed flask. A new set of expts. was therefore performed in which the active substances rather than the eggs were placed in the closed vessel. The results confirmed the action at a distance effected by *B. tumefaciens*, and glucose in an oxidizing medium. The open top of a tube contg. the active substance may be bent down and introduced into a control tube without effect on the development of the larvae, thus showing that the action at a distance is not due to a substance capable of traveling through this tube. T. H. RIDER

Actions at a distance on fertilized eggs, sperm and virgin eggs of the sea urchin (Paracentrotus lividus Lk.). J. MAGROU AND MME. M. MAGROU. *Compt. rend* **191,** 963–5(1930); cf. preceding abstr.—Sperm of *Paracentrotus lividus* Lk. exposed in quartz vessels to the same conditions as reported in the previous article, when used to fertilize normal virgin eggs, gave larvae which developed abnormally. Virgin eggs likewise treated before fertilization gave abnormal larvae. The exposure of eggs or sperm in the same manner to a soln. of uranium nitrate too weak to affect a photographic plate in 24 hrs. still produced abnormalities. T. H. RIDER

Chemical processes of cellular division. LOUIS RAPKINE. *Compt. rend.* **191,** 871–4(1930).—Accepting the hypothesis (Harris, *Proc. Roy. Soc.* (London) **B94,** 426 (1923)) that cellular division is preceded by a denaturation of proteins accompanying a splitting of the cellular lipoid-proteins, R. investigated the occurrence of the SH radical (I) during the stages before and after the division of eggs of *Paracentrotus lividus* Lk. Virgin eggs showed 35 mg. I per 100 g. eggs. Thirty min. after fertilization this figure dropped to 10 mg. I, and 10–15 min. before the first division increased to 46 mg. I. Eggs exposed to the action of 0.00001 *M* $HgCl_2$ 20 min. after fertilization for a period of 5 min. then transferred to sea water or sea water contg. $PhNH_2$ or cystine failed to develop. Transferred to a 0.001 *M* soln. of cysteine in sea water, however, 70–90% developed. Thus cellular division can be controlled by the removal or addn. of I. T. H. R.

Variation in the response to light in Ameba proteus with special reference to the effects of salts and hydrogen-ion concentration. S. O. MAST AND H. R. HULPIEU. *Protoplasma* **11,** 412–31(1930).—The rate of reaction is largely dependent upon age

size, etc., of the ameba. Under comparable conditions increase in HCl causes increase in reaction time. The reverse effect is obtained with CO_2. An increase in concn. of the chlorides of K, Mg and Ca causes a decrease in reaction time. In solns. of NaCl there is no consistent relation. M. H. SOULE

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Amendment to the Federal food and drugs act of June 30, 1906. Food and Drug Administration, U. S. Dept. Agr., *Service and Regulatory Announcements, F. D.* No. **1**, Suppl. 1, 1930.—The text of the amendment of July 8, 1930, to Section 8 of the act is given. The Secretary of Agriculture is authorized to promulgate, from time to time, such standards of quality, condition and (or) fill of container for *canned foods*, as will in his judgment promote honesty and fair dealing with the consumer. Canned food coming within the jurisdiction of the act (except meat and meat food products subject to the Federal Meat Inspection Act, and canned milk) which fall below such standards is misbranded unless its package or label bears a plain and conspicuous form of statement promulgated by the Secretary, indicating that it falls below the standard. Canned food is defined as "all food which is in hermetically sealed containers and is sterilized by heat." It is provided that nothing in the amendment "shall be construed to authorize the manufacture, sale, shipment or transportation of adulterated or misbranded foods." H. A. LEPPER

Definitions and standards for food products. Food and Drug Administration, U. S. Dept. Agr., *Service and Regulatory Announcements, F. D.* No. **2**, Suppl. 2, August, 1930.—Definitions and standards are adopted for *fruit juice, grape juice, orange juice* and *whole-wheat flour*. The standard for *flour* has been revised. *Ibid* Suppl. 3, January, 1931.—In the definitions and standards for food products adopted as a guide for officials of the department in enforcing the Federal food and drugs act the term "sugar," with or without the parenthetical expression "sucrose," as used to designate the sweetening agent in manufactured food products, is to be interpreted to include dextrose (pure refined corn sugar). This is in keeping with the announcement of the Department permitting the use of pure refined corn sugar as an ingredient of food in which sugar (sucrose) is a recognized element without declaration on the label of the product. The restrictions on the adulteration or imitation of any natural product, such as honey, by the addition of any sugar are not affected by the ruling. H. A. LEPPER

Crude fiber determination with the aid of a filter of a new type. K. FEIST AND E. KUNTZ. *Z. Untersuch. Lebensm.* **59**, 480–3(1930).—An app. is described by which dependable results are obtained in min. time. C. R. FELLERS

Detection of hard wheat grits. E. BERLINER AND R. RÜTER. *Z. ges. Getreidew.* **16**, 212–3(1929).—A criticism of Kühl's test (*C. A.* **24**, 4557). B. C. A.

Detection of hard wheat grits. H. KÜHL. *Z. ges. Getreidew.* **16**, 213–6(1929); cf. *C. A.* **24**, 4557.—A reply to Berliner and Rüter (preceding abstract) and statement of exact conditions. B. C. A.

Effect of harvesting in different stages of ripening on the valuable constituents of cereals. F. BERKNER AND W. SCHLIMM. *Landw. Jahrb.* **72**, 269–91(1930).—Late harvested grain has greater weight per 1000 grains. There is a migration of the starch to the grain in the later stages of ripening and a rapid increase in the protein content between the "milky" stage and ripeness. GEORGE R. GREENBANK

Biometric analysis of cereal-chemical data. I. Variation. ALAN E. TRELOAR. *Cereal Chemistry* **8**, 69–88(1931).—T. explains the fundamentals of statistical analysis. He gives several formulas which are used by the biometrician. Histograms are given with fitted curves superimposed. The significance of statistical consts. is explained. L. H. BAILEY

Baking value of flour and possibility of determining it in the laboratory. A. TASMAN. *Chem. Weekblad* **27**, 138–43(1930).—An account is given of the attempts to correlate chem. and phys. consts., particularly viscosity and swelling power, with baking properties. Valuable information may be obtained by detns. of viscosity in the presence of regularly increasing quantities of acid, the differences in viscosity being plotted to form a curve. From the form of the curve for a given flour, rough estimates may be made of the ash content, gluten content and swelling power. B. C. A.

The stability of leavening in self-rising flour. PAUL LOGUE AND ELIZABETH MCKIM. *Cereal Chemistry* **8**, 24–9(1931).—The consumption of self-rising flour in

the U. S. is increasing more rapidly than the consumption of plain flour. The rate of premature decompn. of self-rising flour varies directly as the moisture content. Self-rising flours contg. less than 12.5% moisture are relatively stable. Self-rising flours contg. more than 12.5% moisture decompose more rapidly and result in alk. baked products, unless this premature decompn. is compensated for in increased acid leavening agent. An explanation of the increased alky. accompanying premature decompn. is offered in the mechanism of the reactions involved. L. H. BAILEY

Relation of peptization of wheat flour protein to loaf volume. R. H. HARRIS. *Cereal Chemistry* **8**, 47-63(1931).—A series of 11 experimentally milled flours was peptized by 3 methods and the percentage of total protein extd. was computed. The correlations between improver loaf vol. and percentage of total protein peptized were also computed. The quantity of protein removed increased quite rapidly at first, but no appreciable change was detected after the initial 30 min. Temp. did not appear to have any significant effect upon the quantity of protein extd. except in the water suspension, when a slight increase with rise in temp. was noticed. Forty-four flours of 75% extn., milled from 1929 crop Saskatchewan Marquis wheat of contract grade, were peptized by 0.5 *N* soln. of KBr and $MgSO_4$, and the protein extd. was calcd. as percentage of the total protein, also as peptized and non-peptized protein fractions of the flour. Correlations between the percentage of total protein peptized and improver loaf vol. were lower than those between total protein and improver loaf vol. and show less probability of forecasting loaf vol. The relationship between non peptized protein and improver loaf vol is not significantly different from that involving total protein and improver loaf vol., and is of equal value in predicting baking strength The corresponding correlations obtained with the basic loaf vol were not so large, and are relatively of less practical importance. Twelve flours milled in a similar manner from 1928 pure strain Marquis grown at various Saskatchewan points including grades from No. 1 Northern to No. 6 gave a higher neg. correlation between the percentage of total protein peptized and improver loaf vol than between the percentage of total protein peptized and basic loaf vol L. H. BAILEY

Predetermining flour soundness. D. A. COLEMAN. *American Miller* **58**, 434 (1930).—In an endeavor to find some method of detg. the soundness of flour without going through the time-consuming methods of milling and baking, it was observed that the acidity of the fat is much greater in unsound wheat than in normal wheat. It was also observed that the normal acidity of the different classes of wheats varies widely Thus the acidity of the fat of sound hard red winter wheat does not exceed 8.5; hard red spring wheat, 5.5; soft red winter wheat, 8.0; Durum wheat, 4.0; and white wheat, 5.5. The acidity of the fat of certain types of damaged wheat was found to be: dank and wet wheat, 8.6-16; musty wheat, 9-15; sour wheat, 9-22; skin-burned wheat, 21-38 and mahogany, bin-burned wheat, 35-44. The method of testing the acidity consists in removing the fat from the material with petroleum ether, recovering the fat from the ether to det. the quantity present and dissolving the fat in a suitable solvent so that the free fatty acid can be detd. The acidity of the free fatty acids present is expressed per g. of fat. L. H. BAILEY

Wheat and flour studies. XVII. Factors influencing the viscosity of flour-water suspensions. 4. The effect of extraction with solutions of potassium and sodium halides. ARNOLD H. JOHNSON. *Cereal Chemistry* **8**, 39-43(1931); cf. *C. A.* **24**, 3287.—The viscosity of flour-water suspensions extd. with 1.0 and 0.5 *N* solns. of the K and Na halides are higher than those of similar suspensions extd. with distd. water. The viscosities decrease according to the lyotropic series of the anions I > Br > Cl > F. Glutenin is not removed on extn. of a flour suspension with the halides of K and Na. L. H. BAILEY

The march of acidity in stored flour. II. M. C. MARKLEY AND C. H. BAILEY. *Cereal Chemistry* **8**, 29-38(1931); cf. *C. A.* **24**, 897.—A higher correlation of ash content with acidity as detd. by the A. O. A. C. method was found in freshly milled flours than the ash content with acidity detd. by the Greek method. The difference between Greek acidity and A. O. A. C. acidity in freshly milled flours was highly correlated with the ash content. Earlier assumptions that the A. O. A. C. tentative method for acidity indicated the relative rate of production of acid-reacting substances during the extn. with water received support from these recent studies. The rate of change in acidity of flours stored at 25° was highly correlated with ash content. It was estd. that flours contg. the percentages of ash included in the 4 grades or qualities described in the present Greek specifications will contain in excess of the max. limits of acidity after 43 to 52 days when stored at 25°. L. H. BAILEY

Recognition and determination of the polyfructoses. II. Determination of tri-

fructose anhydride for estimating the rye content of flour. C. I. KRUISHEER. *Rec. trav. chim.* **50,** 153–63(1931); cf. *C. A.* **24,** 4872.—Treat 12.5 g. of flour with 50 cc. of 70% alc. and shake vigorously for an hr. in a closed flask. Filter and transfer 25 cc. of filtrate to a centrifuge tube and treat with 5 cc. of *N* NaOH in 70% alc. Mix and allow to stand overnight. Centrifuge, pour off the liquid and wash the residue twice with 2 cc. portions of 70% alc. Dissolve the ppt. in 10 cc. of hot water and neutralize to methyl orange with 0.25 *N* H_2SO_4. Transfer the soln. together with 15 cc. more of water to a 50 cc. measuring flask, add 2.5 cc. of 9.5 *N* HCl and heat 10 min. at 68–70° to invert the sugar. After cooling, neutralizing and again cooling, the soln. is mixed and in 10 cc. of the soln.; the total reducing power (R_2) is detd. preferably by the method of Schoorl. To det. the fructose content (F_2), take 20 cc. of the inverted liquid and treat with hypoiodite. From the values R_2 and F_2 the content in trifructose anhydride (T) can be computed and also the saccharose obtained. Take the liquid poured off after the centrifugation described above, make neutral to methyl orange and evap. to a small vol. Transfer to a 50 cc. measuring flask, dil. to about 25 cc., add 2.5 cc. of 9.5 *N* HCl and invert 10 min. at 68–70°. Continue as described above to det. R_2 and F_2. The results in the analysis of about 40 samples are shown. In bolted rye meal 1.5–2% of a trifructose anhydride was obtained, but only 0.1–0.3% in wheat flour. On standing the content increases. On the basis of the above behavior, the rye content of flour can be estd. to within about 10%. The necessary calcns. are described. W. T. H.

Determination of butter fat. E. SCHWEITZER AND J. GROSSFELD. *Z. Untersuch. Lebensm.* **59,** 494–501(1930).—For 3 yrs. a large no. of samples of butter, mixts. of butter and margarine, and margarine were examd. for butyric acid and Reichert-Meissl values. The mean % deviations from the normal values of 20.0 and 27.0 were ±7.4 and ±10.0, resp., for normal butter. The mean of the Reichert-Meissl values for 37 samples was 28.7, which corresponds closely with the van Raalte value of 28.4. The ratio of the butyric acid value to the Reichert-Meissl value was in excess of 0.66 in all cases (av. 0.713). Other relations are discussed. C. R. FELLERS

Masking of the color reaction of margarine. B. HEPNER AND S. ZALC. *Przemysl Chem.* **14,** 412–5(1930).—Under some conditions the use of oil of sesame for distinguishing between butter and margarine is not satisfactory because of the difficulties encountered in the Baudouin reaction. It depends on the presence of sesamol in the oil of sesame which may be destroyed during refining either by acid reagents or high temp. (180°). Rancidity of the oil of sesame or of margarine produces under the influence of HCl an intensive coloration which masks the Baudouin reaction. This reaction was found unreliable in all cases of rancid margarine. KOH should be used for the removal of phenolic dyes used for coloring margarine when these mask the furfurol reaction. A. C. ZACHLIN

Determination of the milk proteins. II. GEORGE M. MOIR. *Analyst* **56,** 73–8 (1931); cf. *C. A.* **25,** 1004.—On the basis of the isoelec. point it is suggested that casein be defined as the material pptd. from cow milk at p_H 4.6 by AcOH buffered with NaOAc. By digesting with *N* NaOH and detg. the increase of the formol titration and by studying the rate of oxidation, it is shown that the casein pptd. under the above conditions is identical with that pptd. by AcOH alone at p_H 4.2. W. T. H.

Number and character of bacteria and their subsequent development in pure and in contaminated milks. HENRI L. BERARD. *Sci. Agr.* **11,** 369–77(1931).—Contamination of milk with manure or soil bacteria not only augments the initial nos. of organisms present, but these types develop in the milk during several days storage. Temp. increases during storage of contaminated milks cause great increases in soil and manure bacteria in milk. A contamination of approx. 0.1 g. of soil or manure per l. does not produce marked changes in the character of the milk flora if the temp. is held at about 60°F. If held below 50°F. there is a considerable increase in the no. of liquefiers and alkali producers; this is due principally to staphylococci. C. R. FELLERS

Modification of the methylene blue reduction test and its comparative value in estimating keeping quality of milk. C. K. JOHNS. *Sci. Agr.* **11,** 171–90(1930).—The suggested modifications to the standard test are: preliminary incubation at 12.8° for 18 hrs. and mixing of contents of tubes not decolorized in 6 hrs. when subsequently incubated at 37.5°. These modifications shorten the reduction time, and the mixing reduces the variations between duplicate tubes. The chief advantages are greater convenience, improved accuracy on high-grade milks, and closer correlation with keeping quality. In a study of 145 samples by the ordinary and the modified reduction tests, acidity increase, and plate and breed counts, the modified reduction test proved to be the method best suited to aid in ranking a series of samples according to keeping quality. C. R. FELLERS

Keeping quality of combined fat extraction, fixing and staining solution used in the direct microscopic technic for counting bacteria in milk. R. W. NEWMAN. Calif. Dept. Agr., *Monthly Bull.* 19, 667(1930).—No deteriorative changes were apparent after 3 yrs. use. The bottles were kept well stoppered. C. R. FELLERS

Investigation of the occurrence of B. abortus (Bang) in the milk of English herds (county of Somerset). D. R. WOOD AND E. T. ILLING. *Analyst* 56, 105(1931).—The deposit obtained by centrifuging 100 cc. of milk was injected subcutaneously into a guinea pig. After 4 weeks the pig was killed and cultures were made from the interior of the spleen on glucose, neutral red and vitamin agar in an atm. of 10% CO_2 and 90% air at 37°. The glucose and neutral red show at once whether any growth obtained is due to contamination with *B. coli*. *B. abortus* was identified by its failure to grow except under reduced O_2 tension and by agglutination with standard anti-serum. The expts. were carried out concurrently with the examn. of the milk for tubercle bacilli (*C. A.* 24, 5387). *B. abortus* was found in the milk of 4 out of 379 herds tested. W. T. H.

Effect of the electropure process of treating milk upon bacterial endospores. A. J. GELPI, JR. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention* 162–7 (1930).—Although the cultures originally showed 80 to 90% sporulation no spore-formers were found after the samples were subjected to the electropure process. Further expts. indicated that purification of milk by the electropure process is brought about by the aid of another factor besides heat. K. D. JACOB

Retained milk. OTAKAR LAXA. *Ann. fals.* 23, 609–10(1930).—Four cows which had been unmilked for 3 days furnished on milking only about 100 cc. of thick, brownish-tinged, colostrum-like milk, having an odor of burnt milk and the following compn.: water 78.40, fat 10 15, casein 2.65, albumin and globulin 0, albumoses and peptones 2.92, amino acids 1.78, lactose 1.50, ash 1.10, undetd. 1.50%. The ash contained 23.2% CaO and 16.76% Cl. A. PAPINEAU-COUTURE

Investigation of artificial whole-milk powder. P. WEINSTEIN. *Z. Untersuch. Lebensm.* 59, 515–6(1930).—Microscopic examn. of a powder showed a relatively high proportion of large fat globules. Extn. of the fat with light petroleum ether gave a yield of 18.0%. The *n* and other consts. showed the oil to be largely olive oil which had been used for adulterating skim-milk powder. C. R. FELLERS

Studies concerning the daily yield and fat content of the milk of the half-wild yak in the Siberian Altai Mountains, together with a contribution to the investigation of milk and fat inheritance in primitive breeds. J. W. AMSCHLER. *Z. Tierzucht. Zuchtungsbiol. Tiernahr.* 20, 293–308(1931).—Studies are reported of the yield and fat percentage of the milk of 116 yaks and 6 yak crosses with Altai cattle living on sparse pasture in Siberia. The daily milk yield of the yak cows varied from 1.2 kg. to 4.1 kg. with a mean of 2.73 kg. The fat varied from 4.23 to 8.50% with a mean of 6.09%. The range of yield for the yak crosses was 2.4 to 4 kg. with a mean of 3.20. The fat varied from 4.59 to 6.21% with a mean of 5.45%. L. A. MAYNARD

Non-acid Babcock method for determining fat in ice cream. O. R. OVERMAN AND O. F. GARRETT. Ill. Agr. Expt. Sta., *Bull.* No. 360, 393–406(1930).—The method requires 2 reagents, *A* and *B*. *A* is made by mixing 75 cc. of c. p. NH_4OH, 35 cc. of BuOH and 15 cc. of 95% EtOH (denatured is satisfactory). Reagent *B* is made by dissolving with heat 200 g. of Na_3PO_4 and 150 g. of NaOAc in 1 l. of water. To make the test, weigh 9 g. of the well-mixed sample into a 8 or 10% milk test bottle (or a 20% ice cream test bottle), add exactly 2.5 cc. of *A* and mix thoroughly. Then add 9–10 cc. of *B* and thoroughly mix. Place the test bottle in a shallow water bath and heat to boiling, continuing the heating for several min. During the heating shake the bottles several times. The fat seps. after 15–30 min. and forms a clear yellow layer at the top of the liquid. After the fat sepn. is complete, place the test bottle in the centrifuge and whirl successively, as in the Babcock test, for 5, 2 and 1 min. Add hot water, as in the Babcock test, but do not acidify the water. Then place the bottle in the hot-water bath (130–40°F.) for 5 min In reading the results measure from the bottom of the fat column to the top of the upper meniscus. Comparisons were made with the Official Roese-Gottlieb method. Of the 54 samples tested, 64.82% came within ±0.1% of the R.-G. values, 24.07% fell within ±0.1–±0.2 and 11.11% between ±0.2 and ±0.3%. The av. difference for all samples was ±0.0675%. The method is fairly rapid, inexpensive and sufficiently accurate for com. use. A large no. of detns. can be made concurrently. Twenty-six references are cited. C. R. FELLERS

Standardization of milk with skim milk for the manufacture of Cheddar cheese. H. C. HANSEN AND D. R. THEOPHILUS. Idaho Agr. Expt. Sta., *Bull.* 174, 3–16(1930).—See *C. A.* 25, 360. C. R. FELLERS

The detection of horse meat as an adulterant in sausage and other studies of the precipitin test. F. M. BOLIN. *J. Am. Vet. Med. Assoc.* **31**, 163–70(1931).—A horse meat ext. antiserum was found better than horse serum antiserum for the detection of horse meat adulteration in sausage. Rabbits immunized to a cooked product had sp. precipitins for the uncooked sp. protein, and at the same time had nonsp. precipitins for cooked meats of different species. Meats heated at 15 lb. pressure for 10 min. were unsuitable as antigens for immunization purposes. Immature animals were unsatisfactory in the production of precipitins. Meats of closely related species were differentiated only by the length of time necessary for the reaction to occur.
RACHEL BROWN

"Adulterated" olive oil in sardines. H. WEWERS. *Z. angew. Chem.* **43**, 656 (1930).—High I values of the oil used in prepg. sardines, thought to be due to adulteration of the olive oil, were found to be assocd. with the extn. from the sardines of a fat of very high I value by the pure oil. B. C. A.

Increase in the p_H of the white and yolk of hen eggs. PAUL FRANCIS SHARP AND CHARLES KELLY POWELL. *Ind. Eng. Chem.* **23**, 196–9(1931); cf. *C. A.* **24**, 4558.—The p_H of eggs is an important factor in detg. their rate of deterioration. Eggs with a low p_H deteriorate less rapidly. The p_H of the white increases rapidly as the result of an escape of CO_2 gas. This may be delayed by storing at low temp. or by oil dipping. After 15–25 days' storage at high temp. the p_H decreases. The p_H changes of the yolk are smaller. In com. incubators the p_H of the white after 2 days is 9–9.2, which may affect the developing embryo. A higher CO_2 pressure would remedy this.
AMY LEVESCONTE

Preservation of fruits and vegetables by freezing storage. M. A. JOSLYN. Calif. Agr. Expt. Sta., *Circ.* **320**, 35 pp.(1930); cf. *C. A.* **23**, 3030.—At temps. of 10°F., molding, fermentation and bacterial spoilage do not occur and the normal ripening and respiration processes are effectively arrested. The com. methods are outlined. Deteriorative changes due to oxidative enzymes go on slowly at freezing storage temps. and cause surface discoloration in some fruits. The usual ratio of fruit to sugar is 2 or 3 to 1. A sirup pack is preferred to a mixt. of fruit and dry sugar, as surface discoloration is thus greatly reduced and better distribution of the sugar is secured. After thawing, cold-packed fruits keep from 3 to 7 days without actual spoilage. Vacuum packing of fruit for freezing possesses the advantage that nearly all the O is excluded from the container, thus decreasing oxidative changes in the frozen product. Fruit juices may be frozen without much injury to their flavor. Though most vegetables may be successfully stored in the frozen state, slight changes in flavor and the inability to keep for more than a few hours after thawing render frozen vegetables less suitable for com. exploitation than fruit. C. R. FELLERS

Storing canned fruits at high temperatures injures quality. E. F. KOHMAN. *Food. Ind.* **3**, 77(1931); cf. *C. A.* **24**, 1679.—The hydrolysis of the anthocyanin pigments in red fruits is greatly increased at high storage temps The color base separates from the glucoside base and is thrown out of soln. as a brown amorphous mass which no longer retains any of the original color. This mass causes some darkening of the fruit, but more important is the loss of bright natural color. Prompt and efficient cooling after the heat treatment, as well as subsequent cool storage, is strongly recommended as a means of better preserving the color of fruits. C. R. FELLERS

Research answers (food) packing and bottling problems. I. C. G. HICKS. *Glass Container* **10**, No. 4, 8–9, 22–30(1931).—Animal feeding tests for *vitamin C in tomato juices* prepd. in various ways showed that for max. retention of vitamin C, complete air removal is necessary. Tomato juice packed without treatment to remove air was entirely devoid of vitamin C. Vacuum sealing of the container was ineffective, but vacuum treatment of the juice before bottling combined with vacuum sealing, proved most effective in conserving the vitamin C in the final product. By decreasing the particle size by homogenization, sepn. of the pulp and juice was largely prevented. Eight-oz. bottles of tomato juice were effectively sterilized when subjected to a holding period of 15–20 min. in a water bath. C. R. FELLERS

Disinfecting power of bleaching powder with special reference to its application to the disinfection of vegetables. ENJI BANNAI AND HIDEKICHI HABU. *J. Pub. Health Assoc. Japan* **6**, No. 7, 3–6(1930); *U. S. Pub. Health Eng. Abstracts* **11**, Mi, 2(Jan. 31, 1931).—The disinfection with bleaching powder of such vegetables as greens, radishes, turnips, spinach, etc., could not be satisfactorily accomplished, irrespective of the concn. of the soln., length of exposure, no. of bacteria attacked, or time elapsed after contamination of the vegetables. C. R. FELLERS

Storage of potatoes. N. D. VYAS. *Agr. J. India* **25**, 408–16(1930).—Loss of

potatoes during storage for 32 weeks was reduced to 28–31% by wt. by storage in cinders or charcoal as compared with a loss of 40–90% by storage in coarse sand. Addn. of lime slightly lowered the preservative power of the storage media. The preservative action of cinders and charcoal seems to be due to their ability to absorb moisture and gases given off during rotting of the potatoes, thus preventing infection of sound potatoes. Rotting of potatoes was increased by treating them with 5% H_2SO_4 for 3 hrs. before storage. K. D. JACOB

Chemical studies on cannery peas. ANON. N. Y. Agr. Expt. Sta., *49th Annual Report*, 50 1(1930).—By means of a puncture tester the toughness of peas was found to increase regularly with size. Varieties varied considerably in toughness but the toughness of the fresh pea coincided with that of the processed (canned) pea as judged by experts. Chem. analyses were made for reducing sugars, sucrose, starch, sol. and insol. N, ash, Ca and alc-insol. residue on a large no. of samples. The following tentative phys. and chem. criteria are established for high-quality canning peas: The puncture value should not exceed 40 g. per sq mm. The starch-sugar ratio should not be over 1.0. The insol.-sol. N ratio should not exceed 3.0 and the CaO content of the fresh skins should not be over 0.06%. Sucrase, diastase and protease are very active in macerated peas and may cause some deterioration in quality. Toughness and Ca content are correlated. Effects of fertilizer treatment on quality are being studied. C. R. FELLERS

Microscopy and histochemistry of certain fruits. ANNELIESE NIETHAMMER. *Z. Untersuch. Lebensm.* **59**, 501–6(1930), cf. *C. A.* **24**, 4076, 5890.—The endocarp of oranges contains crystals of CaC_2O_4 which can be isolated and identified by treatment of the fruit with concd. H_3PO_4 followed by sublimation under reduced pressure. After storage for several weeks, slow resorption of the crystals occurs with concomitant formation of AcH. Lemons and mandarins exhibit identical phenomena. Pears contain characteristic inclusions, and in the ripe condition AcH, which is present in greatest abundance in over-ripe fruit. Upon sublimation, ripe pears give malic and citric acids, while over-ripe pears contain $H_2C_2O_4$ in addn. The AcH test is always pos. in plums, and CaC_2O_4 can be detected. From bananas in the ripening stage, malic acid can be sublimed, but after prolonged storage only traces of $H_2C_2O_4$ and tartaric acid can be detected. Unripe tomatoes contain considerable amts. of malic acid with traces of tartaric acid and $H_2C_2O_4$, while ripe samples contain malic, citric and tartaric acids. AcH is present only in ripe tomatoes. C. R. FELLERS

Papaya culture in Hawaii. W. T. POPE. Hawaii Agr. Expt. Sta., *Bull.* **61**, 40 pp. (1930). —The *chem. compn. of the ripe and immature fruits* was detd. Improved varieties gave the following av. results: total solids 13.39, ash 0.76, acid (as H_2SO_4) 0.132, protein 0.484, sucrose 10.14, total sugars 10.61, fat 0.105 and fiber 0.962. The green fruit contains practically no starch or sucrose and only a small amt. of reducing sugars. The latter increase rapidly with approaching maturity. *Papain*, a powerful digestive enzyme, is present in the milky juice. Meat rubbed with a slice of green juicy papaya becomes tender as a result of the action of the papain. Because of the size, wt. and delicate structure of the fruit great care is necessary in harvesting, packing and shipping. A bibliography is given. C. R. FELLERS

Isolation of quinic acid from fruits. E. F. KOHMAN AND N. H. SANBORN. *Ind. Eng. Chem.* **23**, 126(1931).—The BzOH content of prunes and cranberries is too low to explain their acid reaction after digestion. Quinic acid, which the authors have isolated from these fruits and have detected in grapes, is more probably the cause. AMY LEVESCONTE

Sampling of apples for arsenical spray residue determinations. J. R. NELLER. *Ind. Eng. Chem., Anal. Ed.* **2**, 382 4(1930). A statistical study of the sampling of apples that had been washed with dil. HCl showed that the av. probable error of single samples of 6 apples each was 8.2%, while that of duplicate samples was 5.36% of the total arsenic on the fruit. The av. probable error of analysis was 7.4%. The error of sampling is considerably reduced by using duplicate rather than single samples but the rate of reduction is much less for triplicates, quadruplicates, etc. J. R. NELLER

Artificial removal of astringency in kaki. KINZIRO KAKESITA. *Proc. Imp. Acad.* (Japan) **6**, 397–8(1930).—The expressed juice of Japanese astringent persimmons (kakishibu) is coagulated at room temp. by the addn. of AcH(HCHO or EtCHO may also be used). It is believed that this action is caused by the polymerization of tannic substances in the fruits with the formation of insol. tannin-colloid and that the astringency in kaki is thereby removed. C. J. WEST

Dehydration of grapes. P. F. NICHOLS AND A. W. CHRISTIE. **Calif. Agr. Expt. Sta., *Bull.* 500**, 3–31(1930).—A new type of raisin grape called the "Golden Bleached

Thompson" is the principal variety which is dehydrated, though wine and juice grapes can also be advantageously dehydrated. The grapes are dipped before dehydrating in a lye bath (0.5–1.0% NaOH) kept at 200–12°F. In sulfuring the dehydrated product, 2–4 lb. of S must be burned for each ton of fruit, giving a SO_2 concn. in the raisins of 200–1000 p. p. m. The finishing temp. should not exceed 165–70°F. with a relative humidity of 25%, or burning will result. Dehydration offers improvement in quality and yield by making it safe to defer picking until full maturity is reached. Special dips contg. olive oil, glycerol and mineral oil offer possibilities for improvement of color and keeping quality. Sulfuring did not adversely affect insect infestation. C. R. F.

Investigations on grape juice manufacture. ANON. N. Y. Agr. Expt. Sta., *49th Annual Report* 55(1930).—The colloidal material in Concord grape juice affects adversely the color and clarity of the juice and delays the settling out of tartrate crystals. By removal of the colloids, crystallization takes place in a much shorter time, thus allowing the juice to be bottled. The colloidal matter in grape juice contains about 8% protein and 7% pectin, the rest being polysaccharides of unknown nature.

C. R. FELLERS

The preservation of fruit juices, sweet must, etc. A. MEHLITZ. *Konserven Ind.* **1930,** 742–4, 756–8, cf. *C. A.* **25,** 153.—M. describes further work on the preservation of fruit juices by centrifuging the juices through a De Laval separator, clarifying by digestion with an enzymic ext. of *Aspergillus oryzae*, filtering through an asbestos prefilter and then through a Seitz E K germ filter. It was necessary to reduce the active acidity of the red currant juice from p_H 2.72 to 3.66, and of white currants from p_H 2.89 to 4.15 to obtain better enzyme action. In every instance the juice treated with *Aspergillus oryzae* filtered much more rapidly than the untreated juice. After 4 months standing the filtered juices were clear and of good color and taste. F. P. G.

Study of the factors affecting the jellation of fruit juices and pectin solutions. P. B. MYERS AND G. L. BAKER. Del. Agr. Expt. Sta., *Bull.* **167,** Ann. Rept. of the Director 22–4(1930).—With lemon albedo as raw material 4 series of pectins were prepd., 2 series each at temps. of 80° and 100°. The yield, jelly grade, jelly units, ash, methoxyl and p_H of the pectins in each series were detd. The yield of pectin increased with the temp. of the extn., other conditions remaining const. This condition existed only when the p_H of the extg. medium was at 1.50 or above. When below 1.50 the yield of pectin increased with the temp. of the extn. up to some temp. below 100° and then decreased as the temp. was increased to 100°. For instance, when the extn. was conducted at p_H 0.8, the yield of pectin increased from 20.5% at 40° to 30.8% at 85°, and then decreased to 28% at 100°. At some H-ion concn. between p_H 1.5 and 0.8 and below, the hydrolysis of pectin to some alc.-sol. compds. is faster than the hydrolysis of protopectin to pectin at temps. below 100°. The yield of pectin at any temp. could not be increased to the optimum yield obtained at a temp. above it by increasing the time of extn. The optimum jelly grade of pectins, extd. by heating 30 min. while varying the p_H of the extg. medium, decreased as the temp. of the extn. increased. Since the yield of pectin increased with the temp. of the extn. while the jelly grade decreased with increase in temp., the product of the 2 (jelly units) tends to remain const. so that the great variation in jelly units with the temp. of the extn. that was previously expected did not occur. C. R. FELLERS

Determination of sorbitol in jams. C. F. MUTTELET. *Ann. fals.* **23,** 602–5 (1930); cf. *C. A.* **24,** 3289.—Cherry juice was found to contain 0.290% sorbitol; red gooseberry and strawberry juices contained none. Home-made cherry jam contained 0.125%, while home-made gooseberry jam and strawberry jam contained none. Com. so-called "pure fruit" gooseberry jam and "pure fruit" stawberry jam contained 0.135% and 0.075% sorbitol, resp., indicating the presence of apple juice, which was confirmed by the presence of malic acid. Com. compd. cherry jam contained 0.025% sorbitol, indicating that there was but little cherry (really only cherry fragments in sugar sirup which was jellied by addn. of com. pectin). A. PAPINEAU-COUTURE

Determination of so-called crude fiber (cellulose) in cacao. K. KÜRSCHNER AND A. HANAK. *Z. Untersuch. Lebensm.* **59,** 484–94(1930).—The method previously devised (Kürschner and Hoffer, *Tech. Chem. Papier- Zellstoffabrikation* **26,** No. 8–9(1929)). for the detn. of cellulose in wood has been modified by the substitution of AcOH for EtOH in the mixt. used for decomposing the noncellulose elements. The sample of defatted cacao, approx. 0.3 g., is intimately mixed with 15 cc. of 80% AcOH and 1.5 cc. of HNO_3 (d. 1.4) in a flask fitted with a ground-in air condenser. The mixt. is gently boiled for 15–25 min. and then filtered through a large-pored porcelain or glass filter previously moistened with AcOH. The residue is washed successively with 7–10 cc. of the hot mixt. of HNO_3 and AcOH, hot water, a few drops of EtOH, 5–10 cc. of

Et_2O, 1–2 cc. of the acid mixt. and finally hot water, until all traces of AcOH have been removed, the flask and walls of the filter being washed at each stage. The residue is dried at 105–8° and weighed. By this method, which gives most consistent results, white undegraded cellulose was extd. from cacao and the detn. required less than 1 hr
C. R. FELLERS

Determination of sulfur dioxide in foods containing sulfur-bearing volatile oils. FRANK A. DIBELLO. *Am. J. Pharm.* **103**, 42–4(1931).—The following method was used for detg. the SO_2 content of prepd. horse-radish and prepd. mustard to which had been added 150 p. p. m. of SO_2: To 54 g. of the material in a 500-cc. flask add 200 cc. water, 5 cc. 10% H_3PO_4 and about 0.5 g. of tannin. Distil slowly in a current of CO_2 until 100 cc. is received in 20 cc. of soln. of H_2O_2. Det. sulfates with $BaCl_2$.
W. G. GAESSLER

Mineral content of pastures research. Some notes on the work in 1929–30. B. C. ASTON. *New Zealand J. Agr.* **41**, 10–7, 90–9(1930).—An extensive investigation of the mineral content of N. Z. pasture grasses is being made in order to det., if possible, whether there is any relation between mineral deficiencies and various animal diseases which occur in specific areas. "Dopiness" in sheep seems to be connected with Ca deficiency in the Mairoa district, and it seems to be definitely established that "bush sickness" in cattle and sheep is caused by a deficiency of Fe in the pasture grasses of certain pumice soil areas. Deficiencies of I and P have been established in several localities Numerous analyses of N. Z pasture grasses are tabulated. K. D. J.

Investigations into the intensive system of grassland management. I. The chemical composition of intensively treated pasture. A. W. GREENHILL. *J. Agr. Sci.* **20**, 573–86(1930).—The chem. compn. of the dry matter of herbage from pastures managed under the intensive system and representing 3–5 weeks' growth was closely comparable with that obtained by other workers from "pasture cuts" at 1- to 3-weekly intervals from unfertilized pastures. The dry matter is a concd feeding stuff of narrow nutritive ratio and low fiber content. The nutritive ratio is somewhat wider in a dry than in a wet season, but the av. fiber content is not markedly different. During the grazing season, drought or the early summer flush period produces some reduction in protein content and an increase in fiber content, with a recovery following cessation of the drought or the flush period These variations are a reflection of the productivity and habit of growth of the herbage. An abundant growth of young leafy herbage has a higher nutritive value, wt. for wt. of dry matter, than the more stemmy growth of early summer or drought conditions. The protein content of the dry matter of herbage from pasture intensively fertilized (including N) was higher than that from untreated pastures. The higher milk-producing power of the former pasture may be ascribed to improved compn., as well as to higher yield, of the herbage. P. R. DAWSON

Nutritive value of pasture. VI. The utilization by sheep of mineral-deficient herbage. H. E. WOODMAN AND R. E. EVANS. *J. Agr. Sci.* **20**, 587–617(1930); cf. *C. A.* **24**, 5893.—A detailed study was made of the utilization by sheep of a sample of herbage deficient in total ash, particularly in respect to Ca and P_2O_5. Na was also low, but the percentages of K, Mg and Cl were similar to those of "normal" herbage. The results lead to the belief that the failure of stock to thrive on mineral-deficient pasturage cannot be explained by assuming that the low mineral content is responsible for lack of palatability and a consequent depression of appetite. There is no evidence that the shortage of minerals causes the herbage to be digested any less efficiently than "normal" cultivated herbage of similar maturity and org. compn. Malnutrition on pasturage of subnormal mineral content is due directly to failure of the diet to supply the necessary inorg. materials for constructional purposes and for maintaining the normal balance of minerals in the blood and tissues P. R. DAWSON

Photography as a help in the examination of cattle foods. W. L. FIELDING AND S. T. PARKINSON. *J. South-Eastern Agr. Coll., Wye, Kent* No. **27**, 45–73(1930); cf. *C. A.* **24**, 3575.—Detailed directions are given for the microscopical identification of leguminous plants and oil seeds in cattle foods. K. D. JACOB

Determination of acids in silage by Wiegner's method. K. GREIST. *Tierernähr.* **1**, 65–9(1929).—A diagram permitting direct reading of the amts. of AcOH and butyric acid has been constructed. B. C. A.

Polarimetric determination of starch in potatoes and the relation between potato dry substance and starch content (VON SCHEELE) **28. Composition [for treating containers for food]** (Brit. pat. 335,559) **23. Emulsions of fatty substances [artificial cream]** (Fr. pat. 693,242) **13.**

Food products. ARMAND KREMPF. Fr. 692,918, June 27, 1929. Proteic substances (fish, seeds, vegetables) are autolyzed rapidly in the presence of volatile antiseptics which do not entirely prevent microbic or fermentative action, the antiseptic is removed and the autolyzate is seeded with one or more appropriate cultures and the cultures are allowed to develop. The product is stabilized with NaCl and used as a food.

Stabilization of nitrosylsulfuric acid for bleaching flour. N. V. MEELFABRIEKEN DER NEDERLANDSCHE BAKKERIJ and CHEMISCHE INDUSTRIE VAN HASSELT. Dutch 23,063, Nov. 15, 1930. The $ONOSO_3H$ is mixed with 1/4 part active silicic acid or kieselguhr. Cf. *C. A.* **24**, 4559.

Evaporating apparatus suitable for condensed milk production. ARNOLD W. BAUMANN. U. S. 1,791,262, Feb. 3. Structural features.

Plastic cream product. HERMAN D. WENDT (to Sharples Separator Co.). U. S. 1,791,068, Feb. 3. Cream is warmed to render the milk fat fluid without destroying the integrity of the fat particles and the original emulsion holding them in dispersed phase, and sufficient liquid is then removed by centrifuging so that the remainder on cooling forms a plastic mass of dispersed milk fat particles. U.S. 1,791,069 relates to the production of *butter* from a plastic cream product contg. not less than 65% of milk fat held in natural dispersed condition with other constituents of milk, by reversing the phase relation of the milk fat globules to the liquid vehicle by pressure applied directly to the plastic cream for transforming the latter into butter, removing a substantial portion of liquid vehicle from the mass as it is formed, and continuing the application of pressure to the butter until the desired texture is obtained.

Butter production. EDGAR PERKS. U. S. 1,791,000, Feb. 3. A stream of cream is subjected to repeated impact through vibratory motion imparted to the steam in a direction perpendicular to its surface. App. is described.

Preserving eggs and fruits by vacuum treatment and coating with petroleum oil or wax. L. BENOIT. Brit. 335,586, March 27, 1929. The coating material is applied in heated vaporous condition (as by steam distn.) to the materials treated while the latter are subjected to a partial vacuum. App. and various details of procedure are described.

Preserving fruit. KARL HESSEL. Ger. 515,160, May 5, 1926. In preserving fruit by drying in air at a low temp. and then comminuting and pressing, air is removed from within the comminuted fruit by suction.

13—GENERAL INDUSTRIAL CHEMISTRY

Woods for insulation. A. R. DUNTON. *Electrician* **106**, 237–9(1931).—The varieties used, methods of impregnation and breakdown voltages of treated woods are discussed. Typical phys. properties of the varieties of hard wood employed in insulation are tabulated, as are typical values of moisture content and elec. strength for various woods The woods are kiln-dried to a moisture content not exceeding 6%. Tables also show: some woods used for bakelized veneer-ply construction with typical tensile-strength values of products; compression-strength test results on these, and a comparison of elec. strengths of untreated and bakelized veneer-ply. The reliability of performance of all treated woods depends on their ability to withstand the penetration of moisture and it is therefore likely that thoroughly bakelized woods, impregnated in the form of thin veneers and built up into rods or boards, will prove popular. Adsorption of gases. SOC. CHIM. DE LA GRANDE PAROISSE (AZOTE ET PRODUITS CHIM.). Fr. 693,278, June 17, 1929. In a process for sepg. less volatile constituents

of a gas by solid adsorbent material, the gas is passed through the adsorbent under pressure and then expanded, and the expansion is used through a heat exchanger to cool the gases being treated.

Separating mixtures of gases or vapors. Soc. de recherches et d'exploitations pétrolifères. Ger. 515,296, June 8, 1926. Mixts. of gases or vapors are passed through active C or other adsorbent and the adsorbed constituents recovered by means of steam after preheating the charged adsorbent. The improvement consists in preheating the adsorbent convectively, *e. g.*, by locally heating the adsorption app. so as to effect a circulation of the gases therein. App. is shown.

Separating gases by liquefaction. Ges. für Linde's Eismaschinen A.-G., F. Pollitzer and H. Kahle. Brit. 335,599, June 26, 1929. Various details of app. and procedure are described, suitable for the sepn. of constituents of purified coke-oven gas. Cf. *C. A.* **24**, 2515.

Separating gas mixtures by liquefaction. Société l'air liquide (Soc. anon. pour l'étude et l'exploitation des Procédés Georges Claude). Ger. 513,682, Dec. 1, 1929. Addn. to 495,429. In the method of Ger. 495,429 (*C. A.* **24**, 3292), the cold unliquefied compressed residue is further cooled before it is caused to flow countercurrent to the mixt. Cooling may be effected by the expanded residue. The app is shown.

Purifying liquefied gases. N. V. Philips' Gloeilampenfabrieken. Fr. 692,621, Mar. 24, 1930. Liquefied gases such as O are purified by bringing them in contact with an absorbent material such as charcoal or SiO_2 gel.

Deoxygenating air, etc. Siemens-Schuckertwerke A.-G. Ger. 515,133, Dec. 23, 1924. A mixt. of a metal and an electrolyte is used such that the metal, under the action of O, is converted into an oxidizable salt. A mixt. of Cu and NH_4Cl is specified. Catalysts, *e. g.*, kieselguhr or active C, and diluents may be included in the mixt. The method is intended particularly for eliminating O above the oil level of oil-filled elec transformers, switches, etc

Separation of solutions from precipitates. H. Lawarrée. Belg. 371,194, July 31, 1930. An immiscible liquid, inert toward the reagents used or liberated, and having a different d. from that of the solns. involved, is used for the sepn. of solns. and ppts.; *e. g.*, CCl_4 is used for the sepn. of the solns. in the manuf. of $NaNO_3$ and NH_4Cl from NaCl.

The separation of chemical solutions and precipitates. H. Lawarrée. Belg. 371,586, Aug. 31, 1930. Solns. are sepd. from ppts. by means of a liquid which is inert toward the reagents used or liberated, immiscible with them and of different d. A fatty substance which can form a soap with the basic salts pptd. during the reactions is added to the liquid.

Aerating liquids. Eugen G. Stich. Ger. 507,294, Jan. 5, 1929. The air is delivered through perforated tubes encased in rubber, the latter having fine perforations which open only under the pressure of the air supplied.

Testing viscosity of liquid materials. Samuel T. Rodgers. U. S. 1,790,948, Feb. 3 A buoyant body is released at the bottom of a column of the liquid under test, permitted to rise through the liquid and the time required for its rise is noted. App. is described.

Obtaining pulverulent products from fused solids. Chem. Fab. von Heyden A.-G. (Ernst Krumbiegel, inventor). Ger. 514,419, Mar 2, 1928. The solid is heated and stirred in a pressure vessel with a liquid in which it is difficultly sol. to a temp. above the m. p. of the solid and above the b. p of the liquid. The mixt. is then discharged into a second vessel in which it is rapidly cooled by contact with a further amt. of liquid kept in rapid motion. Examples describing the treatment of β-naphthylamine and benzonaphthol are given.

Emulsions of fatty substances. Botulf Borthen. Fr. 693,242, April 3, 1930. Artificial cream and other emulsions rich in fatty substances are made by using concd. milk or other natural concd. soln. of phosphoprotein as protective colloid.

Electric insulators. Lodge-Cottrell, Ltd., and Metallges. A.-G. Brit. 335,503, Feb. 18, 1930. For preventing moisture condensation on insulators such as those of *elec. gas-cleaning app.*, the insulator is heated from a suitable source of heat by a reflector which may be revolved around the insulator (suitably with transmission of the heat through ordinary or quartz glass).

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Liège water service (1830–1930). E. THIRIAR. *Tech. sanit. munic.* **25**, 370–5 (1930).—An historical account. W. C. R. FELLERS

Kankakee (Ill.) served by new plant. GEO. HUSE. *Water Works Eng.* **83**, 498 (1930).—The new electrically equipped plant has a capacity of 6 million gals. daily while the present rate of consumption is 2 million gals. daily. River water is softened, clarified, carbonized, allowed to settle, filtered and made bacteriologically pure. Soda ash and lime reduce the hardness from an av. of 20 grains to about 4 or 5 grains per gal. The av. cost of chemicals will be about $2000 a month. C. H. BADGER

How North Carolina develops its water works plant operators. H. E. MILLER. *Water Works Eng.* **83**, 423–4, 446–9(1930).—The different acts and laws passed in N. C. pertaining to sanitation and water supplies are reviewed. Inexperienced but technically trained chemists and engineers are secured through the Bureau of Engineering for duty at small plants at a salary of $125 a month. Under the guidance of trained engineers these men are given thorough training in plant operation, serving a sort of internship for 2 yrs., until they can assume responsibility. In 1921 none of the 18 surface gravity supplies was chlorinated but in 1929, 19 out of 20 were. All filtered water supplies are now chlorinated. In 1921, 50 filter plants were deficient, 36 being obsolete, 10 requiring complete overhauling and 4 needing minor repairs. In 1929 all except 2 of the 78 filter plants were fully meeting modern practice. Only 1 plant was under technical supervision in 1921 while in 1929, 57 plants had complete chem. and bacteriol. control at the plant and 17 had simple lab. control of dosage. C. H. BADGER

A limnological significance of free carbonic acid. E. LINDEMANN. *Naturwissenschaften* **18**, 1113(1930).—Evidence is advanced for the importance of the CO_2 content of water for the growth of *Peridinia* provided the p_H is favorable. B. J. C. v. d. H.

Deciding type and layout for a small water system. G. B. LEONARD. *Water Works Eng.* **83**, 513(1930).—The water works and the sewerage system in Salisbury, Md., became inadequate in 1924. Investigations of surface and ground supplies showed that shallow wells on low ground produced the only supply worth developing. Six concrete wells have been constructed on the site selected and the Schumaker pond, nearby, can be used as an emergency supply. Aeration, to remove CO_2, is the only treatment necessary for this water. The water works system is based on an av. daily consumption of 100 gal. per capita. The general layout of the distribution is described. Two pumping operations were required, a low service from the wells to the aerators superimposed over the 500,000 gal. covered concrete storage reservoir, and the other from the reservoir to the mains and to the two 200,000 gal. elevated storage tanks situated in opposite ends of the town. Elec. power is used. C. H. BADGER

Utilizing marine gasoline engine as a water works (Oshawa, Canada) auxiliary unit. W. C. SMITH. *Water Works Eng.* **83**, 489–90, 522(1930).—A detailed description is given of a unique installation used as a standby unit on auxiliary standby plant for a water works system suppling 2 million gals. daily. C. H. BADGER

Building efficiency into an old purification plant. MARTIN E. FLENTJE AND CLARK CRAMER. *Water Works Eng.* **83**, 421–2, 450(1930).—The reservoir capacity at Lexington, Ky., is 1765 million gals. The water shed area is 12.7 sq. miles. There are 10 wooden tub filters and 2 concrete units with a total rated capacity of 6.325 million gals. daily. Eight addnl. 1 million gals. daily concrete units will be constructed. The reservoir water is fairly constant in chem. compn. and has an av. hardness of 110 p. p. m. The bacteria count is low because of long storage and absence of polluting sources. Microörganisms grow abundantly in the shallow reservoirs in the summer and $CuSO_4$ treatment is given at least once a week. The sand in the wooden tub filters became badly incrusted because of lack of proper washing facilities. Cleaning with NaOH, Na_2CO_3, Cl_2 and $CuSO_4$ solns. was not effective. Since lab. expts. showed that some form of abrasion is necessary for cleaning, the sand will be treated with 2% caustic soln. for 24–48 hrs.; it should be agitated every 2 hrs. with air piped into the underdrain system. Four samples thus far collected monthly show progressive darkening and lack of luster. The portion sol. in HCl and the loss on ignition have increased. Whether bad incrustation will be prevented remains to be seen. C. H. BADGER

Design and construction of additional filter units. HUGH R. CRAMER AND ARTHUR T. CLARK. *Water Works Eng.* **83**, 450–4(1930).—The new filter units mentioned (cf. preceding abstr.) are of the general type. Addnl. features are the combining of

the filter effluents, wash water, air wash and rewash through a special fitting. Their construction and operation are described in detail. C. H. BADGER

Building small purification plant at a minimum cost in restricted area. M. P. HATCHER. *Water Works Eng.* **83**, 487–8, 525(1930).—The water supply for Iola, Kan., is obtained from the Neosho River. This river carries much suspended matter and is subject to considerable pollution from a well-populated drainage area of 3600 sq. miles above Iola. About 50 to 75% of the hardness of 100–500 p. p. m. is due to $Ca(HCO_3)_2$. Chlorides are usually less than 400 p. p. m. but during low flow periods they run 500–700 p. p. m. because of oil field pollution. The present treatment includes only plain sedimentation and chlorination. In the new treatment plant, built on the same site, the raw water is to be pumped to a preliminary mixing chamber where lime will be added. The treated water, kept at a high velocity to prevent settling, will then pass to 2 similar reaction tanks for 30 min. agitation with a centrifugal pump and in turn passes to either or both of a 2.5 million gal. and a 3.5 million gal. settling basins for a max. retention period of 3 days. The water is then pumped to the aerator and carbonating chamber. Alum is dry fed to the suction of the auxiliary low service pumps. The reaction proceeds through the carbonating chamber and the alum reaction chamber but the major portion of the floc will be carried to the 3 filter beds, each with a capacity of 2/3 million gal. daily. The filtered water passes in turn through the storage reservoirs situated below the filters, the secondary basins and the pump room. Total storage capacity is 215,000 gal. Cl_2 is applied at the entrance of the last reservoir. C. H. BADGER

Controlling microscopic organisms in public water supplies. FRANK E. HALE. *Water Works Eng.* **83**, 353–4, 379–84(1930).—See *C. A.* **25**, 367. C. H. BADGER

Fluorescence of water in filtered ultra-violet light as an indicator of pollution. H. IVEKOVIC. *Z. Hyg. Infektionskrankh.* 112, 54–61(1931).—The fluorescence of drinking waters was examd. in the light from a quartz lamp passing through a black glass filter of NiO, and compared with gelatin standards. Many waters showed a bluish white fluorescence whose intensity was proportional to the consumption of MnO_4^-. The org. matter present is considered the cause of the fluorescence. R. B.

Unusual bacterial conditions encountered at the Williamson filtration plant. PAUL C. LAUX. *Proc. 5th Ann. Conference on Water Purification*, W. Va. Univ. Eng. Expt. Sta., *Tech. Bull.* No. 3, 40–8(1930); *U. S. Pub. Health Eng. Abstracts* **10**, W, 115(Oct. 25, 1930).—Bacterial tests on 5 ten-cc samples are made daily at the filtration plant. Of 5040 samples of filtered water, 85% gave neg. gas production after 48 hrs. Four types of gas-forming bacteria are described which produce gas but which are not fecal coli. They are thought to originate in the soil or in animal or human feces. Excess chlorination and preammoniation have but little effect on these gas-forming bacteria. C. R. FELLERS

Use of pre-ammoniation at the Springfield, Ill. plant. CHARLES H. SPAULDING. *Water Works Eng.* **83**, 514–8(1930).—The bacterial loads in the raw water have been excessively heavy. Tabulations of lab. expts. using added cultures of *B. coli* with river water show that sterilization with 1 hr contact was greater when NH_4OH was added just before chlorination but were less satisfactory even with a contact period up to 6 hrs. when lime was also added. After 8 hrs. contact chlorinated samples, with or without lime and NH_4OH, showed practically the same percentage reduction of *B. coli*. Lime by itself is slow in comparison. River water contg. 1.2 p. p. b phenol is sufficient to cause a chlorophenol taste but NH_4OH added in the portion of $^1/_2$ lb. NH_4OH to 1 lb. Cl_2 prevented chlorophenol tastes in boiled distd. water contg. 2 to 50 p. p. b. phenol and lime to a p_H of 9.6. The packing of the high-service pump showed *B. aerogenes* present; estd. at 20 billion per lb. NH_4OH is now added at the rate of 0.7 lb. per million gal. of water at the inlet of the raw water dosing well where the detention is about 30 sec. and Cl_2 is applied at the outlet of the dosing well. The residual Cl_2 as a rule drops by the time the water has passed the filters and about 1 lb. Cl_2 per million gal. of water is sufficient to bring the residual Cl_2 up to 0.2–0.3 p. p. m. Aqua NH_4OH and anhyd. NH_4OH were less expensive to use than NH_4OH salts. C. H. BADGER

Unusual uses of chlorine in a water works system. (Sterilization of new mains, new wells and flooded supplies.) R. W. KEHR. *Water Works Eng.* **83**, 458–61(1930).—K. cites the procedures for sterilization by Cl_2 of mains, etc., in New York, Chicago and Indianapolis. The sterilization of newly laid mains in Kansas has not received much attention. The av. time for 9 new supplies to become free from contamination was $6^1/_2$ months. Gravel used for gravel wells should be thoroughly treated with chlorinated lime water. All turbidity should be pumped from newly constructed wells. Residual Cl_2 was soon shown by the *o*-tolidine test when chlorinators fed several

p. p. m. Cl_2 to flooded supplies in Ottawa, Augusta and Eldorado. The following directions are given for sterilizing small quantities of water. Make a soln. of 1 teaspoonful of chlorinated lime in a pint of water, stir 1 tablespoonful of this stock soln. into 10 gal. of water and let stand 30 min. With very muddy waters double the dose. To clarify muddy waters add 1 teaspoonful alum to 5 gal. of water. After mixing and settling, the decanted water is sterilized. Boiling the drinking water was found to be impracticable during the Mississippi flood and Cl_2 sterilization was used almost entirely.
C. H. BADGER

Problems of slow chemical reaction in cold weather. C. T. HOUGH. *Water Works Eng.* **83**, 510(1930).—Lawrence, Kan. obtains its water supply from the Kaw River. The treatment includes plain settling, coagulation, softening, chlorination and filtration. Alky. varies from 125 p. p. m. in summer to 300 p. p. m. in winter and sulfate hardness likewise varies 60 to 125 p. p. m. The slow reaction of lime in cold water produced the same effect as a reduced retention period in the basins. Settling was not complete even when a dosage of 0.7 grain $Al_2(SO_4)_3$ per gal. was applied to the lime basin influent, necessitating a large amt. of wash water for the roughing filters. Attempts during low temp. to lower the alky. to 50 p. p. m. resulted in high carbonates and a heavy ppt. on the final filters, which showed on analysis nearly 50% $Al(OH)_3$ and the remainder $CaCO_3$ and $MgCO_3$. This ppt. is probably due to the retarded reaction of $Al_2(SO_4)_3$ with a highly lime-treated water. Reducing the lime treatment, thereby increasing the alky. to 70–80 p. p. m., eliminated a large amt of the ppt. and permitted satisfactory filter operation. In Dec., 1926 bacteriol. analyses, even with daily increased Cl_2 dosage, began to show pos. tests for the coli-aerogenes group in the first $1^1/_2$ miles of mains from the plant, but beyond this distance were neg. This indicated that the reaction of Cl_2 in water at 38–40°F. is slow and that there must be a sufficient contact period before distribution. After unsuccessful results of applying addnl. Cl_2 to the filter influent, $2^1/_2$ lb. per million gal. of water was then added to the lime basin influent and bacterial analyses showed neg. results. More recent attempts during low temps. to increase the lime dosage to give an alky. of 60–70 p. p. m. caused pos. bacterial results immediately. It is evident that increasing the p_H value of the treated water decreases the effectiveness of Cl_2.
C. H. BADGER

Use of permanganate at the Weirton, W. Va., city water works for the correction of chlorophenol tastes. L. L. LASHELL. *Proc. 5th Ann. Conference on Water Purification*, W. Va. Univ. Eng. Expt. Sta., *Tech. Bull.* No. **3**, 37–9(1930); *U. S. Pub. Health Eng. Abstracts* **10**, W, 116(Oct. 25, 1930) —$KMnO_4$, 1.45 p. p. m., applied between the sedimentation basin and filters, was entirely successful in removing the phenol tastes and odors and its bactericidal effect was great enough to warrant discontinuance of chlorination.
C. R. FELLERS

Operating results from well-arranged iron removal plant. C. C. FOUTZ. *Water Works Eng.* **83**, 557–8(1930); cf. *C. A.* **24**, 5902.

Arsenic content of the Choussy well water, La Bourboule, and fixation of this arsenic in the organism. R. CLOGNE, (MLLE.) A. COURTOIS AND CAZALA. *Compt. rend.* **190**, 1133–4(1930).— Arsenic was detd. by a modification of the Cribier-Léonardon method, the stain on the $HgCl_2$ paper being fixed by immersion in a 10% soln. of KI and matched against standard stains prepd. under the same conditions. A slight excess of $KMnO_4$ was added to the sample to avoid evolution of H_2S or PH_3. Arsenic contents of 5.8–6.5 mg. per l. are recorded for the season 1928–29, and analyses of tadpoles kept in the water at the well for 8–10 days showed As contents of 3.25×10^{-3} mg. of As per g. (1.88×10^{-3} mg. per g. in ordinary water) Tadpoles in bottled Choussy water, or in synthetic water of similar compn., contained only 2.73 and 2.325×10^{-3} mg. per g., resp.
B. C. A.

Determination of silicic acid in water. W. STEFFENS. *Chem.-Ztg.* **54**, 996–7 (1930).—The colorimetric method depending on the formation of a yellow silicomolybdate is described again, preference being given to K_2CrO_4 solns. rather than picric acid solns. as standards of color.
W. T. H.

Determination of the "chlorinity" of ocean waters. THOMAS G. THOMPSON AND RICHARD VAN CLEVE. Intern. Fisheries Commission, Univ. Wash. (Seattle), *Report* No. **3**, 5–14(1930).—An outline is given of the literature dealing with factors that may produce possible variations between the calcd. and detd. densities. Modifications of Mohr's method, which differ as to type of volumetric app. used, size of sample and concn. of $AgNO_3$ soln. all give practically the same results. Errors in direct d. detns. were found to result from permitting an elapse of time between collection and analysis of the samples. The detn. of "chlorinity" gives the best method for the calcn. of the

most probably d. *in situ* at atm. pressure A table is given for converting "chlorinity" per l. to "chlorinity" per kg. at 20°. C. R. FELLERS

Determining protection of underground pipe through proper survey. P. J. RICHARDS. *Water Works Eng.* **83**, 491–2, 525(1930).—Chem. analyses of the soil and waters or aq. ext. of soil samples taken as required by means of an auger from the surface down to the bottom of the ditch will show the presence and the amt. of all chemicals known to be corrosive, non-corrosive, accelerators or inhibitors of corrosion. The phys. characteristics of the soil affect the rate of percolation of soil waters and will det. the character of the contact between the metal and surrounding materials. Heterogeneity of soils may lead to differences in potential within the soil itself and also between the soil and the buried material. Differences in potential will probably accelerate corrosion proportionate to the current flow. This knowledge will det. whether the pipe will serve without protection or whether an expensive coating is justified. Corrosion surveys have been made in Denver and Pueblo for the use of gas-distributing systems. Strong alkalies are usually destructive Chlorides and sulfates seem to be the most harmful. Sulfides are potentially dangerous and all soil acids must be considered corrosive. Limestone is not only non-corrosive but seems to be an inhibitor when corrosive chemicals are present Coatings must be thick enough to protect the metal and wrapped coatings must be used where there may be severe abrasion. It has been estd. that over half of the coatings that have been applied to pipe lines might have been saved if some knowledge of the corrosiveness of the locations had been obtained beforehand and that half of the remainder was either misapplied or underprotected. C. H. B.

The corrosion-checking calcium carbonate-protective layers in water tubes. GERHARD SCHIKORR. *Z. angew. Chem.* **44**, 40–1(1931).—The resistance of iron water tubes to rusting is very strongly increased through a $CaCO_3$-protective layer. For the formation of the layer, a definite quantity of O must be dissolved in the water. The water must contain a sufficient quantity of dissolved $CaCO_3$ but must not contain too great an excess of H_2CO_3. The action of the O may be traced to an electrochem. effect in contrast to the theory of Tillmans, Hirsen and Schilling (*C. A.* **23**, 1973). In order to show that the formation of the protective layer is not the result of the adsorption of H_2CO_3 by $Fe(OH)_3$ but is a cathode reaction, a noble metal was used in place of Fe. Expts. indicate that with suitable arrangements $CaCO_3$ can be pptd. from a $Ca(HCO_3)_2$ soln. on Pt with the aid of O. ALLEN S. SMITH

The continuous control of the salt content of boiler-feed water by means of a visual conductivity measurement. E. ROTHER AND G. JANDER. *Z. angew. Chem.* **43**, 952–4 (1930).—The chloride content of feed water is detd. by leading the water through a specially designed tube contg. Pt electrodes. The detns. are continuously recorded potentiometrically. RUSSELL C. ERB

Problems of a watershed sanitary inspector. S. F. GLASS. *Water Works Eng.* **83**, 376 (1930).—Rural sewage-disposal problems and the disposition of dead animals in the Denver, Col., watershed area are briefly discussed. C. H. BADGER

Performance of the Tenafly (N. J.) activated sludge plant. WILLEM RUDOLFS, H. HEUKELEKIAN, I. O. LACY AND C. N. HENDERSON. N. J. Agr. Expt. Sta., *Bull.* **502**, *Ann. Rept. Dept. Sewage Disposal* **1928–9**, 12–7(1930).—Chem. and bacteriol. examns. made on the Tenafly activated sludge plant and covering a period of 36 hours' sampling show that a high degree of purification and clarification was obtained. The av. biochem. O demand reduction was 93.5% and the *B. coli* reduction % was 99.99. C. R. FELLERS

Some operating results of the Plainfield (N. J.) disposal plant. WILLEM RUDOLFS AND I. O. LACY. N. J. Agr. Expt. Sta., *Bull.* **502**, *Ann. Rept. Dept. Sewage Disposal* **1928–9**, 9–12(1930).—In spite of the staleness of the sewage and the comparatively short detention time, the settling tanks removed 53% of the total suspended solids in addn. to 9–12% suspended solids removed by fine screens. The screened sewage averaged 737 p. p. m. total solids, 256 p. p. m. suspended solids and 190 p. p. m. biochem. O demand. Total reduction in biochem. O demand for the settling tanks and sprinkling filters was 56.2%, $^3/_4$ of which was taken care of in the sprinkling filters. C. R. FELLERS

Effect of certain chemicals on the vacuum filtration and gravity drying of ripe sludge. WM. H. BAUMGARTNER. N. J. Agr. Expt. Sta., *Bull.* **502**, *Ann. Rept. Dept. Sewage Disposal* **1928–9**, 17–25(1930).—$FeCl_3$ was the most effective treating chemical for ripe sludge. $FeCl_3$ has a 3-fold effect in sludge drying and filtration: (1) discharge of the dispersed material, coalescence being caused; (2) change of the H-ion concn., the isoelec. points where max. pptn. of the colloidal material takes place being thus approached; (3) liberation of CO_2, which makes the material porous and helps

in its flotation. There are peaks in the filtration of $FeCl_3$-treated sludge which correspond to definite p_H values. These peaks are at a concn. of 2 and 7 lb. to the cu. yd. of sludge, resp., $FeCl_3$ increases the amt. of drainage from sludge drying on beds and thus decreases the time for evapn. Treated sludge has a porous nature which allows more surface for evapn. Moisture is removed more rapidly by treating sludge with $FeCl_3$. C. R. FELLERS

Certain organic constituents of fresh and ripe sewage sludge. H. HEUKELEKIAN. N. J. Agr. Expt. Sta., *Bull.* 502, *Ann. Rept. Dept. Sewage Disposal* 1928–9, 31–6(1930).—The most abundant constituents of the org. matter of fresh solids are fats and crude proteins. Materials present in smaller percentages are water-sol. and alc.-sol. substances, hemicellulose, cellulose and lignin. Fats and cellulose show the greatest decrease in ripe sludge. Resistant substances like waxes and lignin are not decompd. readily and are therefore present in the ripe sludge in larger percentage than in fresh sludge. C. R. FELLERS

Notes on drying fresh sewage solids. ANTHONY J. FISCHER. N. J. Agr. Expt. Sta., *Bull.* 502, *Ann. Rept. Dept. Sewage Disposal* 1928–9, 29–31(1930).—Drying of fresh solids in the open is not feasible when treated with lime, alum, or a mixt. of lime and alum on account of poor drainage, objectionable odors, or both. C. R. FELLERS

Sludge drying. Relation between drainage and evaporation. WILLEM RUDOLFS AND I. O. LACY. N. J. Agr. Expt. Sta., *Bull.* 502, *Ann. Rept. Dept. Sewage Disposal* 1928–9, 26–9(1930).—Studies dealing with the relation between drainage and evapn. of drying sludge indicate that up to a temp. of 130°F., drainage is a more important factor than evapn. The percentage of total moisture removed, resp., by drainage and by evapn. at various temps. are: 43°F., 94 and 6; 74°, 86 and 14; 100°, 77 and 23; 113°, 60 and 40; and 131°, 47 and 53. The practice of covering sludge beds with greenhouses is beneficial because rain is thus kept off the beds. C. R. FELLERS

Notes on stabilization in a sprinkling filter. WILLEM RUDOLFS. N. J. Agr. Expt. Sta., *Bull.* 502, *Ann. Rept. Dept. Sewage Disposal* 1928–9, 37.—A summary of chem. results shows the amts. of suspended solids, O consumed, NH_3, NO_2, NO_3, suspended org. N, and sol. org. N present at different depths of the filter beds. In general, the removal of NH_3 nitrogen is well correlated with the reduction on O-consumed values. NO_2 and NO_3 values are the only ones which increase with depth. C. R. FELLERS

Determination of p_H in the estimation of the productivity of carp ponds. LOUIS ROULE. *Compt.-rend. acad. agr. France* 16, 1056–60(1930).—The p_H of the water should be between 6 and 8 and care must be taken to maintain the water within these values. Tests and adjustments of the water should always be made early in the morning and in the shade, as sunlight has a very marked effect on the chem. reactions taking place. J. R. ADAMS

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER AND M. S. ANDERSON

Soils of Connecticut. M. F. MORGAN. Conn. Agr. Expt. Sta., *Bull.* **320**, 829–911 (1930).—The ratio of N to org. matter (av. of 100 soils) is 1:20. No serious decline in N content has occurred in the cultivated soils of Conn. during the last 200 yrs. The av. N content of 21 forest soils is 0.205%, which is practically identical with the av. for agricultural soils. The av. percentage of P in the surface 8 in. of Conn. soils is 0.0919, an insufficient amt. for the profitable growing of most farm crops. The availability of the P in many of the soils is very low. K varies from 1.3 to 2.6% on cultivated land with an av. of 1.4%. Nearly all soils respond to potash fertilizers and lime. The av. p_H of the soils is 5.3 and the lime requirement per acre approx. 1.3 tons. Numerous greenhouse expts. were conducted to det. the fertilizer requirements of the soils. C. R. FELLERS

The red soils and Bienhoa of Indochina. M. V. AGAFONOFF. *Soil Research* (Supp. to *Proc. Intern. Soc. Soil Sci.*) **2**, No. 2, 184–96(1930); cf. *C. A.* **24**, 2822.—The results of chem. and mineralogical studies on samples of soil from Indochina are reported. The soils differ from the basalt from which they are derived in the almost complete removal of Mg, gradual loss of Na, Ca and K, oxidation of FeO to Fe_2O_3 and content of twice the amt. of Al and Ti as the basalt. The alteration and formation of secondary minerals in the decompn. of basalt are described. The similarities between Bienhoa and laterite are pointed out. The sterility of certain soils could not be accounted for by deficiency of N, P_2O_5 and K_2O. Soils low in bases in general had poor structure. Data are reported on studies of the absorbing complex of the soils by the method of Gedroiz and on the amt. of SiO_2 and Al_2O_3 sol. in 5% KOH. I. A. D.

Adsorbed bases and unsaturation of Polish sandy soils. W. BUTOWSKI. *Rept. Polish Agr. Expt. Sta.* **2**, 195(1928).—The proportion of adsorbed bases in the soils examd. varied with their mech. compn. and increased with the clay content. The plant covering of forest soils increased the adsorbed bases in the upper horizons. The amt. of adsorbed bases was less in the B-horizon than in the surface but increased at still greater depths approaching the parent rock. Variations in the degree of unsatn. were parallel with those of the base content and were greatest in the loams. The genesis of the soils is discussed. Podsolization is considered to take place in these soils. B. C. A.

Soils and soil treatments in Quebec. R. R. MCKIBBIN. *Sci. Agr.* **11**, 361–8 (1931).—It is the final balance existing in the soil after the addn. of soil treatments that is important, rather than the use of balanced fertilizers. Sweeping conclusions that similar results may be obtained from the use of similar treatments on all light soils or on all heavy soils, are unwarranted. Fundamental soil conditions must be known before effective fertilizer practice can be established. A survey of Quebec's soils is given. C. R. FELLERS

Soils of Anatolia and eastern Thrace. F. GIESECKE. *Chem. Erde* **4**, 551–97(1930).—A description is given of the various types of soils, with partial mech. and chem. analyses. A soil map of Anatolia is given. B. C. A.

Nitrate fluctuations in a South Australian soil. J. A. PRESCOTT AND G. R. PIPER. *J. Agr. Sci.* **20**, 517–31(1930).—An investigation was conducted to det. the nature and importance of the fluctuations in the nitrate content of the soil during the season under typical conditions of cropping and fallowing. The rate of nitrification is governed primarily by the soil moisture conditions. During the characteristic summer drouth there is little evidence of change in nitrate, the quantities accumulated during the preceding period of activity remaining unchanged. The quantity of nitrate ac-

cumulated during fallowing, as observed over a succession of seasons, appears to approach a const. value of about 20 p. p. m. of the 1st 18 in. of soil, and the greater portion of this remains in the 1st few in. of cultivated soil, sometimes attaining a remarkably high level. It is not washed down until the advent of autumn rains. There is generally no leaching down below the root zone of the cereal crops. At certain periods of the winter the soil moisture may be sufficiently high to result in disappearance of nitrate, when present in quantity, from the surface soil. This depletion is not due to leaching, but possibly to an intake of nitrate by microörganisms. Toward the end of the spring, the rapid nitrate accumulation in the cultivated layer may be due to a possible capillary redistribution caused by rise from the lower layer, or to particularly favorable moisture conditions immediately below the surface of the mulch or in the lower layers of the mulch itself. During the biol. active period of the year the rate of nitrification under fallow conditions is appreciably more rapid than under a crop. Lab. investigations showed that nitrate accumulation was favored by a rather broad range of temp. conditions between 11° and 34°, with no sharp optimum temp. There was, however, a definite optimum moisture content (17%, calcd. on the moist soil), with a rapid fall on the wetter side, leading to nitrate depletion at moisture contents above 19%. Nitrate accumulation occurred with relatively dry soil, although more slowly than under optimum conditions. P. R. Dawson

The development of the soil profile in North Wales as illustrated by the character of the clay fraction. G. W. Robinson. *J. Agr. Sci.* **20**, 618-39(1930).—A study was made of the variations in compn. of the clay fraction in different horizons of some typical North Welsh soil profiles. The changes in the mol. ratio of SiO_2 to sesquioxides ($SiO_2/(Al_2O_3 + Fe_2O_3)$) throughout a soil profile afford an indication of the nature of the eluviation which has affected the mineral portion of the soil The data for the soils studied indicate a general tendency to enrichment of the lower layers in sesquioxides, particularly Fe_2O_3, at the expense of the surface layers. The SiO_2-sesquioxide ratio of the clay fraction is an important aid to series definition. The soils of North Wales, particularly in the uplands, have probably been subjected to considerable erosion in the past The profiles are therefore considered to be more or less truncated. The soil profile appears to be of the brown-earth type, with podsol development in the uplands under heath vegetation The importance of the parent material is emphasized. North Welsh soils are generally of a loam character. The absence of light sandy soils in situations permitting profile development precludes the occurrence of typical podsols in the lowlands. The high content of org matter, resulting from artificial grassland conditions, results in affinities with prairie soils. P. R Dawson

The physical and chemical characteristics of certain American peat profiles. Irvin C. Feustel and Horace G Byers. U. S Dept Agr., *Tech Bull.* **214**, 1 26(1930) Based on the data obtained from 38 peat samples, an attempt has been made to distinguish between the various types of peat according to botanical origin of peat material, certain phys. and chem. tests, and response to liming and fertilization. Methods, which in many cases are modified standard methods, are given for detg. the apparent and true sp. gr., moisture relations, max shrinkage, reactions, fractional analysis of org. matter, elementary and proximate compn., mineral constituents of the ash and behavior of certain samples submerged under anaerobic conditions. The max. moisture holding capacity and moisture equiv. are the most useful of the phys properties for peat classification. The most important of the chem. detns. are of the ether and alc fractions, hemicelluloses and cellulose, lignin-humus complexes, sol. and insol. N and ash compn. Differences in profiles often handicap differentiation of the various types. Sphagnum peat from Maine is of quite a different compn. from the other varieties examd., as it consists of stems and leaves of mosses and is less decomposed The North Carolina peat is distinct in that it shows the highest alc. solv. and lowest hemicellulose content. The Washington peat seems to be in an intermediate stage of decompn. The Me. peats have a high Al_2O_3:Fe_2O_3 ratio and are rich in alkalies. The Florida peats have a high CaO content, while the N. C. peats are low in CaO. The peats from the northern regions of the U. S. show marked differences from those of the southern states. J. R. Adams

Nutrient contents of Rhineland soils. G. Hager. *Landw. Z. Rheinprovinz* No. 47(1929).—A survey of Rhineland soils is recorded. The productivity of soils is not governed by the nutrient content alone, but is dependent on many other factors, notably the proportions of clay and humus, tilth, soil depth and climatic conditions. With due consideration of these factors, the Neubauer test (cf. *C. A.* **24**, 1453) gives valuable information as to soil fertility. B. C. A.

The potassium, chlorine and sulfate contents of Kentucky tobacco as related to

grade. O. M. SHEDD. Ky. Agr. Expt. Sta., *Research Bull.* **308**, 447–71(1930).—The samples were selected from the crops of 1920, 1921 and 1924. Large variations in certain mineral constituents were found in the 2 kinds of tobacco. The extremes for the Burley were 0.79 to 7.36% K, 0.02 to 1.50 Cl and 0.09 to 0.81 sulfate S, while for the dark they were 0.76 to 4.72 K, 0.04 to 2.99 Cl and 0.11 to 0.82 sulfate S. Those samples which had an unusually high chloride or sulfate content did not generally have an abnormal amt. of K. In 78% of the comparisons of the Burley tobacco and in 62% of the dark tobacco, more K was found in the good grades than in the common. In 58% of the comparisons of the Burley tobacco and in 48% of the dark tobacco, more Cl was in the good than in the common. In 64% of the comparisons of the Burley tobacco and in 63% of the dark tobacco, more sulfate S was found in the good than in the common. The Cl was the same in several comparisons, and the sulfate S in a few. If the 3 Burley crops are combined, the averages of the good grades show 24% more K, 31% more Cl and 4% more sulfate S than the common. A comparison of the Burley and dark crops of tobacco shows that the Burley carries 42% more K than the dark, whereas the latter has 196% more Cl and 11% more sulfate S than the Burley. More K was present in the smoker grades of Burley tobacco than in the filler grades. The K content of the different grades of Burley usually varied in proportion to market quality and price. The same relation existed between the K content, quality and value of the dark tobacco. Org. K predominated in the better grades of Burley. Furthermore, the smoker grades had more org. K than the fillers. Diseased leaves disturbed the usual percentages of K, Cl and sulfate S present in the leaves. The results indicate that in expts. where fertilizers contg. K are used on tobacco, particularly of the smoking types, observations should be made of the effects of different amts. and combinations of this constituent on the quality as well as the yield of the crop. Bibliography.

C. R. FELLERS

Impoverishment of forest soils by use of the litter. A. NĚMEC. *Forstarch.* **1929**, 497–503.—Low proportions of nutrients in many forest soils are attributed to the annual removal of mineral matter in the forest litter. In this respect the available potash is least affected. B. C. A.

"Single value" soil properties: a study of the significance of certain soil constants. V. On the changes produced in a soil by oven drying. J. R. H. COUTTS. *J. Agr. Sci.* **20**, 541–8(1930); cf. *C. A.* **25**, 159.—Results for the loss in wt. of a soil on oven heating can be obtained to a very satisfactory degree of accuracy by an electrically controlled oven. The results obtained by heating soils (brought to equil. with atm. at 50% relative humidity) to temps. ranging from 50° to 250° give smooth curves connecting loss in wt. with rise in temp.; they lead to the conclusion that there is no sudden alteration in the structure of a soil when it is heated to 100°. The air-dry moisture of a soil, as detd. with sufficient accuracy by the usual methods, is a convenient empirical factor, but not a representation of any fundamental soil property. Expts. show that the losses in wt. on oven drying are greater than are the regains in wt. when the dried samples are brought to equil. with an atm. of 50% relative humidity. As the drying temp. is raised, the recoverable loss changes but slightly, while the total loss increases rapidly. Strength is lent the supposition that the recoverable loss is due to removal of free and interstitial water, while the irrecoverable loss is due partly to water bound adsorptively or chemically by soil colloids and partly by the destruction of org. colloids. At any given temp. of drying both classes of losses play a role. There is no justification for assuming that there is any sharp line dividing one class of water from the other or that in any process one of the classes of water will be removed while the others are unaffected. P. R. DAWSON

The decomposition of urea in soils. T. GIBSON. *J. Agr. Sci.* **20**, 549–58(1930); cf. *C. A.* **24**, 4882.—Investigation of the decompn of urea in 59 soil samples of extremely varied character showed that the compd. was decompd. readily in all, and very rapidly in most, of the cases. In mountain and heath soils decompn. was generally active, especially in soil tests. Strongly acid peat samples (p_H 3.1–3.3) decompd. from 0.44 to 0.86% of their own dry wts. of urea in 24 hrs. at 22–23°. In soln. and soil tests samples from permanent pastures produced a more rapid decompn. than those from cultivated land. In soil tests as high as 1% of the dry wt. of soil was converted to NH_3 in 24 hrs. at 22–23°. Fertile arable soils produced a relatively slow decompn. in soil tests. Forest soils were generally more active than cultivated soils. Strongly alk soils showed comparatively little activity in soil tests, but greater activity in soln. tests. Although urea is not absorbed by soils, its rapid conversion to NH_3 will generally prevent losses by leaching. P. R. DAWSON

Parent material as a factor in soil formation and as a criterion in soil classification.

B. POLYNOV. *Soil Research* (Supp. to *Proc. Intern. Soc. Soil Sci.*) 2, No. 2, 165–77 (1930).—The "climatic soil type" is a very broad and general concept. Soils must be further subdivided according to the properties and compn. of the rocks from which they are formed, since various rocks differ widely in their influence on soil formation. I. A. DENISON

A study of the pedogenic processes in an area of lower paleozoic shales. G. H. GETHIN JONES. *J. South-Eastern Agr. Coll., Wye, Kent* No. 27, 229–47(1930).—A full account is given of a podsol soil occurring in North Wales. There is a definite acid leaching of the sesquioxides from the eluvial horizon, followed by their subsequent deposition in the illuvial horizon of accumulation immediately below. The nature and extent of some of the pedogenic processes are shown by partial and complete profile chem. analyses of the sedentary soil, down to and including the parent rock. Welsh upland soils are in general very unsatd. with respect to lime because of excessive acid leaching in a humid climate. These soils and parent rock contain a relatively high proportion of MgO, usually about 1%. In the podsolized regions the ratio of exchangeable CaO to org. matter increases with depth, despite the poorer soil dispersion at the lower levels. This shows leaching from the upper layers, without evidence of a CaO horizon of accumulation. A profile study of p_H values showed a continuous rise toward neutrality as the relative amt. of unsatd. org. matter decreased with depth. Soil analyses by 48-hr. HCl extn. do not give reliable information as to the abs. chem. compn. of soils differing in their mech. and chem compn. K. D. JACOB

The importance of rare elements in the nutrition of plants. O. C. BRYAN. *Proc. Assoc. Southern Agr. Workers, 31st Ann. Convention* 1930, 239–42.—A general discussion with particular reference to the use of Cu and Mn salts on the Florida Everglades soils. K. D. JACOB

Correlations between the specific conductivities of soil extracts, nitric nitrogen and soluble calcium. C. H. WRIGHT. *8th Ann. Bull. Agr. Dept., Nigeria* 1929, 104–9; cf. *C. A.* 25, 761.—Periodical sampling and analysis of cropped soils show that the Ca and nitrate contents of 1 5 soil-water exts. are closely correlated with their sp. conductivities. Increased cond. is evidence of biol. activity in the soil. B. C. A.

Report of the committee on soil reaction measurements. SECOND COMMISSION, INTERNAT. SOC. SOIL SCI. *Soil Research* (Supp. to *Proc. Intern. Soc. Soil Sci.*) 2, No. 2, 141–52(1930).—The committee has already published (*Soil Research* 2, 77–139 (1930)) the methods and results of its coöperative investigation on detn. of the p_H value of soils. With few exceptions, p_H values obtained by 4 independent methods showed satisfactory agreement. Of a total of 28 soils examd., 8 gave erroneous results by the quinhydrone method. It is recommended, therefore, that a preliminary detn. be made to ascertain whether the quinhydrone method is suitable for a given soil. Where the increase in apparent p_H value from 10 to 60 sec. is less then 0.2, the method may be considered suitable. The final measurement is made by shaking the soil and water 1 min., adding the quinhydron, shaking again for 10 sec. and measuring the potential after 1 min. In the case of soils considered unsuitable for an exact detn. of p_H by this method, an approx. detn. can be made on a new sample after 10 sec. In the detn. of p_H by the H electrode a sintered glass crucible or funnel is recommended. The colorimetric method did not always agree with electrometric methods, although satisfactory agreement can be obtained with great care. I. A. DENISON

The relation between p_H value and state of saturation of soils. AMAR N. PURI. *Soil Research* (Supp. to *Proc. Intern. Soc. Soil Sci.*) 2, No. 2, 181–4(1930).—The state of satn. of the soil (V) is defined as the ratio of the amt. of absorbed bases in the soil (S) to the amt. of bases the soil is capable of absorbing (T), both values being expressed in equivs. Thus $V = 100S/T$. The value ($T - S$) is detd. by adding 100 cc. 0.2 N $Ba(OH)_2$ to 10 g soil and 2 g. $CaSO_4$ and titrating after several days against 0.1 N H_2SO_4 with phenolphthalein as indicator. T is detd. by removing all replaceable bases from 10 g. soil with 0.05 N HCl, washing with water and titrating back after adding an excess of $Ba(OH)_2$ as described above. From the values ($T - S$) and T, the S and V values are calcd. A general relation between degree of satn. and p_H was noted in the case of 36 soils. The difference in the nature of the colloids present in different soils is shown by fact that the T value per g. of clay varies from 0.252 to 1.516. I. A. DENISON

Growing onions on the muck soils of New York. J. E. KNOTT. Cornell Univ. Agr. Expt. Sta., *Bull.* 510, 3–34(1930).—On muck soils that have been under cultivation less than 10 years, increased quantities of N gave a neg. correlation with yield. P had little effect, but a fair response to K was apparent. On new, slightly acid mucks,

1000 lb. of 0–12–18 fertilizer is recommended, while for more acid mucks the formula is changed to 3–12–18. C. R. FELLERS

Lysimeter experiments. III. Records for tanks 3 to 12 during the years 1910 to 1924 inclusive. T. L. LYON, J. A. BIZZELL, B. D. WILSON AND E. W. LELAND. Cornell Univ. Agr. Expt. Sta., *Memoir* **134**, 5–72(1930); cf. *C. A.* **16**, 1123.—The lysimeters are square concrete tanks with funnel-shaped bottoms, each contg. 3½ tons of Dunkirk silty-clay loam soil. About ⅔ of the av. 32.5-in. rainfall percolated through the uncropped tanks; somewhat less than ½ percolated through the cropped soils. About 18% of the water was transpired by the plants on cropped tanks. Applications of lime had no appreciable effect on the proportion of rainfall that percolated through the soil. Liming did not increase the total quantity of N in the drainage water from the tanks in which only non-legumes were grown, nor did it have any effect on the quantity of N in the crops grown on these tanks. In the tanks with legumes, lime produced a decided increase in N, both in the drainage water and in the crops. Where legumes were grown in assocn. with non-legumes, the quantities of N contained in the latter were nearly as large as when the non-legumes were grown alone, in spite of the space occupied by the legumes and the nutrients they removed from the soil. There was less tendency for the N produced in the crops to decrease from year to year when the rotation contained legumes, than when it did not. In the tanks where no legumes were grown, the drainage water alone of the unplanted tanks contained more N than did the drainage water and plants combined from the planted tanks. This is attributed to N-synthesizing organisms which thrive better in the org. matter derived from the plant roots. Tanks in continuous grass lost less N than those planted to non-legume crops. The quantity of Ca in the drainage water from the unplanted soil was greater than that in the combined crops and drainage water from the planted tanks. Because of this, an annual conservation of 144 lb. of Ca per acre was effected by cropping the soil instead of leaving it bare. The larger removal of Ca in the drainage water from the unplanted soil than from the planted tanks was due chiefly to the much greater quantity of nitrates leached from the unplanted soil. Liming the soil was not accompanied by an increase in the quantity of Ca in the drainage water or in that of the crops produced. Its loss was decreased by cropping. To replace the yearly loss of Ca from an acre of cropped land requires approx 560 lb. of $CaCO_3$. To recoup the loss from bare soil would require about 900 lb. The quantity of Ca in drainage water was considerably greater where K_2SO_4 was applied, than where it was not. There was less Mg present than Ca in both the plants and in the drainage. Like Ca its loss was decreased by cropping. Application of lime resulted in a liberation of Mg as indicated by its greater removal in the drainage water. Crops removed more K than did the drainage water Liming did not increase the K in the drainage water or in the crops. Applications of K_2SO_4 did not result in a larger removal of K in the drainage water or in the crops. The removal of S was much larger by the drainage water than by the crops. Of the S added to the soil in the form of K_2SO_4, more than ½ was removed in the drainage water. Liming slightly increased the leaching of S in the drainage water. There was never more than a trace of P in any of the tanks. Liming slightly increased the P content of crops from the limed tanks. C. R. FELLERS

Microbiological analysis of soils. T. BAUMGÄRTEL AND H. BUTENSCHON. *Landw. Jahrb.* **72**, 256–68(1930).—The authors extend and confirm the results of their previous work (*C. A.* **24**, 5909). By the use of Biejerinck's medium cultures taken from soils contg. increasing amts. of K. fertilizers show increasing development of *Azotobacter chroöcoccum*, and where heavy dressings of potash have been used there were large nos. of protozoa. GEORGE R GREENBANK

The value of the simplified Kappen method for determining absorbed bases. D. V. DRUZHININ AND Z. I. STROGANOVA. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 194–9(1930).—A series of tests was made on various soils comparing the Kappen and Bobko-Askinazi methods for detg. the absorbed bases The methods checked very well. The authors suggest a rapid, approx. method: To 1 part of soil (25, 40 or 50 g.) 2.5 parts of 0.1 *N* HCl is added, the mixt. is shaken for 1 min., allowed to stand 5 min., filtered and an aliquot taken and titrated with methyl orange as indicator. Tests with 16 different soils showed that the method checked very well with those of K. and of B.-A. Just as in the other methods the new method works best on soils free from lime and Ca phosphate and with a low content of absorbed bases. J. S. J.

The antimony electrode. M. S. DU TOIT. *South African J. Sci.* **27**, 227–35 (1930).—The Sb and H_2 electrodes were compared in a large no. of soils and found to agree closely. In the potentiometric titration of Fe and Al solns. the Sb electrode proved highly satisfactory. Its temp. coeff. was found to be 0.0013 v. per degree in

soils of varying p_H values. Franke and Willimans' conversion formula was confirmed. The use of the Sb electrode was advocated for soil surveys. C. E. P. JEFFREYS

An approximate method of mechanical analysis of soils for field purposes. P. KAMERMAN. *Soil Research* (Supp. to *Proc. Intern. Soc. Soil Sci.*) **2**, No. 2, 152–64 (1930). —A rapid method is described. The soil is dispersed by means of a mortar and rubber pestle after treatment with Na oxalate. In the case of certain soils the sample is pretreated with 0.2 *N* HCl or 6% H_2O_2. After a suitable period of settling, the clay fraction is estd. by detg. its sp. gr., and the sand fraction by decantation and measurement of its vol. I. A. DENISON

Neubauer analyses and field experiments. OBERDORFER. *Superphosphat* **6**, 83–5(1930). —In 28 field expts. on deep loam soils the crop responses to potash and phosphate fertilizers generally were in good agreement with the potash and phosphate deficiencies in the soils as indicated by Neubauer tests. K. D. JACOB

The methods of determining the phosphorus requirement of the soil. A. L. MASLOVA AND O. M. DOBROTVORSKAYA. *Udobrenie i Urozhai* (*Fertilizers and Crops*) **2**, 276–83(1930).—Soils from 27 field expts. were tested out in the lab. by the method of titration curves and soly. of P_2O_5. Into 100-cc. flasks 2, 4, 6, 9 and 12 cc. of 0.1 *N* HCl were introduced, 10 g. of soil was added and the whole made up to vol. After 24 hrs. the filtrates were analyzed for p_H and P_2O_5. It was found that for 2 different soils the soly. of P_2O_5 with HCl might be the same, but the p_H at which the same quantity of P_2O_5 is dissolved differs. Thus in chernozem soils the p_H value varies from 3.36 to 4.45, whereas in the dark gray loams it is 2.97. A comparison of the crop yields from the exptl. plots with the titration curves shows a certain correlation between the p_H and response to P fertilization. J. S. JOFFE
